THE process depends on the formation of methylene blue when dimethyl-*p*-phenylenediamine sulphate and ferric chloride are added in small quantities to a hydrochloric acid solution of hydrogen sulphide. The reagents are added in the order: hydrochloric acid, diaminesulphate and ferric chloride, in definite quantities as rapidly as possible, the temperature being kept constant. The colours are compared with standards prepared in a similar manner from solutions of known concentration of hydrogen sulphide (determined iodometrically) containing 10×10^{-6} to 3000×10^{-6} grm. per litre. The quantities recommended for 500 c.c. of solution are: 10 c.c. of concentrated hydrochloric acid, 25 mgrms. of diaminesulphate, and 2·5 c.c. of a 0·1 molar solution of ferric chloride dissolved in equal volumes of concentrated hydrochloric acid and water. The limits of the method are from 10×10^{-6} to 3000×10^{-6} grm. per litre.—W. H. P.

Hydrogen peroxide; The photochemical decomposition of ——. J. H. Mathews and H. A. Curtis. J. Phys. Chem., 1914, **18**, 166—178.

A MERCURY vapour lamp was used as the source of light and in order to maintain a constant illumination the lamp was surrounded by an air current of constant temperature, circulated through a Uviol-glass tube. The peroxide solution was contained in a Uviol-glass tube which was rotated by means of a pulley fixed at its upper end, its lower end being plugged with paraffin wax and resting on a spindle inside a larger tube of Uviol-glass through which was circulated a stream of water at constant temperature The decomposition was measured by titrating with permanganate and sulphuric acid. It followed the course of a unimolecular reaction and ceased abruptly on extinguishing the light. The temperature coefficient of the reaction was 1·5. Various substances acted as negative catalysts: sulphuric acid, sodium hydroxide, iodine, mercuric chloride, potassium cyanide, sodium thiosulphate, hydrogen sulphide, acetanilide, sodium chloride, calcium hydroxide and barium hydroxide. The case of sodium hydroxide was especially interesting as this substance acted as a powerful positive catalyst for the decomposition of hydrogen peroxide by heat.—J. B.

Bromine associated with chlorine in haloid salts; Use of telluric acid in the determination of ——. F. A. Gooch and H. I. Cole. Amer. J. Sci., 1914, **37**, 257—262.

TELLURIC acid may be used instead of selenic acid (see this J., 1913, 140) for the selective oxidation of hydrobromic acid in presence of hydrochloric acid, but it is necessary to add also sulphuric acid to liberate the hydrobromic acid from bromides. A weighed quantity of the haloid salts (chloride and bromide) is placed in a Voit distillation flask together with 1 grm. of telluric acid and water to make 40 c.c. The flask is connected by ground glass joints with a receiver containing 300 c.c. of a 1 per cent. solution of potassium iodide. 10 c.c. of sulphuric acid (1 : 1) are run into the distillation flask, a slow current of carbon dioxide is passed through the apparatus, and the reaction mixture is distilled until its volume is reduced to 17—18 c.c. The free iodine in the receiver is then titrated with thiosulphate. Under the conditions described up to 0·3 grm. of bromine (as bromide) can b accurately determined in presence of up to 0·25 grm. chlorine (as chloride).—A. S.

Carbon and graphite; Heat resistivity of —— J. W. Richards. Trans. Amer. Electrochem. Soc., 1913 **24**, 109—118.

A 20 cm. cube of the material, with a 2·5 cm. cubical cavity in its centre, was heated by an electric arc, the temperature within 1 mm. of the cavity being measured by a thermocouple inserted in a small hole 5 mm. in diameter. From measurements of the temperature of the outer faces the following results were obtained:—

National Carbon Co. carbon (202°—853° C.)=
36·8 thermal ohms per cm. cube.
Acheson graphite (240°—420° C.)=
3·69 thermal ohms per cm. cube.

In the discussion the necessity for recognising that the temperature of the inner surface is not necessarily that of the source of heat, but that it is determined by the outside temperature, the conductivity, and the thickness of the walls, was pointed out. Thus it is not necessary that the temperature of the gases in an open-hearth furnace be below the melting point of the roof bricks; it is in fact frequently some hundreds of degrees higher.—W. H. P.

Sodium chloride as a reagent for the detection of soluble silicates. Isnard. *See* XII.

PATENTS.

Nitrogen oxides or oxyacids; Process and apparatus for the manufacture of ——. A. H. Lymn, London. Eng. Pat. 3194, Feb. 7, 1913.

A TUBE containing a bed of porous, refractory material, such as fireclay, is heated by means of a combustible gas, and a mixture of nitrogen and oxygen is passed over it and combination induced inside and around the refractory mass; or the gases may be passed through the walls of a porous cylinder and caused to combine near its surface, which is thus raised to incandescence. Steam, superheated to the point of dissociation, may also be introduced into the gaseous mixture, in which case the reunion of hydrogen and oxygen causes an intensely high temperature, which promotes the combination of nitrogen and oxygen. To minimise dissociation, the nitrogen oxides, as soon as they are formed, are cooled, or absorbed by a suitable liquor. The gases may be admitted under pressure, at a reduced pressure, at a high velocity, or intermittently by means of a series of explosions.—O. R.

Sulphuric acid from the sulphur compounds of ammonia-freed coal-gas; Process for manufacturing ——, and apparatus therefor. J. Mackenzie, Middlesbrough-on-Tees. Eng. Pat. 4770, Feb. 25, 1913.

COAL-GAS, which has been cooled, condensed, scrubbed, and freed from ammonia, is passed through a series of purifiers containing ferric oxide. As soon as one of the purifiers is charged with sulphur, hot air is passed through it, and the sulphur dioxide which is formed, mixed with air, is passed successively through a contact chamber containing heated spent pyrites, a Glover tower, a sulphuric acid chamber, and a Gay-Lussac tower, for the manufacture of sulphuric acid.—O. R.

Metallic oxides or compounds [hydroxides]; Manufacture [by electrolysis] of ——. C. White, London. Eng. Pat. 4082, Feb. 17, 1913.

AN alkali chloride solution (20—25 per cent.) previously purified and containing ½—1 per cent. of alkali hydroxide, is heated to 98° C. and electrolysed, using as anode the metal (copper, zinc, lead, tin, bismuth) of which it is desired to form the oxide or hydroxide. A current density of about 100 amps. per sq. m. under a pressure of 1 volt may be employed.—O. R.

Salt; Manufacture of —— by multiple-effect evaporation. S. M. Lillie, Philadelphia, Pa. U.S. Pat. 1,086,457, Feb. 10, 1914.

In a multiple-effect evaporator for the manufacture of salt from brine, two or more evaporators communicate by way of a suitable conduit with a device for separating deposited salt crystals; suitable steam connections allow the evaporators at either end of the series to act alternately as the hottest and coldest end respectively, and provision is made for a flow of brine through the conduit, sufficiently rapid to carry salt, which is deposited in the conduit, into the separator.—O. R.

Thoria from monazite sand; Process of extracting ——. C. Baskerville, New York, Assignor to Welsbach Light Co., Gloucester City, N.J. U.S. Pat. 1,087,099, Feb. 17, 1914.

A mixture of monazite sand, carbon, lime, and calcium fluoride is heated to a temperature high enough to eliminate phosphorus and silicon from the sand, and to convert the metals into carbides, which are then disintegrated by slaking.—O. R.

Stannic chloride; Apparatus for the manufacture of ——. W. F. Doerflinger, Halesite, N.Y., Assignor to Niagara Alkali Co. U.S. Pat. 1,087,437, Feb. 17, 1914.

An apparatus for treating tin with hydrochloric acid comprises a reaction vessel fitted with a double locked inlet for the tin, an inlet for the acid, an internal appliance for regulating the temperature, and a number of independent temperature-regulating jackets.—O. R.

Potash salts from kelp; Process of obtaining ——. H. Wilson, Assignor to Pacific Kelp Co., San Francisco, Cal. U.S. Pat. 1,087,477, Feb. 17, 1914.

Kelp is allowed to decompose in a porous vessel until converted into a semi-solution; chlorides are deposited on the outside of the vessel as an efflorescence and are recovered. The kelp is then allowed to decompose further until the moisture has evaporated, water is added to the residue and nitrates are recovered in a similar manner as an efflorescence on the outside of the vessel.—O. R.

Dissolving salts, especially potassium salts, continuously in a counter-current apparatus. K. Kölichen and R. Meyer. Ger. Pat. 270,380, Dec. 2, 1910.

The cylindrical apparatus is divided into compartments by conical partitions disposed in pairs and communicating at their adjacent narrow ends by small openings. These partitions act as heating surfaces and the upper one of each pair, with its wide end uppermost, serves as a dissolving chamber. The material is introduced at the top of the apparatus and is carried downwards through the series of conical dissolving chambers by stirrers mounted on a central shaft, which also carries distributing plates. The solvent enters at the lower end of the apparatus and the solution leaves near the top. Steam for heating flows from above downwards through the heating chambers bounded by the conical partitions and the outer wall of the apparatus.—A. S.

Kieserite almost free from chlorine; Apparatus for obtaining ——. S. Haun. Ger. Pat. 270,193, June 20, 1913. Addition to Ger. Pat. 265,044.

In the apparatus described in the chief patent (this J., 1913, 1067), a screw is mounted in the tube through which the kieserite passes into the dish below. The kieserite is forced downwards by the screw and gradually fills the dish and is discharged slowly over the side. The dish may be replaced by a valve held in place by a spring or counterpoise until opened by the kieserite forced downwards by the screw.—A. S.

Nitrogen; Fixation of ——. J. E. Bucher, Providence, R.I., U.S.A. Eng. Pat. 27,713, Dec. 2, 1912.

See Fr. Pat. 455,799 of 1912; this J., 1913, 943. Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 5617 of 1881 and 1695 of 1908.—T. F. B.

Silicates containing potash; Process for producing from —— products which are richer in potassium oxide. P. Schneider, Cologne, Germany. Eng. Pat. 4403, Feb. 20, 1913. Under Int. Conv., Feb. 21, 1912.

See Fr. Pat. 454,632 of 1913; this J., 1913, 867.—T. F. B.

Alkali-metal compounds from silicates containing the same; Process of obtaining ——. A. Messerschmitt, Stolberg, Germany. U.S. Pat. 1,087,132, Feb. 17, 1914.

See Ger. Pat. 252,278 of 1911; this J., 1912, 1179.—T. F. B.

Alkalis from natural rocks; Method of extracting ——. A. Messerschmitt, Stolberg, Germany. U.S. Pat. 1,089,716, March 10, 1914.

See Ger. Pat. 264,900 of 1912; this J., 1913, 1066.—T. F. B.

Ammonium salts; Apparatus for manufacturing —— from ammoniacal substances. La Suburbaine (Vidanges et Engrais) Soc. Anon., Rueil, France. Eng. Pat. 4687, Feb. 24, 1913. Under Int. Conv., Feb. 24, 1912.

See Fr. Pat. 454,498 of 1913; this J., 1913, 882.—T. F. B.

Ammonia; Producing ——. C. Bosch and A. Mittasch, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,089,185, March 5, 1914.

See Addition of Aug. 13, 1912, to Fr. Pat. 431,295 of 1911; this J., 1913, 233.—T. F. B.

Ammonia; Process for the synthetic preparation of —— from its constituents. A. Matignon, Bourg-la-Reine, Assignor to Soc. Générale des Nitrures, Paris. U.S. Pats. 1,089,240 and 1,089,241, March 3, 1914.

See Fr. Pat. 430,595 of 1910; this J., 1911, 1381.—T. F. B.

Radiothorium; Process for the preparation of ——. P. M. Justice, London. From O. Knöfler und Co., Berlin. Eng. Pat. 5960, March 10, 1913.

See U.S. Pat. 1,076,141 of 1913; this J., 1913, 1116.—T. F. B.

Hydrogen peroxide; Manufacture of ——. H. Wade, London. From Henkel und Co., Dusseldorf, Germany. Eng. Pat. 10,476, May 3, 1913.

See Fr. Pat. 457,696 of 1913; this J., 1913, 1010.—T. F. B.

Chlorate solutions; Process for activating ——. K. Hofmann, Charlottenburg, Germany. Eng. Pat. 20,593, Sept 11, 1913. Under Int. Conv., Nov. 19, 1912.

See Ger. Pat. 267,906 of 1912; this J., 1914, 200.—T. F. B.

Lime in block form; Process for the production of ——. F. Neumerkel, Budapest. Eng Pat. 22,924, Oct. 10, 1913. Under Int. Conv., April 14, 1913.

See Fr. Pat. 461,359 of 1913; this J., 1914, 260.—T. F. B.

Aluminosilicates or artificial zeolites; Process of making hydrated ——. R. Gans, Pankow, Assignor to J. D. Riedel A.-G., Berlin. Reissue No. 13,691, Feb. 24, 1914, of U.S. Pat. 914,405, March 9, 1909.

See Eng. Pat. 8232 of 1907; this J., 1907, 1091.—T. F. B.

Hydrated alumino-silicates, or artificial zeolites, and process of producing same. R. Gans, Pankow, Assignor to J. D. Riedel A.-G., Berlin. Reissue No. 13,688, Feb. 17, 1914, of U.S. Pat. 943,535, Dec. 14, 1909.

See Fr. Pat. 374,525 of 1907; this J., 1907, 872.—T. F. B.

Tin tetrachloride; Process of producing ——. Obtaining tetrachloride of tin from tin-scrap and other materials containing tin. P. Wolff, Wetzlar, Germany, Assignor to Vulcan Detinning Co. U.S. Pats. 1,087,522 and 1,087,523, Feb. 17, 1914.

See Fr. Pat. 405,851 of 1909; this J., 1910, 424.—T. F. B.

Bisulphites; Process of stabilising ——. L. Nonnet, Brussels. U.S. Pat. 1,087,547, Feb. 17, 1914.

See Fr. Pat. 450,804 of 1912; this J., 1913, 602.—T. F. B.

Titanium cyanonitride; Process of producing ——. S. Peacock, Chicago, Assignor to E. I. du Pont de Nemours Powder Co. U.S. Pat. 1,088,359, Feb. 24, 1914.

See Eng. Pat. 11,392 of 1912; this J., 1913, 600.—T. F. B.

Electrolysis of alkali or alkaline-earth chlorides; Process for the ——. A. Clemm. Fr. Pat. 463,395, Oct. 8, 1913. Under Int. Conv., Dec. 3, 1912.

See Eng. Pat. 21,462 of 1913; this J., 1914, 312.—T. F. B.

Phosphorus pentachloride; Process for producing ——. S. Peacock. Fr. Pat. 463,497, Oct. 10, 1913.

See Eng. Pat. 23,023 of 1913; this J., 1914, 256.—T. F. B.

Sodium bisulphate; Process for making —— in a form which can be calcined directly. Akt.-Ges. Dynamit Nobel. Fr. Pat. 464,097, Oct. 23, 1913. Under Int. Conv., Jan. 22, 1913.

See Ger. Pat. 263,120 of 1913; this J., 1913, 909.—T. F. B.

Hydrogen; Production of ——. A. Messerschmitt, Stolberg, Germany. Eng. Pat. 18,028, Aug. 7, 1913. Under Int. Conv., Jan. 10, 1913.

See Fr. Pat. 461,480 of 1913; this J., 1914, 200.—T. F. B.

Oxygen [from air]; Apparatus for the manufacture of ——. E. F. Aumont, Paris. U.S. Pat. 1 088,052, Feb. 24, 1914.

See Eng. Pat. 11,306 of 1911; this J., 1912, 230.—T. F. B.

Hydrogen and oxygen; Electrolytic production of ——. The Knowles Oxygen Co., Ltd., and R. W. Grant. Fr. Pat. 463,507, Oct. 10, 1913.

See Eng. Pat. 1812 of 1913; this J., 1914, 24.—T. F. B.

Collection and separation of finely divided sulphur. Eng. Pat. 26,594. *See* X.

Electrolytic generator [for hydrogen and oxygen]. U.S. Pat. 1,087,937. *See* XI.

VIII.—GLASS; CERAMICS.

Transparent quartz; French manufacture of —— and its applications. Mercury vapour lamps. J. Gallois. Bull. Soc. d'Encour., 1914, **121**, 205—212.

Dependent till 1911 on English and German imports, the French now manufacture their own silica ware, a factory at Laigneville producing fused quartz which allows the whole mercury spectrum down to 2302 Angström units to pass through a thickness of 3 mm. of the medium, a transparency to ultra-violet rays which permits of its application to the sterilisation of liquids in addition to industrial illumination and chemical ware. A new mercury vapour lamp with quartz illuminating tube is described. In the initial position the mercury fills the illuminating tube, but when the current is started, a coil attracts an armature connected by a rod with the tube, and turns the latter on its axis about 40° whereby in consequence of the shape of the tube the mercury is divided into two portions and an arc is formed across the intervening space. Quartz lamps are constructed to work under tensions of 220 to 500 volts, giving a candle-power of 500—6600. The most powerful will illuminate an area of 2 hectares (5 acres).—H. H. S.

Patents.

Oil fired furnaces for melting glass or other fusible substances. A. A. Mohn, London. From J. Rothkopf, Paris. Eng. Pat. 26,494, Nov. 18, 1912.

A continuous furnace is provided with an arched double roof, the hot combustion gases returning through the space thus enclosed, with the result that a more intense and regular heat is reflected on to the material to be melted in the furnace, whilst the waste gases are utilised for the production of superheated steam which is employed to break up and spray the heavy liquid hydrocarbons used in the burner.—H. H. S.

Refractory products of quartz and similar materials; Manufacture of ——. W. Boehm. Fr. Pat. 463,147, Oct. 2, 1913.

Silica or zirconia is rendered conducting by addition of soda or potash lye and then fused by electric current, the heating being continued until the alkali is volatilised. The ware is shaped in the fused condition.—H. H. S.

Bricks; Methods and apparatus for the burning and like treatment of ——. E. C. R. Marks, London. From A. A. Scott, Knoxville, Tenn., U.S.A. Eng. Pat. 4286, Feb. 19, 1913.

Dried bricks are placed in a series of closed self-contained communicating kiln chambers, each forming in itself a complete kiln and having its own combustion chamber. The chambers are mounted on suitable trucks moving on a track through a tunnel of sufficient height to leave a drying chamber for wet bricks above the train. Means are provided for the introduction of fuel into each kiln-chamber, and flues connect the rear end of one with the forward end of its successor throughout the train. When the bricks in the middle kiln are burned, the train is advanced one chamber, a new kiln filled with dried hot bricks being added at the rear.—H. H. S.

Earthenware; Methods of placing articles of —— and the like in firing ovens and in saggers. W. Hassall, Burton-on-Trent. Eng. Pat. 14,325, June 20, 1913.

Lavatory basins and similar articles are supported in firing or glazing ovens by floors or shelves extending only partly across the area of the saggers so that the articles overlap one another vertically, the saggers of each "bung" or stack being arranged so that floors and spaces alternate in position.—H. H. S.

Abrasive compounds; Method of producing ——. T. B. Allen, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,087,705, Feb. 17, 1914.

A molten magma having substantially the theoretical composition of garnet is allowed to cool slowly to permit of the crystallisation of garnet, and then quickly—for example, by crushing in water—in order to prevent dissociation of the garnet.—H. H. S.

Polishing material; Manufacture of —— from bauxite. E. Strasser. Fr. Pat. 463,570, Oct. 13, 1913.

Bauxite rich in iron is calcined at 1200°—1400° C., with addition of a reducing agent such as common salt and carbon, which will form a volatile compound of iron, and the residual alumina is fused in an electric furnace.
—H. H. S.

Ceramic materials and products; Manufacture of ——. T. Moses. Fr. Pat. 463,899, Oct. 27, 1913.

Fragments of porcelain, faience and glass, free from iron, are mixed in the proportions 100 : 35 : 20, powdered, and treated as in the manufacture of glazed tiles.—H. H. S.

Metal articles; Cleaning of —— preparatory to the application of a coating of enamel or the like. T. R. Davidson, Westmount, Quebec, Canada. Eng. Pat. 16,554, July 18, 1913.

The metal articles, such as sheet iron or steel, are first immersed in concentrated sulphuric acid to carbonise grease, etc., then allowed to stand in water, when the carbonised matter settles, and the dilute acid formed further cleanses the metal. Finally they are washed in clean water heated preferably to near the boiling point, and dried.—T. St.

Enamelling sheet-iron and the like: Process for ——. L. Honigmann, Aachen, Prussia. Eng. Pat. 28,398, Dec. 9, 1913. Under Int. Conv., April 4, 1913.

Metallic silver is used in the undercoat as a substitute for cobalt or nickel oxide, or for a silver compound in solution, in order to make the enamel more flexible and adherent.—H. H. S.

Enamels; Manufacture of white ——. Verein. Chem. Fabr., Landau, Kreidl, Heller und Co. Fr. Pat. 463,623, Oct. 14, 1913. Under Int. Conv., Oct. 22, 1912.

Oxides and silicates, *e.g.*, of zirconium, titanium, aluminium and tin, suitable for use as agents for producing opacity, are finely ground and treated in the enamel mill with very dilute acid or alkali, by absorption of which they become capable of combining with water. Formation of sols is avoided by addition of crystalloids.—H. H. S.

IX.—BUILDING MATERIALS.

Portland cement; Determination of the finest flour in ——. A. Hauenschild. Tonind.-Zeit., 1914, 38, 477—478.

Portland cement was divided into fractions of different legrees of fineness by first passing it through a sieve with 900 meshes per sq. cm. and then grading the finer ortion in an air centrifuge, the material being fed through hopper on to a distributing plate, on leaving which it vas subjected to the action of a centrifugal air current, roduced by a fan rotating at 2180 revs. per min. In his way considerable quantities of the material were reated, the different fractions being collected in a series f concentric receptacles. The finest fraction contained he greater part of the sulphates present in the cement. he various fractions did not differ much in composition xcept in regard to the loss on ignition, which was greatest the finest fraction, and decreased progressively with e decrease of fineness. The time of setting was accelerated, the volume-weight decreased, and the volume-nstancy increased with increasing fineness. The greatest rength was possessed by Portland cement grains the mensions of which were between 0·0363 and 0·0197 mm. he finest flour, less than 0·007 mm. in size, rapidly sorbed carbon dioxide and water, and was therefore not lapted to yield cement of the greatest strength.—O. R.

rtland cement; The iron in ——. H. Kühl. Tonind.-Zeit., 1914, 38, 537—540.

x groups of cements were prepared, all having the same icate modulus, or ratio of silica to alumina plus ferric ide, viz., 1 : 1·90, but with the percentage ratio $_2O_3 : Fe_2O_3$ varying in the different groups from 84 : 0·63 to 0·19 : 10·85. In each group, the proportion of lime only was allowed to vary. The highest portion of lime which could be safely introduced was siderably higher with the cements rich in alumina n with those rich in ferric oxide, the limiting values the "hydraulic modulus" being 1 : 2·3 and 1 : 2·0 pectively. Within the limits for a true Portland ent (silicate modulus, 1 : 1·2 to 1 : 4·0), the highest sible proportion of lime is given by the formula, $CaO,SiO_2+y,3CaO,Al_2O_3+z,3CaO,2Fe_2O_3$. A micropic study of cement clinker containing varying protions of ferric oxide indicated that iron compounds act beneficially as a flux in bringing about sintering, which is necessary for the proper formation and crystallisation of the clinker minerals.—F. Sodn.

Blast furnace slag in Portland cement; Determination of ——. F. Hart. Z. Unters. Nahr. Genussm., 1914, 27, 286—290.

The material is dried at 105° C. and the fine meal of Portland cement removed through a sieve with 5000 meshes per sq. cm. The residue is washed with alcohol and ether, dried, and particles of iron removed by a magnet. Twenty grms. are then submitted to systematic fractionation by shaking with mixtures of benzene and methylene iodide of sp. gr. 3·05, 3·00, 2·96, and 2·70 respectively, so as to obtain five fractions: (1) sp. gr. above 3·05 (cement clinker), (2) sp. gr. 3·0—3·05 and (3) sp. gr. 2·96—3·0 (mixtures of cement and slag), (4) sp. gr. 2·70—2·96 (slag), and (5) sp. gr. below 2·7 (coke, ash, gypsum, and slag). Fractionation is continued until portions 1 and 4, examined microscopically (and, if desired, by chemical analysis), are found to be pure, and the sulphide sulphur is then determined in each, as well as in the original cement. The percentage of added slag is given by the formula, $H = 100\frac{a-b}{c-b}$, in which a is the sulphide content of the cement, b and c that of fractions 1 and 4 respectively. The method is inapplicable if more than one kind of slag be present.—F. Sodn.

Patents.

Ovens and kilns; Bricks or quarries for use in the bottoms of ——. C. T. H. Phillips, Burslem, Staffs. Eng. Pat. 3613, Feb. 12, 1913.

The brick or "quarry" is formed with one or more semicircular indentations at its longitudinal and transverse edges, so that when one row of bricks on edge is bridged over with similar bricks on the flat, passages are formed for the circulation of air. (Reference is directed to Eng. Pats. 8561 of 1890, 18,730 of 1892, 21,256 of 1895, 9948 of 1905, and 8362 of 1911.)—O. R.

Refractory brick. H. Wessling, Hays Station, Pa. U.S. Pats. 1,088,755 and 1,088,756, March 3, 1914.

Fine particles of silica are bonded together by finely pulverised soapstone in the proportion of 6000 lb. to 150 lb. A smooth surface is obtained by dipping the brick in a bath of powered silica and water before drying and burning.—H. H. S.

Portland cement; Application of the waste from sugar-refineries to the manufacture of an artificial ——. Soc. Anon. des Etablissements A. Maguin. First Addition, dated Dec. 12, 1912, to Fr. Pat. 460,438, Oct. 4, 1912 (this J., 1914, 27).

The coal for firing the kiln passes first through a drying tube, and is then raised by an elevator into a hopper whence it is fed to a double tube grinding mill. The powdered coal is delivered by an elevator to a screw conveyor leading to the kiln, any surplus being returned by another screw conveyor to the elevator.—A. T. L.

Artificial stone; Porous —— and its production. J. W. Aylsworth, East Orange, and F. L. Dyer, Montclair, N.J. U.S. Pat. 1,087,098, Feb. 17, 1914.

Powdered aluminium and a small quantity of slaked lime are added to mixtures containing Portland cement, whereby hydrogen is evolved on the addition of water, with the formation of porous artificial stone.—O. R.

Cement, concrete and the like in briquette form; Apparatus for applying tensile and compressive tests to ——. A. K. Bamber, London. Eng. Pat. 6645, March 18, 1913.

The use of two separate machines in carrying out tensile and crushing tests is avoided by an apparatus comprising a fixed frame carrying an abutment for compression tests, and having a cross member provided with a jaw for tensile tests. A movable frame mounted so as to slide within the fixed frame and carrying a complementary abutment and a complementary jaw, is forced upwards by compressed liquid and exerts a tensile strain on the test briquette held by the jaws and a crushing strain on that between the abutments.—H. H. S.

Alkaline cements. J. H. Amies. Philadelphia. U.S. Pats. 1,087,914 and 1,088,646. Feb. 24. 1914.

Dry cement powders capable of being shipped in bags, and of securing the set of natural soil when mixed with such soil and water, are composed of: (1) 60 parts of Portland cement, 30 of calcium hydroxide, and 10 of soda ash or other water-soluble alkali; (2) 50 parts of Portland cement, 30 of calcium hydroxide and 20 of plaster of Paris.—H. H. S.

Concrete; Process of waterproofing ——. A. E. Horn, New York. U.S. Pat. 1,088,022, Feb. 24, 1914.

Ammonium stearate, or other ammonium soap unstable in air and free from other alkali, is added to the water used for gauging the concrete.—H. H. S.

Refractory brick [for lining rotary kilns]; Manufacture of —— from cement. Soc. J. et. A. Pavin de Lafarge. Fr. Pat. 463,394. Oct. 8. 1913.

To render bricks made from Portland cement clinker more durable small quantities of calcium fluoride and calcium chloride are added. The bricks are made by agglomerating with calcium fluoride, and chloride, powdered Portland cement clinker containing SiO_2 20—30, $Al_2O_3+Fe_2O_3$ 2—5, and CaO 65—70 per cent. The quantity of fluorine should not exceed 1 per cent. of the whole mass.—A. T. L.

Cement or artificial stone; Process for colouring —— with substances having a basis of kaolin or other aluminium silicates and prepared by special methods. A. J. Caubel. Fr. Pat. 464,057. Sept. 27, 1913.

A chrome green is prepared by mixing finely powdered kaolin with sodium bichromate, making into a paste with a 5 per cent. solution of common salt and a 1 per cent. solution of sodium silicate, drying and calcining in a reducing atmosphere. Cobalt blue is prepared similarly from kaolin and the double chloride of sodium and cobalt, and a red material from kaolin and ferrous sulphate. A lead chromate colour is made by precipitating with bichromate a boiling mixture of kaolin and lead acetate. Similar products may also be prepared by treating a paste consisting of kaolin and sodium silicate with an aqueous solution of the colouring matter, boiling, and precipitating with sodium carbonate and alum. For colouring cement and artificial stone, the materials prepared as described are boiled with a solution containing caustic soda, 2, and sodium carbonate 5 per cent., decanted and filtered. The dry colour is then mixed with cement and sand and water.—A. T. L.

Plaster of Paris; Kiln for burning ——. M. F. Clément Fr. Pat. 463,242. Dec. 11, 1912.

The material is supported in the kiln on a perforated floor through which are admitted the heating gases from furnaces or producers. Air is delivered to the latter by a blower, and dampers are arranged so that part of the air can be delivered above the fuel in order to regulate the temperature of the heating gases for the kiln. The air is preheated in a jacket enclosing the furnace or producer. To ensure a uniform temperature in the kiln, a perforated partition is arranged above the charge so that the gases passing through the charge are under slight pressure. —A. T. L.

Artificial wood; Manufacture of ——. McTavish, Ramsay and Co., and A. L. Ramsay, Dundee. Eng. Pats. 7038, March 25, and 12,286, May 27. 1913.

Sawdust is mechanically reduced or ground, preferably with the aid of heat and with addition of 0·5 per cent. of caustic potash. It may then be subjected, in a closed vessel, to alternating vacuum and release, after which a pressure of 3 lb. per sq. in. is applied till the mass softens. It is next mixed with 5 per cent. of cellulose acetate and with chemicals, *e.g.*, caustic alkali, or rosin size, or soda and alum, with or without jute or hemp waste previously steeped in hot caustic. The mass is finally compacted by alternate drying and pressing. The proportions of the ingredients may be: sawdust 70, jute waste 20, cellulose acetate 5, chemicals 5, per cent.—H. H. S.

Wood and other porous bodies; Apparatus for the impregnation of ——. F. Moll. Fr. Pat. 463,630. Oct. 14, 1913. Under Int. Conv., Oct. 16. 1912.

The vessels in which wood, etc., is treated under pressure with a solution of mercuric chloride, copper sulphate, or acid zinc fluoride are made of materials not attacked by the solution, such as cement, concrete, masonry or wood. The wood, etc., is carried on a wooden trolley running on hardwood balls or rollers. The pipe connections between the impregnating vessel and the reservoir containing the impregnating solution are of earthenware cased in iron, or of iron lined with ebonite.—A. T. L.

Wood and other vegetable substances; Preservation of ——. J. Gerlache. Fr. Pat. 464,117, Oct. 25. 1913.

Wood, etc. is treated with an ammoniacal solution of chromite, arsenite, antimonite or antimoniate of copper, zinc, cadmium, cobalt or nickel. These salts are insoluble in water and do not wash out of the wood. Caustic soda or other alkali is added to the solution in order to prevent the liberation of chromic or other oxidising acid in the wood. The ammoniacal solution may be made with salts such as copper sulphate or zinc chloride, with the addition of chromic or other similar acid and a strong alkali.—A. T. L.

Slabs, blocks, bricks, plates, boards, and the like from blast furnace slag; Manufacture of light ——. Manufacture of porous slag. Production of porous slag for use as an aggregate. C. H. Schol. Allendorf, Germany. Eng. Pats. 28,642, Dec. 12, 1912. and 838 and 839 of 1914, dates of appl., Dec. 12. 1912.

See Addition of April 12, 1913. to Fr. Pat. 437,595 of 1911: this J., 1913, 1012.—T. F. B.

Concrete, cement, and the like; Manufacture of products of ——. H. S. Owen, Salt Lake City. U.S. Pat. 1,087,974, Feb. 24, 1914.

See Eng. Pat. 8085 of 1911; this J., 1911. 1255.—T. F. B.

Impregnating porous substances [wood, etc.]; Apparatu for ——. W. J. Frame and H. L. Galloway. Fr. Pat 463,650. Oct. 15, 1913. Under Int. Conv., Nov. 1, 1912

See Eng. Pat. 25,029 of 1912; this J., 1914, 315.—T. F. B

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Russian platinum production in 1913. Board of Trade March 19. 1914. [T.R.]

H.M. Commercial Attaché for Russia reports that t yield of platinum in the Urals continued to decrea in 1913 in spite of the very high prices prevailing. Accor ing to the "Torgovo-Promyshlennaya Gazeta" (Petersburg) of Feb. 24, the production in 1913 w 299 pouds 18 funts, as compared with 337 pouds 9 fu in the previous year (40 funts=1 poud=526·64 oz. Tro

Iron: On the structural changes of —— during anneali D. Ewen. Int. Zeits. Metallog., 1914, **6**. 1—17

Thin strips of polished Swedish wrought iron of gr purity were heated at various temperatures *in vacuo* the surface network ("heat-relief") produced, examined. In a strip in which the temperature rose from 620° C. at one end to 830° C. at the other, a simple and continuous heat relief over the whole surface was obtained, indicating that the transformation at the A2 point involves no change of crystalline form. A strip in which the temperature ranged from 800° C. to 970 C. showed a structural change point corresponding to the A3 inversion. The portion which had been heated above the A3 point showed the heat relief corresponding to the original α- and β-iron, the γ-iron structure, and the final β- and α iron structure produced on cooling. Strips which were heated by an electric current showed considerable pitting. The development of the α-iron structure at temperatures below 760° C. was probably due to selective volatilisation from the crystal boundaries, and γ-iron, and the final β- (and α-) iron heat reliefs produced on cooling, to differences in dilatation of the allotropic modifications.—T. St.

Carbon steel; Thermal expansion and rate of solution of ——. J. Driesen. Ferrum, 1914, 11, 129—138, 161—169.

Steel containing C 0·05—3·9 per cent. and very small amounts of impurities, was tested over a temperature interval of 20°—1000° C., the heating and cooling curves being determined for both annealed and chilled bars. At 180° C., annealed carbon steel showed irregularities of expansion which indicate a transformation of the cementite. Ferrite and β-cementite (stable above 189° C.) had practically the same coefficient of expansion; that of α-cementite (below 180° C.) was smaller. With more than 0·85 per cent. C. the coefficient of expansion showed a well-defined maximum at 1·7 per cent. A maximum of contraction in the transition interval was observed for a carbon content of 0·33 per cent. Chilled steel, even when very poor in carbon, contracted at 275°—340° C.; the irregular expansion occurring at 100°—150° C. was observed for a minimum content of 0·6 per cent. C. Chilled steel showed permanent contraction on tempering; 0·9 per cent. C. caused a maximum contraction. The rate of solution of chilled carbon steel in $N/10$ sulphuric acid was greatest after tempering at 350°—420° and lowest at 100°—200° C. These ranges of temperature were the same as those of irregular expansion, and the curve showing the influence of carbon on the rate of solution of tempered steel, disclosed an irregularity at 0·9 per cent. C.—W. R. S.

Cyanide solutions; Electrolysis of ——. E. F. Kern Trans. Amer. Electrochem. Soc., 1913, 24, 241—270.

Electrolysis of cyanides with direct current and insoluble anodes, was accompanied by consumption of cyanide due to oxidation. Anodes of iron, nickel, or lead were dissolved, and immediately precipitated—the lead as hydroxide, the other metals as mixtures of hydroxide and cyanogen compounds, the consumption of cyanide being greater the lower the current density, since at high current density oxygen was evolved and less metal dissolved. The consumption was least with the lead anodes. Peroxidised lead and passive iron anodes were more permanent than those of the pure metals, and were not corroded so long as they were not exposed to the air. The passive iron was superior to the peroxidised lead. Electrolysis of cyanide solutions used for leaching a refractory gold and silver ore containing sulphides, did not reduce cyanide consumption, nor give a greater extraction. Low current density at both the anode and the cathode seemed to produce some "active" solvent but not enough to compensate for loss in electrolysis. The lower the current density at the anode and the higher at the cathode, the greater was the relative cyanide consumption. When solutions containing thiocyanate or ferrocyanide were electrolysed, the loss of cyanide was greatly diminished, whilst increasing alkalinity reduced the loss of cyanide by increasing the conductivity. Peroxidised lead and passive iron anodes were corroded in the presence of thiocyanate at current densities above 32 amp. per sq. m. The regeneration of cyanides containing thiocyanate and ferrocyanide did not occur in electrolysis with direct current.—W. H. P.

Alkali cyanides; Electrolysis of aqueous solutions of simple ——. G. H. Clevenger and M. L. Hall. Trans. Amer. Electrochem. Soc., 1913, 24, 271—296. (See preceding abstract.)

Most of the decomposition during electrolysis of a cyanide was found to be due to oxygen liberated at the anode through decomposition of water. The principal final reaction in alkaline cyanide solutions (usually containing lime) was the formation of carbonate. In technical electrolytic regeneration, more cyanide might be decomposed than regenerated by precipitation of the metal in solution, and in the treatment of refractory ores the electrolysis might actually interfere with extraction, by forming a coating of calcium carbonate on the ore particles. The Liebig method of titration in estimation of cyanides, gave low results for electrolysed solutions, and fresh and electrolysed cyanide solution underwent different changes on standing. In fresh solution the changes were due to exposure to air. In the electrolysed solution the changes were due to further reactions between the dissolved substances, which varied with the extent and nature (KOH or $Ca(OH)_2$) of the original alkalinity.—W. H. P.

Gold; Resistivity of pure —— in the temperature range 20° C. to 1500° C. E. F. Northrup. J. Franklin Inst., 1914, 177, 287—292.

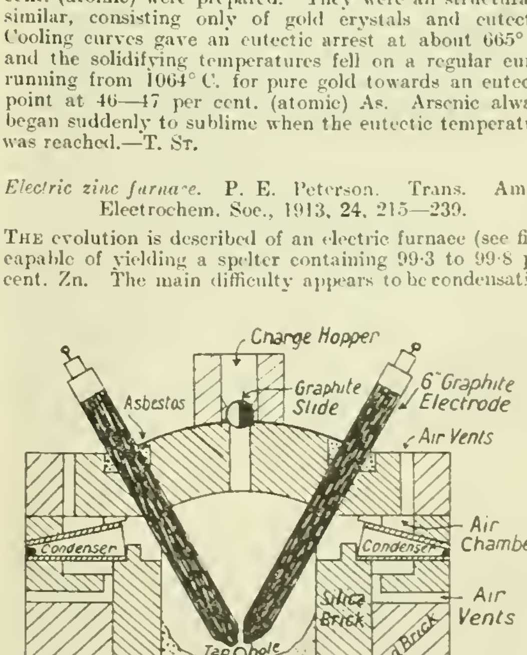
The same method was employed as for copper (see this J., 1914, 141 and 264). The values obtained were: 20° C., 2·317; 300°, 4·72; 500°, 6·62; 800°, 9·94; 1000°, 12·54; 1063°, (solid), 13·50; 1063° (molten), 30·82; 1100°, 31·34; 1200°, 32·76; 1300°, 34·17; 1400°, 35·58; and 1500° C., 37·00 microhms per cm.³. The curves show that the resistivity changes in a linear manner with temperature, both in the liquid and solid conditions.
—W. H. P.

Gold and arsenic; Alloys of ——. A. P. Schleicher. Int. Zeits. Metallog., 1914, 6, 18—22.

Alloys of gold and arsenic containing As up to 25·47 per cent. (atomic) were prepared. They were all structurally similar, consisting only of gold crystals and eutectic. Cooling curves gave an eutectic arrest at about 665° C., and the solidifying temperatures fell on a regular curve running from 1064° C. for pure gold towards an eutectic point at 46—47 per cent. (atomic) As. Arsenic always began suddenly to sublime when the eutectic temperature was reached.—T. St.

Electric zinc furnace. P. E. Peterson. Trans. Amer. Electrochem. Soc., 1913, 24, 215—239.

The evolution is described of an electric furnace (see fig.) capable of yielding a spelter containing 99·3 to 99·8 per cent. Zn. The main difficulty appears to be condensation and excessive formation of "blue powder." The solution of this involves the maintenance of a sufficient condensing



area at the right temperature (about 850° C.) near the source of volatilisation. In working the charge must be carefully mixed. A matte must be made of uniform composition and in sufficient quantity to effect a good saving of gold, silver, and copper. The nature and proportion of the reducing carbon are all important. Physically the charge must be fairly but not too finely divided, and perfectly dry, which involves the use of a preheating furnace for the whole charge. The matte is regulated by adjusting the percentage of sulphur in the calcined ore, about 5—7 per cent. being the best proportion. The paper contains suggestions for the treatment of blue powder, and for the improvement of condensation, together with details of the costs for the furnace worked out on a one ton unit. —W. H. P.

Brass ; Resistivity of solid and molten ——. E. F. Northrup. Met. and Chem. Eng., 1914, **12**, 161—162.

THE resistivity of brass containing Cu 63, Zn 34·6, and Pb 2·4 per cent. was measured from the temperature of melting down to the ordinary temperature and again up to 1104° C. Vaporisation of zinc was inappreciable under 1090° C. The resistivity of the rod-brass was found to be 7·101 microhms per cm³. at 20°, and 7·550 at 50° C. ; after cooling from the molten state it was 6·957 microhms at 20° C. The brass was molten at 972° C., and the ratio of resistivity just after fusion, to that just before fusion, was 2·37+. When molten the resistivity decreased with increase in temperature, being 41·20 microhms per cm.³ at 1000°, and 40·11 at 1084° C. At about 1090° C. the decrease became less rapid, indicating loss of zinc by vaporisation. Determinations of resistivity might be employed with advantage to detect alterations in composition, and generally, in studying the properties, of alloys. —W. R. S.

Corrosion ; Microchemistry of ——. [*Copper-zinc alloys.*] S. Whyte and C. H. Desch. Inst. of Metals, Jnl., 1913, **10**, 302 ; and March, 1914 [advance proof].

THE alloys were subjected to electrolytic corrosion over a definite area in a 5 per cent. solution of sodium chloride. Three β- (Zn 47 per cent.) and four α-brasses (Zn 30 per cent.) were examined, two of the former containing Sn 1 and Fe 1 per cent., and three of the latter Sn 1, Pb 1, and Pb 2 per cent. respectively. β-Brass was corroded more after quenching from above the transformation point (470° C.) than when slowly cooled : iron accelerated corrosion, and tin retarded it, chiefly owing to the formation of a tough adherent coating of basic salts. α-Brasses were corroded less than the β-alloys : tin accelerated corrosion at first, but retarded it subsequently. Corrosion was not retarded by 1 per cent. Pb, but the alloy with 2 per cent. Pb was less corroded than any of the others, a very firmly adherent layer being formed. The microstructure of a brass condenser tube corroded during service was reproduced by electrolytic corrosion in the laboratory. Corrosion of Cu-Zn alloys is preceded by dezincification, the residual spongy copper being converted into oxide as fast as it is formed when corrosion is slow and an abundant supply of oxygen is present, whilst otherwise a metallic layer free from zinc is left. —A. S.

Copper ore in Scotland. Times, March 30, 1914. [T.R.]

A PROMISING copper mine has been opened up on the estate of Otter, in Argyllshire, as the result of the chance discovery some years ago of a piece of ore ; no copper is shown on the geological map of Scotland for that district. Three rich lodes have been opened at Inveryne, Tighanraed, and Kilfinan. The operations have so far been mainly devoted to the last named, which is by far the richest. Work has now been going on for about 14 months, and 266 tons of selected ore, giving an average yield of 15 per cent., have already been sent to the smelters, in addition to which 70 tons of "dump" have averaged 3½ per cent. The average yield of the ore taken from the lode is expected to be 8 to 10 per cent.

When operations were commenced at Kilfinan the prospectors found a vertical vein of copper carbonate about 2 in. thick, which when followed for about 40 ft. expanded into a solid mass of grey sulphide 1 ft. or 2 ft. thick. There is an ample water supply and good timber in the neighbourhood, while the property is close to tidal waters.

Alloys of copper, nickel and aluminium. L. Guillet. Comptes rend., 1914, **158**, 704—706.

THE result of adding aluminium to Cu-Ni-alloys is illustrated in tables summarising the mechanical properties of three series of such alloys containing, respectively, Cu 60, 83 and 90 per cent. with gradually increasing percentages of aluminium up to 10. Traces of iron were also present. With progressive addition of aluminium, hardness and tenacity rapidly attained a maximum and then declined, although not concurrently. 15 per cent. Al rendered the alloys very brittle.—J. R.

Lead ; Solid, thick deposits of —— *from lead acetate solutions.* F. C. Mathers. Trans. Amer. Electrochem. Soc., 1913, **24**, 315—329. (See also this J., 1913, 429.)

THE best addition agent for producing good deposits from lead acetate solution, appears to be peptone in the presence of ammonium or sodium perchlorate and acetic acid. The amount of peptone must not be too small or a fringe of crystals will be obtained, whilst if too large, the deposits will be rough and brittle. The best current density is about 0·4—0·8 amp. per sq. cm. and the best concentration of lead acetate 6—10 per cent. The only salt capable of replacing the perchlorate is sodium naphthalenesulphonate (2 per cent.) ; this gives a heavy precipitate insoluble in acetic acid, and the bath, after filtration, yields excellent deposits of lead. Potassium perchlorate is too insoluble to be convenient, and sodium chloride always deleterious. Although glue, and the extract from feathers with glacial acetic acid, give fairly satisfactory deposits, no other addition agent has been found to replace peptone.—W. H. P.

Chromium, tungsten, molybdenum and vanadium ores ; Electric smelting of ——. R. M. Keeney. Trans. Amer. Electrochem. Soc., 1913, **24**, 167—189.

REFERRING to the more rarely mined minerals of the western States of America the author points out that ferrochrome can be manufactured directly from chromite in the electric furnace. The carbon content cannot be kept low by regulating the amount charged without excessive loss of chromium in the slag, but can be reduced by decarburising with an oxide slag after tapping off the slag from the reduction. Silicon and phosphorus cannot be kept low under the strong reducing conditions, but sulphur is easily slagged. Lime should not be used as it does not assist in removing the phosphorus. The power consumption should not be more than 3·7 kilowatt-hours per lb. of ferrochrome tapped, and the electrode consumption not more than 50—100 lb. per 2000 lb. of metal produced. Ferrotungsten can readily be obtained from ferberite ($FeWO_4$) ; with the use of a decarburising slag the carbon can be kept below 2 per cent. Manganese, silicon, phosphorus, and sulphur do not enter the alloy in large quantities and the loss of tungsten in the slag need not be excessive. The power consumption need not be more than about 3·5 kilowatt-hours per lb. of metal tapped. Molybdenite will yield ferromolybdenum low in carbon, and sulphur can be readily slagged in the presence of excess of lime. Vanadium alloys can also be obtained in similar ways from the oxide or from patronite a Peruvian sulphide ore.—W. H. P.

Strontium ; Preparation of metallic ——. B. Neumann and E. Bergve. Z. Elektrochem., 1914, **20**, 187—188.

METALLIC strontium in the form of rods can be prepare by the electrolytic method at a sufficiently low temperature. A mixture of 84·1 per cent. of strontium chlorid and 15·9 of potassium chloride is a suitable electrolyt and the metal can readily be obtained with current yield up to 80 per cent., if the temperature is not allowed t rise much above the m. pt. of the bath (628° C.)—W. H

Metals; The hardness of ——. J. H. Andrew. Int. Zeits. Metallog., 1914, **6**, 30—31.

The hardness of iron-carbon alloys is discussed. Hardness of a quenched steel is considered dependent upon the transformation of the true austenitic solution into martensite, which constituent may be regarded as being composed of finely divided cementite embedded in a matrix of partially undecomposed solid solution along with a small amount of α-iron, the extreme hardness of martensite being due to the exceedingly hard carbide molecules embedded in a relatively hard matrix.—T. St.

Lime and magnesia; Determination of —— in ores and slags. L. Blum. Stahl u. Eisen, 1914, **34**, 487—491.

In the determination of lime and magnesia in ores and slags a single precipitation with ammonia for the removal of iron, alumina, manganese, and phosphoric acid gives low results through co-precipitation of lime and magnesia. Double precipitation gives a precipitate free from alkaline earths, but the results are low because of the solubility of calcium oxalate and magnesium ammonium phosphate in strong ammonium chloride solutions. The basic acetate separation is recommended as being both rapid and exact; manganese is removed together with iron, etc., by addition of bromine water previous to boiling. Magnesia may be precipitated either hot or cold; sodium phosphate is preferable to sodium ammonium phosphate, as the precipitate produced by the latter consists of minute crystals difficult to filter.—W. R. S.

Determination of titanium as phosphate. Jamieson and Wrenshall. *See* XXIII.

Patents.

Sulphur from pyritic ores; Process for the recovery of —— W. A. Hall, New York. Eng. Pat. 26,370, Nov. 16, 1912.

A reducing gas, such as water- or producer-gas, is introduced into the upper level of a water-jacketed, pyrites-smelting furnace, whereby oxidation of sulphur vapour is prevented, and sulphur dioxide is reduced to sulphur. The products of the reaction, carrying sulphur in suspension, are passed through separating devices, such as gas-washers of the Thiesen type (see also following abstract).—O. R.

Sulphur; Process for the collection and separation of finely divided ——. W. A. Hall, New York. Eng. Pat. 26,594, Nov. 19, 1912.

Sulphur vapours and gases, containing hydrogen sulphide and sulphur dioxide (see preceding abstract), are agitated with a considerable volume of water. This may be effected by drawing water and the gases in question into the body of a centrifugal pump, or by means of an arrangement of vacuum pans containing water, through which the fumes from the furnace are caused to penetrate.—O. R.

Alkali or alkaline earth metals; Method of producing ——. J. E. Bucher, Providence, R.I., U.S.A. Eng. Pat. 139, Jan. 2, 1913.

See Fr. Pat. 453,086 of 1913; this J., 1913, 736. In place of the cyanides, other cyanogen compounds of alkali or alkaline-earth metals may be used, such as ferrocyanides or ferricyanides.—T. F. B.

Sodium and other alkali metals; Electrolytic process and apparatus for the manufacture of ——. E. Marguet. Eng. Pat. 11,278, May 14, 1913. Under Int. Conv., April 9, 1913.

Commercial caustic soda is employed, and the external walls of the electrolytic vessel are surrounded by a cold air chamber or coils for circulating water, with or without a bad heat conducting material between the cooling device and the walls of the vessel. The cathodes, of any suitable metal, are placed near the walls in the coolest part of the fused electrolyte, and are constantly covered by a crust consisting of impurities of the electrolyte together with the alkali metal. The thickness of the protective coating on the cathodes may be regulated by allowing the temperature of the electrolyte to rise, so as to break up the surface of the coating to a suitable extent. The anode, of iron or steel, is of large surface conforming to the shape of the electrolytic vessel, and the electrolyte is charged into the central part of the anode where the liquid is hottest. The sodium is removed from a collector near the walls of the vessel, without removing either cover, cathodes or anode.—B. N.

Magnetic separators. F. Krupp A.-G. Grusonwerk Magdeburg-Buckau, Germany. Eng. Pat. 14,426, June 21, 1913. Under Int. Conv., July 19, 1912.

The material travels across the magnetic field in the same direction, relatively to the co-operating magnet pole, as the surface to which the magnetisable particles are attracted. The magnetic field is divided into partial fields, of different strengths, and the gap and width in any one of these is adjustable independently of the others, by dividing the magnet pole or poles of the separator into lamellæ, which are individually adjustable and situated parallel to the direction of travel of the material, or by forming one or each magnet pole of the separator of interchangeable pole pieces, arranged side by side parallel to the feed of the material. Or, the subdivision of the fields may be effected by stepping the rotatable cylindrical armature to which the magnetic material is attracted, this formation being adopted in conjunction or not with a stepped formation of one or each of the magnet poles with which the armature co-operates.—B. N.

Copper from ores; Electrolytic process for extracting ——. N. V. Hybinette. Eng. Pat. 22,745, Oct. 8, 1913.

The ore, containing the copper partly as oxide and partly as sulphide, is leached with an acid sulphate solution containing a large quantity of iron, of which only a small portion is in the ferric state. The resulting solution is electrolysed in cells without diaphragms, the operation being interrupted before sufficient iron is oxidised to interfere with the plating, and the solution returned to the leaching tank, where the ferric salts are again reduced. After continuous leaching and electrolysis, the copper left in the ore is removed by the use of a portion of the same solution containing a larger quantity of ferric sulphate, the oxidation of the latter being effected by the use of an electrolytic cell with diaphragm.—B. N.

Copper; Hydrometallurgy of ——. E. R. Weidlein, Pittsburgh, Pa., Assignor to Metals Research Co., New York. U.S. Pat. 1,089,096, March 3, 1914.

Ores, roasted matte, or other copper-bearing materials are leached so as to obtain a solution containing not more than 1 per cent. of free sulphuric acid and not more than 3 per cent. (preferably about 1·5 per cent.) Cu. The solution is neutralised, and the copper precipitated almost quantitatively by heating with sulphur dioxide under pressure. After separating the precipitated copper, the residual liquor is used to extract a further quantity of copper from the ore, etc., and the sequence of operations repeated until the ore is exhausted, the last extracting liquor being washed out by a further quantity of residual leach liquor.—A. S.

Metallurgical and other furnaces. A. Williams, Brymbo, Wales. Eng. Pat. 26,218, Nov. 15, 1913.

To render the port end of a fixed or tilting furnace more easily accessible for cleaning or repairs, it is mounted upon a frame which in turn is mounted on a sub-frame. The main frame can be rotated about a vertical axis or an axis inclined to the vertical, and the sub-frame can be moved longitudinally away from the furnace.—A. S.

Furnaces; Ore roasting ——. E. Bracq, Lens, France. Eng. Pat. 26,736, Nov. 20, 1913. Under Int. Conv., Nov. 21, 1912.

In a roasting furnace with a helical hearth, the bricks composing the hearth are tapered in horizontal and vertical cross-section, and are provided at the edges with means for keying to each other. They are disposed in the hearth with "concentrically staggered joints."—T. St.

Converter. J. V. Bretaud, Highland Park, Mich. U.S. Pat. 1,088,401, Feb. 24, 1914.

The converter consists of an upper and a lower section, with a thin layer of refractory material between the adjacent ends, which are held in engagement with the refractory material in an annular pivoted supporting ring. An air-box constructed in two parts meeting in a vertical plane, has one part fixed to the pivoted supporting ring, and the other fixed to the lower section of the converter, and means are provided for forcing the two parts into contact so as to form an air-tight joint.—A. S.

Metallurgical furnaces; Electrical heating device for ——. U. Wedge, Ardmore, Pa. U.S. Pat. 1,088,496, Feb. 24, 1914.

The furnace comprises a series of superposed working chambers and a central rotating shaft, with an electrical resistance body mounted thereon. Electrical resistance bodies are also suspended by loops embedded in the roofs of the chambers, so as to radiate heat downwards upon the material on the hearths of the chambers, whilst the material itself is agitated by rabbles carried by the shaft. —B. N.

Mineral and metallic substances which are to be united by pressure; Process of preliminarily treating —— A. R nay, Berlin, Assignor to General Briquetting Co., New York. U.S. Pat. 1,087,183, Feb. 17, 1914.

Immediately before the loose particles are compressed, and before they are introduced into the briquetting press, they are treated with steam containing a hydrocarbon, so that the particles still contain steam, when the press is closed.—T. St.

Tin; Method of recovering ——. W. Hoskins, Chicago, Ill. U.S. Pat. 1,088,422, Feb. 24, 1914.

A bed of carbon is kept incandescent by introducing air at different levels and in progressively decreasing quantities in the downward direction, and the mixture of tin, or tin alloys, and their oxides is fed on to the top of the bed, whereby the oxides are reduced and the metal melted. The molten metal percolates downwards through zones of progressively lower temperature, and is discharged at the base of the bed of carbon.—A. S.

Centrifugal filtering or dewatering machine for ore-pulp. J. C. King, Assignor to A. Wilkins, La Junta, Colo. U.S. Pat. 1,088,823, March 3, 1914

Filtering screens are mounted on the outer edge of a rotary table and are normally stationary with respect thereto. The ore pulp is fed on to the screens and at intervals these are lifted bodily in a plane parallel to the axis of the table and at the same time turned to a position at right angles thereto, whereby slime deposited on the screens is discharged by centrifugal force.—A. S.

Sintering ores; Apparatus for ——. A. F. Plock, Pittsburgh, Pa., Assignor to Pittsburgh Metallurgical Co., Inc., Wilmington, Del. U.S. Pat. 1,089,153, March 3, 1914.

The apparatus comprises a series of cars for holding the ore, each with a false bottom in the form of a grating; the chamber below the grating has a restricted opening communicating with an exhaust pipe leading to a suction fan. The cars are supported on a track beneath an igniting hood, and lateral transfer tracks are provided whereby each car may be independently removed from the series. —A. S.

Ores; Process and apparatus for reducing ——. A. Niewerth. Fr. Pat. 463,230, Sept. 27, 1913. Under Int. Conv., Aug. 21, 1913.

See U.S. Pat. 1,081,287 of 1913; this J., 1914, 87. A current of air is pumped through one of the auxiliary shafts into the central shaft, where a reducing gas is formed to reduce the ore. The gas then passes into the second auxiliary shaft, where it is regenerated by the carbon. By reversing the pump, the gas is again brought to the ore charge in the central shaft, and the process is continued to the desired extent.—T. F. B.

Tungsten and molybdenum powder; Manufacture of heavy crystalline ——. H. Leiser. Ger. Pat. 270,194, Dec. 22, 1911.

A tungsten or molybdenum compound, *e.g.*, tungstic acid (hydrate), is treated with ammonia solution, whereby a relatively dense product, *e.g.*, $(NH_4)_2W_3O_{12}$, is obtained. This is heated first to a temperature at which liberation of the ammonia and slight reduction take place, and then at 1100°—1200° C. in presence of hydrogen, whereby transformation of the reduced amorphous metal into a coarse crystalline powder is effected.—A. S.

Zinc blende and other sulphide ores; Mechanical furnace for roasting —— and for treating chemical compounds with compressed air or other gases. R. Kessler. Ger. Pat. 270,273, Feb. 14, 1913.

A crucible furnace in which, during the blowing, the ore is agitated by a rotating screw, which is alternately raised and lowered.—A. S.

Steel; Process for the manufacture of —— and apparatus therefor. Rombacher Hüttenwerke, and J. I. Bronn, Rombach, Germany. Eng. Pat. 29,051, Dec. 17, 1912.

See Fr. Pat. 455,399 of 1912; this J., 1913, 947.—T. F. B.

Steel; Making or refining ——. E. Humbert, Barleduc, France. Eng. Pat. 18,116, Aug. 8, 1913.

See Fr. Pat. 461,459 of 1913; this J., 1914, 204.—T. F. B.

Metallurgical and chemical process [decarburising iron, etc.]. J. E. Bucher, Coventry, R.I., Assignor to Nitrogen Products Co. U.S. Pat. 1,087,900, Feb. 17, 1914.

See Fr. Pat. 459,853 of 1913; this J., 1913, 1159.—T. F. B.

Iron and steel; Process and high-pressure furnace for the direct production of ——. C. Otto, Dresden, Germany. U.S. Pat. 1,089,951, March 10, 1914.

See Fr. Pat. 435,854 of 1911; this J., 1912, 393.—T. F. B.

Zinc ores; Plant for the recovery of zinc from ——. A. Roitzheim, Duisberg-Ruhrort, Germany. Eng. Pat. 6771, March 19, 1913. Under Int. Conv., April 10, 1912.

See Fr. Pat. 455,726 of 1913; this J., 1913, 949.—T. F. B.

Zinc-lead ores; Treatment of refractory ——. P. C. C. Isherwood, Bushey Heath. U.S. Pat. 1,089,412, March 10, 1914.

See Eng. Pat. 22,855 of 1912; this J., 1913, 1073.—T. F. B.

Zinc; Process for separating —— from crude materials containing zinc by blowing. F. C. W. Timm. Fr. Pat. 463,330, Oct. 7, 1913. Under Int. Conv., Oct. 8, 1912.

See Ger. Pat. 268,427 of 1912; this J., 1914, 143.—T. F. B.

Ores; Process of dressing —— by means of gas. K. Takeda, Tokyo. Eng. Pat. 7272, March 27, 1913.

See Fr. Pat. 455,430 of 1913; this J., 1913, 949.—T. F. B.

Ore-dressing apparatus. H. Velten, Milan, Italy. U.S. Pat. 1,089,606, March 10, 1914.

See Eng. Pat. 502 of 1913; this J., 1913, 540.—T. F. B.

Cupola furnaces; Method of and means for preventing the formation of carbon monoxide in ——. E. Schürmann, Dresden, Germany. Eng. Pat. 11,073, May 10, 1913.

See Fr. Pat. 458,242 of 1913; this J., 1913, 1071.—T. F. B.

Metal furnace. I. Hall, Birmingham. Eng. Pat. 11,843, May 21, 1913.

See Fr. Pat. 462,568 of 1913; this J., 1914, 320.—T. F. B.

Melting-pot furnaces. V. Coppée, Paris. Eng. Pat. 14,726, June 25, 1913. Under Int. Conv., June 26, 1912.

See Fr. Pat. 456,803 of 1912; this J., 1913, 1074.—T. F. B.

Metals [copper]; Process for the electrolytic deposition of —— from solutions containing same. N. V. Hybinette, Christiania. Eng. Pat. 22,744, Oct. 8, 1913.

See U.S. Pat. 1,084,150 of 1914; this J., 1914, 205.—T. F. B.

Metals [copper]; Process for the electrodeposition of —— from solutions. N. V. Hybinette. Fr. Pat. 463,599, Oct. 14, 1913. Under Int. Conv., Nov. 4, 1912.

See U.S. Pat. 1,084,150 of 1914; this J., 1914, 205.—T. F. B.

Copper; Electrolytic process for extracting —— from ores. N. V. Hybinette. Fr. Pat. 463,598, Oct. 14, 1913. Under Int. Conv., Nov. 1, 1912.

See Eng. Pat. 22,745 of 1913; preceding.—T. F. B.

Metal; Extraction of ——. H. Pape, Oker in Harz, Germany. Eng. Pat. 24,847, Oct. 31, 1913.

See Addition of Sept. 23, 1913, to Fr. Pat. 449,480 of 1912; this J., 1914, 321.—T. F. B.

Ores; Apparatus for roasting and sintering ——. J. E. Greenawalt, Denver, Colo. U.S. Pat. 1,088,818, March 3, 1914.

See Eng. Pat. 10,249 of 1913; this J., 1903, 1116.—T. F. B.

Ore-bricks; Channel-furnace for burning ——. A. Ramén, Helsingborg, Sweden. U.S. Pat. 1,089,868, March 10, 1914.

See Eng. Pat. 20,240 of 1910; this J., 1911, 1147.—T. F. B.

Metallurgical method [production of refractory metals]. H. Kuzel, Baden, and E. Wedekind, Strassburg. Assignors to General Electric Co., New York. U.S. Pat. 1,088,909, March 3, 1914.

See Eng. Pat. 23,215 of 1909; this J., 1910, 1255.—T. F. B.

Tungsten manufacture. T. W. Frech, jun., Cleveland. Assignor to General Electric Co., New York. U.S. Pat. 1,089,757, March 10, 1914.

See Eng. Pat. 1915 of 1913; this J., 1914, 319.—T. F. B.

Magnetic separator. G. Ullrich, Assignor to F. Krupp A.-G. Grusonwerk, Magdeburg-Buckau, Germany. U.S. Pat. 1,089,993, March 10, 1914.

See Eng. Pat. 4595 of 1913; this J., 1913, 870.—T. F. B.

Furnace; Electric —— for melting ferromanganese, ferrosilicon, and other alloys. Ges. f. Elektrostahlanlagen m. b. H. Fr. Pat. 463,334, Oct. 7, 1913.

See Ger. Pat. 269,298 of 1912; this J., 1914, 319.—T. F. B.

Nickel; Recovery of —— from its ores. The Madagascar Minerals Synd., Ltd. Fr. Pat. 463,615, Dec. 21, 1912.

See Eng. Pat. 27,626 of 1912; this J., 1914, 30.—T. F. B.

Ores; Furnaces for roasting or drying ——. H. M. Ridge. Fr. Pat. 463,453, Oct. 6, 1913. Under Int. Conv., Oct. 17, 1912.

See Eng. Pat. 23,763 of 1912; this J., 1913, 1115.—T. F. B

Patents.

Electrodes for electric furnaces for the fixation of nitrogen. E. K. Scott, Bromley, Kent. Eng. Pats. 4723 and 4724, Feb. 24, 1913.

(1) Each electrode, of the horn type, comprises a tube divided lengthwise by a central plate into two compartments, through which air or a cooling medium may be passed. The inner end of the tube is closed by a sleeve, preferably made so that it may be rotated. The electrode may be perforated, so that a portion of the air or other cooling medium may be used for cooling the fixed gases. For forming the compartments, two D-shaped tubes may be arranged with their flat surfaces in contact, or two separate tubes may be used with metal cast round them. (2) An auxiliary electrode, composed of or containing magnetite, is employed, which projects into the gap between the horn-shaped electrodes for the purpose of striking the arc. The magnetite may be contained in a tube, or in the annular space formed by two concentric tubes, the air passing through the inner tube only, or through a tube surrounding the magnetite tube, or through both the inner and outer tubes.—B. N.

Furnaces; Regulating arc ——. E. K. Scott, Bromley, Kent. Eng. Pat. 4725, Feb. 24, 1913.

The furnace is supplied with three-phase alternating current; a transformer is employed with each phase, the primary winding being connected with the source of supply, and the secondary winding with the electrodes. The magnetic cores of the transformer are connected by yokes, so designed that, under abnormal conditions of load, considerable magnetic leakage takes place, or the secondary coil may be made movable for the same purpose. One of the limbs carrying the primary or secondary winding may be movable, to suit the requirements of any particular furnace. Various modes of joining up the primary and secondary coils are described.—B. N.

Furnace; Electric ——. C. C. Whitmore, Assignor to W. B. Carroll, Butte, Mont. U.S. Pat. 1,089,300, March 3, 1914.

The furnace body is provided at its ends with slots, and electrodes of tubular form, to which a cooling fluid is supplied, extend through the body approximately parallel to each other. One of the electrodes passes through the slots, and is adjustable by suitable mechanism with respect to the first electrode, so that it may be tilted at different angles.—B. N.

Electrode; Storage-battery —— and process of making same. H. C. Hubbell, Newark, N.J. U.S. Pats. 1,087,236 and 1,087,237, Feb. 17, 1914.

(1) The electrode comprises a plate consisting of thin parallel strips of a metal electronegative to cadmium in an alkaline electrolyte, the strips being disposed face to face edgewise to the plate, and separated by layers of cadmium oxide. Cadmium strips may alternate with the electronegative metal, the cadmium layers being oxidised by heating the plate in the presence of oxygen to a temperature below the melting point of cadmium. (2)

Alternate layers of cobalt, nickel, and a metal having a solubility similar to copper are arranged in the order, copper-like metal, cobalt, nickel, cobalt, and copper-like metal. The copper layers are dissolved by using the plate as anode in a solution containing sodium and ammonium acetates and free ammonia, at a current density which leaves the cobalt unattacked, then oxidising the latter by employing the plate as anode in a dilute solution of phenol and fixed alkali, using a "forming" current of low density.—B. N.

Electrolytic generator [*for hydrogen and oxygen*]. C. Ellis, Montclair, N.J. U.S. Pat. 1,087,937, Feb. 24, 1914.

The apparatus, for generating hydrogen and oxygen, comprises a rectangular receptacle having T-shaped projections on its inner walls, with a cover from which hangs an anode, consisting of a plate having T-shaped projections disposed symmetrically along its surface and parallel to the T-shaped projections of the cathode wall. A gutter is disposed along the sides of the generator for the removal of spray. The cathode surface is 50 per cent. greater in area than the anode surface, and the cathode compartment is maintained under a pressure higher than that of the anode compartment, whereby hydrogen practically free from oxygen is obtained.—B. N.

Carbon electrode having protective covering, and process for producing same. C. H. Schroers, Assignor to Ges. f. Teerverwertung m. b. H., Duisburg-Meiderich. Germany. U.S. Pat. 1,088,734, March 3, 1914.

See Fr. Pat. 454,475 of 1913; this J., 1913, 874.—T.F.B.

Manufacture of metallic oxides or compounds [*hydroxides, by electrolysis*]. Eng. Pat. 4082. *See* VII.

Manufacture of a material suitable for electrical insulation and other purposes. Eng Pat. 8117. *See* XIII.

XII.—FATS; OILS; WAXES.

Japanese sardine oil; Highly unsaturated fatty acids of ——. R. Majima and T. Okada. Science Reports, Tôhoku Imp. Univ., Japan, 1914, 3, 1—18.

The unpleasant odour of Japanese sardine oil can be removed by dissolving the oil in petroleum spirit and shaking the solution with potassium hydroxide solution below 10° C. Saponification of the oil is readily effected cold. On bromination of the fatty acids, preferably in ethereal solution, a mixture of bromides, composition almost agreeing with the formula, $C_{18}H_{28}O_2Br_8$, was obtained, but this when freed from bromine by heating with zinc dust and acetic acid, left fatty acids with too high mol. weight (338) and iodine value (380) for the formula. $C_{18}H_{28}O_2$. Acetone effected only partial fractionation of the bromo-fatty acids. The saturated fatty acids obtained by the catalytic hydrogenation of the unsaturated acids had mol. weight 349 and m. pt. 75° C., and consisted in the main of higher homologues of stearic acid such as $C_{20}H_{40}O_2$ or $C_{22}H_{44}O_2$. Similar results were obtained on hydrogenating the more fluid fatty acids of the oil after separation of the less fluid acids by chilling with salt and ice and then with solid carbon dioxide and ether. Polymerisation prevented fractionation of the unsaturated acids by distillation as methyl esters. They yielded, on oxidation, a decahydroxybehenic acid, $C_{22}H_{34}O_2(OH)_{10}$ (m. pt. 215° to 218° C.), and two isomeric dihydroxypalmitic acids (m. pts. 125° and 112°—114° C.), but no tetrahydroxy- or hexahydroxystearic acid.—C. A. M.

Vegetable oils; Action of diazo-derivatives upon ——. P. Sisley and Frehso. Bull. Soc. Chim., 1914, **15**, 295—298.

Certain fatty oils appear to contain constituents which react with diazonium compounds to give red or reddish brown colourations. A solution of diazoparanitrobenzene chloride was found to give the most satisfactory results, the oil being shaken with a few drops of this reagent and half its volume of 20 per cent. sodium acetate solution. Pure olive oil gave a negative result, but arachis and sesamé oils gave red colourations, and could be detected when present to the extent of 10 per cent. in olive oil. Cottonseed, castor, walnut and linseed oils also gave reddish colourations, but not sufficiently characteristic individually to differentiate between them.—G. F. M.

Nickel in fats; Detection of ——. R. H. Kerr. J. Ind. Eng. Chem., 1914, **6**, 207.

In testing products containing hydrogenated cottonseed oil for nickel by Bömer's method (this J., 1912, 996), after the addition of dimethylglyoxime and ammonia a red colour sometimes appears which closely resembles that produced when a trace of nickel is present, except that it is fugitive, fading away almost entirely in a few minutes. It appears to be due to an organic base extracted from the oil by hot hydrochloric acid, for it is never produced, in absence of nickel, if the acid extract prepared in the usual way be evaporated and the residue heated with 2—3 c.c. of nitric acid to destroy organic matter, before applying the dimethylglyoxime test.—A. S.

Carnauba wax. C. Lüdecke. Seifensieder-Zeit., 1913, **40**, 1237—1238, 1274—1275, 1302—1303, 1327—1328. Chem. Zentr., 1914, **1**, 1031—1032.

The melting point of crude carnauba wax is above 83° C. (solidif. pt. 80° C.) and increases with the age of the sample up to over 86° C., but not up to or over 90° C. as is frequently stated in the literature: lighter specimens have a somewhat lower melting point than those of darker colour. For the determination of the acid and saponification values the author uses a method somewhat similar to that of Berg (this J., 1909, 991) and of Bohrisch and Kürschner (compare this J., 1906, 701). The chief characters of carnauba wax and of the most frequently used adulterants are shown in the following table:—

	Carnauba wax.	Montan wax.	Candelilla wax.	Rosin.	Japan wax.	Stearic acid.
Specific gravity	0·992	0·920—0·970	0·970	—	0·960—0·975	—
Acid value	6—10	22—36	13—18	146—180	19—24	195—200
Saponif. value	70—86	60—84	50—60	168—195	214—224	195—200
Ratio number	7·6—10·7	1·3—1·7	2·3—2·8	0·08—0·15	8·3—10	—

For the determination of unsaponifiable matter, 5 grms. of the wax are mixed with 2 grms. of olein (the unsaponifiable matter of which has been determined or removed) and saponified by heating with 5 grms. of caustic soda, 10 grms. of water, and 30 grms. of alcohol for 2—3 hours under a reflux condenser. The mixture is then evaporated and, after addition of 2 grms. of sodium bicarbonate and 20 grms. of ignited sand, dried till of constant weight. The powdered residue is extracted in a Soxhlet apparatus with petroleum ether, the extract evaporated, and the residue weighed. If it amount to more than 55 per cent., the excess over this quantity may be regarded as paraffin or ceresin, according to the melting point.—A. S.

Soluble silicates in soaps; Sodium chloride as a reagent for the detection of ——. E. Isnard. Ann. Chim. Analyt., 1914, 19, 98—100.

The precipitation of silicic acid by ammonium chloride is rendered more complete if sodium chloride is presen in the solution. Sodium chloride alone may be used as a precipitant of silicic acid if the solution be brought to saturation by adding the dry salt. The precipitate thus obtained contains no alumina which may be present in the solution, as is the case if precipitation is effected by means of ammonium chloride. In the case of soaps, after separating the fatty acids, the acid solution is neutralised with sodium carbonate, and saturated with sodium chloride.—J. A.

Washing powders containing perborate and their analysis. R. Jungkunz. Seifensiederzeit., 1914, 41, 4—6, 26—27. Chem. Zentr., 1914, 1, 1033.

The content of active oxygen in perborate washing powders is usually calculated to $NaBO_3$, but this may lead to erroneous results, as commercial sodium perborate does not always correspond to the formula $NaBO_3,4H_2O$; a determination of the boron should therefore also be carried out. 15—20 grms. of the powder are treated with hydrochloric acid (3 : 1) in presence of methyl orange until a red colour is produced, and after separating the fatty acids, 100 c.c. of alcohol are added, and the solution agitated for 1 hour, weighed and filtered. 50 c.c. of the filtrate are diluted to 100 c.c. with water in a tared flask, shaken with 0·5—1 grm of kieselguhr, filtered, and the boric acid determined in 20 c.c. of the filtrate, after neutralisation with $N/4$ caustic soda, by titration in presence of 1·5—2 grms. of mannitol. The solution should be free from carbon dioxide and phosphates.—A. S.

Determination of rosin in varnishes, oils and soaps. Wolff and Scholze. *See* XIII.

Erratum.

This J., March 31, 1914, p. 323, col. 1, line 27 from bottom, *for* "lard stearodipalmitin" *read* "butter stearodipalmitin."

Patents.

Glycerin; Process of distilling ——. F. J. Wood, Assignor to Marx and Rawolle, New York. U.S. Pat. 1,089,383, March 3, 1914.

The apparatus comprises a number of stills with their respective condensers arranged in series. After distilling off water, the substantially anhydrous glycerin is introduced into the first still and a portion is distilled off and condensed, the remainder being transferred to the second still and another portion distilled and condensed, and so on. Distillation and condensation are effected by a single current of steam led through the stills and condensers in succession, the glycerin at each still being combined with the steam from which the glycerin vapours of a preceding distillation have been condensed.—A. S.

Glycerin: Decolourising ——. F. Lindner, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,089,775, March 10, 1914.

See Eng. Pat. 16,260 of 1909; this J., 1910, 768.—T. F. B.

Fats and oils; Bleaching ——. F. Müller, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,089,253, March 3, 1914.

See Fr. Pat. 431,294 of 1911; this J., 1911, 1396.—T. F. B.

Sulphonated oils or fats: Process for making ——. Stolle und Kopke, and R. Russ. Fr. Pat. 463,312, Oct. 6, 1913.

See U.S. Pat. 1,081,775 of 1913; this J., 1914, 91.—T. F. B.

Hydrogenated [fat] product. U.S. Pat. 1,087,161. *See* XIXa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

White lead; Constitution of ——. E. Euston. J. Ind. Eng. Chem., 1914, 6, 202—203.

Experience in the production of white lead on the manufacturing scale by precipitation of a solution of basic lead acetate by carbon dioxide has shown that when precipitation is effected slowly under standard conditions, the precipitate first produced has the composition, $PbCO_3,Pb(OH)_2$, and is colloidal in character. On continuing the treatment the CO_2-content of the precipitate increases gradually and uniformly up to 16·6 per cent. ($PbCO_3$), and there are no indications of the formation of compounds of the composition, $2PbCO_3,Pb(OH)_2$ or $3PbCO_3,Pb(OH)_2$. The properties of the precipitate also change gradually and uniformly, except that the "apparent density" increases suddenly at a certain stage, probably owing to coagulation when the solution becomes acid. At no stage is the precipitate appreciably soluble in cane sugar solution; *i.e.*, it does not contain uncombined lead hydroxide. Mixtures of $PbCO_3$ and $PbCO_3,Pb(OH)_2$ of the same composition as samples of white lead had the same characters in regard to the amount of linseed oil required to form a paste, ease of miscibility with linseed oil, and opacity and spreading power when mixed as a paint. It is concluded that white lead made by the precipitation process is a mixture of amorphous $PbCO_3$ and $PbCO_3,Pb(OH)_2$, whilst white lead made by the stack (Dutch) process may also contain crystalline $PbCO_3$ and occasionally $Pb(OH)_2$.—A. S.

Rinman's green. A. Hedvall. Z. anorg Chem., 1914, **86**, 201—224. (See this J., 1913, 982.)

Rinman's green is a solid solution of zinc oxide in cobalt oxide, which usually crystallises (like zinc oxide) in the hexagonal system. It is not possible to separate zinc oxide from cobalt oxide by digestion with ammonium carbonate solution, as cobalt always goes into solution to an appreciable extent.—W. H. P.

Paints; Toxic and antiseptic properties of ——. H. A. Gardner. Oil and Colour Trades J., 1914, 45, 1000—1006.

Water which had been exposed for 1 week in the "scrim" room of a linoleum factory contained appreciable quantities of formic, acetic, and butyric acids and also aldehydes. The author has shown previously (this J., 1914, 266) that the vapours evolved from drying oil paints contain small quantities of carbon monoxide, and the change in the blood corpuscles of a person who has breathed such vapours in an unventilated room is probably due to carbon monoxide rather than to turpentine (compare Armstrong and Klein, this J., 1913, 320); the turpentine appears to stimulate the production of carbon monoxide. The vapours from drying oil paints act as an efficient antiseptic. Of the volatile products used as paint thinners, *e.g.*, oil of turpentine, benzol, benzine (b. pt. 68° C.), benzol containing 5 per cent. of nitrobenzene, high-boiling petroluem spirit (flash point in open cup 39° C., b. pt. 160° C.), benzol is stated to be most, and high-boiling petroluem spirit least dangerous.—A. S.

Rosin; Determination of —— in varnishes, oils and soaps. H. Wolff and E. Scholze. Chem.-Zeit., 1914, **38**, 369—372, 382—383.

Fahrion's modification of the Twitchell method for the determination of rosin (this J., 1911, 1266) is subject to an error due to the solubility in water of oxyabietic acid, a constituent of all rosins, and the process of esterification is both long and incomplete. In the following method these difficulties are avoided. 2—5 grms. of the mixed rosin and fatty acids are dissolved in 10—20 c.c. of absolute methyl alcohol and esterified by boiling for 2 mins. under a reflux condenser with 5—10 c.c. of a solution of 1 part of sulphuric acid in 4 parts of methyl alcohol. The esterified mixture is treated with five to ten times its volume of a 7—10 per cent. solution of salt, in which oxyabietic acid is insoluble, and the fatty acid esters and free rosin acids are extracted with ether or a mixture of ether and petroleum spirit. The salt solution is drawn off and re-extracted once or twice with fresh solvent. The extracts are then washed with salt solution until the washings have a neutral reaction. After addition of alcohol, the ethereal extract is titrated with $N/2$ alcoholic potash and the percentage of rosin acids calculated on the assumption that they have an acid value of 160. The percentage thus found is reduced by 1·5, to allow for the fatty acids which escape esterification; or, after neutralisation of the rosin acids 1—2 c.c. excess of alcoholic potash may be added, the ethereal solution washed several times with water, the mixed washings and soap solution evaporated to small bulk, acidified, and after the addition of an equal volume of salt solution, extracted with ether. The ethereal extract is dried with anhydrous sodium sulphate and the ether evaporated. The residue is dissolved in 10 c.c. of absolute alcohol, re-esterified and extracted in the manner already described. The rosin acids thus obtained are free from fatty acids which have escaped esterification in the first treatment. The amount of rosin originally present in the mixture is obtained by multiplying the percentage of rosin acids by 1·07, there being, as an average, 7 per cent. of non-saponifiable matter in rosin.—J. A.

PATENTS.

Electrical insulation and other purposes; Manufacture of a material suitable for ——. The British Thomson-Houston Co., Ltd. From General Electric Co., Schenectady, N.Y. Eng. Pat. 8417, April 9, 1913.

THE resinous condensation product of a polyhydric alcohol and phthalic anhydride is prevented from hardening, whilst in the fused state, by dissolving in it 13 to 18 per cent. of naphthalene, anthracene, phenanthrene, etc. Cellular, fibrous or porous bodies may thus be impregnated with the fused mixture, the temperature being afterwards raised to vaporise the naphthalene and harden the resin. —B. N.

Oil varnish substitutes from animal oils; Process for the manufacture of ——. W. Kaempfe, Grossenhain, Saxony. Eng. Pat. 21,834, March 15, 1913. Addition to Eng. Pat. 15,012, June 27, 1912.

SEE Addition of April 1, 1913, to Fr. Pat. 445,565 of 1912; this J., 1913, 983. An alkaline-earth oxide, hydroxide, or carbonate may be used in place of the manganese sulphate.—T. F. B.

Pigments from titaniferous iron ores; Process of producing yellow ——. P. Farup, Trondhjem, Norway. U.S. Pat. 1,087,575, Feb. 17, 1914.

SEE Eng. Pat. 10,368 of 1911; this J., 1911, 1125.—T. F. B.

White lead; Process for the manufacture of ——. F. H. Sharpe, Lancaster. U.S. Pat. 1,088,460, Feb. 24, 1914.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber [synthetic]; Recent work on ——. A. Holt. Z. angew. Chem., 1914, 27, 153—158.

FOR the manufacture of isoprene, the lowest-boiling fraction of petroleum, of the composition, C_5H_{12}, may be used: by systematic chlorination, isomerisation, and liberation and addition of hydrochloric acid, the three hydrocarbons present (iso- and normal pentane and tetramethylmethane) can all be converted into isoprene (see Fr. Pats. 435,312 and 452,246; this J., 1912, 409; 1913, 672). Butadiene is best prepared from benzene or phenol. These are converted by hydrogenation into cyclohexane and cyclohexanol respectively. The latter is converted into tetrahydrobenzene by means of alumina at 230° C. and the former into the same product by chlorinating and then removing hydrochloric acid from the chlorocyclohexane by means of lime at 450° C. The tetrahydrobenzene is converted into butadiene and ethylene by heating to 500° C. in a quartz tube (see Fr. Pats. 441,203 and 441,619; this J., 1912, 843, 951). Polymerisation of isoprene or its homologues may be effected rapidly and quantitatively by means of sodium, but the product is not a true caoutchouc, either chemically according to the definition of Harries (this J., 1911, 1073), or in its physical properties. When isoprene is treated with sodium in an atmosphere of carbon dioxide (see Fr. Pat. 459,005; this J., 1913, 1164), the reaction is quite different from that which occurs with sodium in presence of air. There is no perceptible action at first, but finally the isoprene is converted completely into a black voluminous mass, which on treatment with water or alcohol yields a pure white caoutchouc, characterised by its indifference to solvents, in which it neither dissolves nor swells. Polymerisation of isoprene by heating in presence of small quantities of ozonides or peroxides (see Fr. Pat. 440,173; this J., 1912, 735) gives a larger yield of caoutchouc than heating without such addition, and the physical properties of the products are improved. Caoutchoucs obtained from isoprene by all of the methods mentioned can be vulcanised; that obtained by means of sodium in presence of air, however, only incompletely and with difficulty. The products obtained by means of sodium and carbon dioxide are somewhat easily oxidisable, this tendency increasing in the products from butadiene, isoprene, and methylisoprene (2.3-dimethylbutadiene-1.3), in the order given. Recent work (see Steimmig, this J., 1914, 267) indicates that all of the synthetic caoutchoucs yet obtained differ chemically from natural caoutchouc; whilst physically the vulcanised products from synthetic (isoprene) caoutchouc are equal in quality only to the products from medium-grade natural rubbers.—A. S.

Caoutchouc; Diacetylpropane (1.5-heptanedione) from ——. C. Harries. Ber., 1914, 47, 784—791.

IN a previous paper (this J., 1913, 983) it was stated that among the decomposition products of the ozonide of caoutchouc regenerated by means of pyridine from the halogen addition compound of Para caoutchouc, was 1.5-cyclo-octanedione. It has now been found that the ketone in question is really the hitherto unknown diacetylpropane, $CH_3.CO.(CH_2)_3.CO.CH_3$, mixed with a certain proportion of 1-methylcyclohexene-1-one-3,

$$CH_3.C \begin{matrix} \diagup\!\!\diagup CH.CO \diagdown \\ \diagdown CH_2.CH_2 \diagup \end{matrix} CH_2,$$

readily formed from it, by elimination of water, in presence of small quantities of alkali. The diacetylpropane could not be isolated in a pure condition but was identified by means of its dioxime (m. pt. 87° C.) obtained by treatment with hydroxylamine hydrochloride in neutral solution.—A. S.

Patents.

Caoutchouc substances; Process for modifying the properties of and improving synthetic —— and vulcanising the products obtained. Badische Anilin und Soda Fabrik. Fr. Pat. 463,137, Sept. 3, 1913. Under Int. Conv., Nov. 1 and Dec. 3, 1912, Jan. 27, March 19, and April 15, 1913.

See Eng. Pat. 975 of 1913; this J., 1914, 93. The substances may be treated with hot alkali hydroxides, alkali alkyloxides, or analogous substances, or with organic acids or their derivatives. The products may be vulcanised if necessary.—T. F. B.

Rubber: Process for preparing a product analogous to hard ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 268,947, Feb. 21, 1913. Addition to Ger. Pat. 266,618 (see Eng. Pat. 11,530 of 1913; this J., 1913, 1078).

The product of polymerisation of $\beta\gamma$-dimethylerythrene described by Kondakow, is vulcanised in presence of a relatively non-volatile aliphatic base or a derivative thereof, or of a non-volatile derivative of a volatile base (see also Ger. Pats. 267,945 and 268,387; this J., 1914, 93, 269). —T. F. B.

Vulcanisation of natural or artificial caoutchouc substances; Process for accelerating the ——. Farbenfabr vorm. F. Bayer und Co. Ger. Pat. 269,512, Feb. 26, 1913. Addition to Ger. Pat. 265,221 (see Eng. Pat. 11,530 of 1913; this J., 1913, 1078).

Any relatively non-volatile aliphatic base, or a derivative thereof, may be used in place of piperidine or its homologues or derivatives to accelerate vulcanisation (see also Ger. Pat. 266,619; this J., 1914, 94).—T. F. B.

Rubber waste; Process for regenerating vulcanised ——. H. Hutz. Ger. Pat. 268,843, Dec. 24, 1912.

Vulcanised rubber waste is treated with a chlorhydrin or with the intermediate product of the action of hydrochloric acid on glycerin. Hydrogen sulphide is evolved. —T. F. B.

Indiarubber: Manufacture of products from ——. H. Dogny, V. Henri, and E. Veil-Picard, Paris. U.S. Pat. 1,088,551, Feb. 24, 1914.

See Fr. Pat. 422,118 of 1910; this J., 1911, 561.—T. F. B.

Rubber: Process for making artificial ——. O. Röhm. Fr. Pat. 463,801. Dec. 26, 1912.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning extracts: Clarifying and decolourising ——. L. Pollak. Collegium. 1914, 129—130.

Edamin, a preparation from soya beans (compare Eng. Pat. 4597 of 1913; this J., 1913, 548), can be used in place of blood albumin for clarifying and decolourising tanning extracts. The substance is made into an emulsion with water, allowed to stand until slightly fermented and run into the tanning infusion at 45° C., the temperature being then increased to 60°—75° C. With Italian and Corsican chestnut and oak infusions, edamin has a decolourising power equal to blood albumin and a better decolourising power in the case of French chestnut infusions. Extracts decolourised with edamin contain as much lactic acid as blood-decolourised extracts.—T. C.

Sulphite-cellulose extract; Tanning with and detection of ——. W. Moeller. Collegium. 1914, 152—163.

Sulphite-cellulose extracts contain ligninsulphonic acids which are readily absorbed by hide substance and are very difficult to wash out. The sulphonic acids are the constituents which give the Proctor-Hirst reaction (this J., 1909, 293) and as they are so tenaciously retained sulphite-cellulose extract cannot be detected in aqueous extracts of leather tanned with it (see this J., 1913, 373). Cold 2 per cent. caustic soda solution extracts these sulphonic acids from such leather and on acidifying the solution gives the Proctor-Hirst reaction. Sulphite-cellulose extract which has been used to weight fully tanned leather is extracted by water alone. Hide tanned with a mixture of vegetable tanning material and sulphite-cellulose extract first absorbs the former and if sufficient is present to tan the hide fully, there is no absorption of the latter. (See also this J., 1913, 245, 616.)—T. C.

Leather; [Detection of] Free sulphuric acid in ——. J. Paessler. Collegium. 1914, 126—128.

When leather containing free sulphuric acid is immersed in pure water a proportion of the free acid, depending on the concentration of the acid in the leather, diffuses out. When the leather is placed in a dialyser the acid diffuses through the parchment membrane more rapidly than the other substances such as tannin and colouring matters which are also extracted by water, and can be detected by the usual methods in the diffusate. (See also this J., 1914, 95.)—T. C.

Patents.

Leather, hides, or skins; Treatment of —— with liquids. M. Loschkareff, Twer, Russia. Eng. Pat. 10,711. May 6, 1913.

The apparatus for treating hides or skins in tanning, dyeing, salt or other solutions, is provided with a spindle connected with a frame by three cross-stays arranged radially or tangentially to the spindle and forming an angle of 100° to 160° with each other; bars connecting the rim and the cross stays are arranged parallel or at a small angle to the cross-stays. The space is thus better utilised than with other devices and several bars of practically equal length may be used in each of the three groups. On the arm-cross or spider being turned, the supplementary angle between the main plane of the skins and the direction of rotation is greater and the action of the liquid during motion is thus better than in case of division into two or four.—D. J. L.

By-products of the animal kingdom: Method of treating solid —— of fibrous structure. A. H. Henderson. Assignor to The Henderson Rubber Co., Baltimore, Md. U.S. Pat. 1,087,904, Feb. 17, 1914.

The product in its natural condition is placed in a solution of salt in water combined with a mixture of water and glycerin, then immersed in a bath of heated oil which causes the natural moisture, surplus water and excess of glycerin absorbed to be expelled. The product is then separated into small particles, subjected to pressure in the presence of heat and vulcanising ingredients, immersed in a rubber solution and finally vulcanised.—D. J. L.

Leather: Cleaning goods made of washable ——. Karplus und Herzberger. Ger. Pat. 267,659, July 12, 1912.

In cleaning gloves, shoes, belts, etc., made of leather, substances capable of fixing the colour, *e.g.*, vegetable tannins, catechu, and gambier, are used along with the detergent. Dyestuffs capable of re-dyeing the leather, and substances, such as oil, glycerin, flour, or salt, which preserve the softness of the leather on drying, may also be added.—A. S.

Tanning. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng Pat. 7138, March 25, 1913.

See Fr. Pat. 462,635 of 1913; this J., 1914, 326.—T. F. B.

Tanning material. O. Schmidt and J. Müller, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,089,797, March 10, 1914.

See Fr. Pats. 451,875 and 451,876 of 1912; this J., 1913, 668.—T. F. B.

Glue; Process of manufacturing vegetable ——. F. Lehmann and J. Stocker, Berlin. U.S. Pat. 1,089,064, March 3, 1914.

See Fr. Pat. 408,240 of 1909; this J., 1910, 580.—T. F. B.

XVI.—SOILS; FERTILISERS.

Peat; Bacterial treatment of ——. W. B. Bottomley. J. Roy. Soc. Arts., 1914, 62, 373—380.

Analyses show the increase in the nitrogen content of soil to which "bacterised peat" (this J., 1913, 878, 919, 920) had been added. Experiments carried out at Kew, Chelsea Physic Garden, and Eton School Gardens, have shown its good effects on crops of various kinds. It has proved valuable as a top dressing for grass. Recent experiments indicate the remarkable effects of small quantities, and suggest that there is probably a factor analogous to that of the vitamines in animal growth and nutrition.—W. H. P.

Effects of the ensilage process on the solubility of "floats." Forbes and Fritz. *See* XIXA.

Patents.

Fertiliser [from fish-scrap]; Method of and apparatus for recovering the by-products in the manufacture of ——. S. C., Assignor to A. L. McGrath, Baltimore, Md. U.S. Pat. 1,087,031, Feb. 10, 1914.

The lighter constituents of the gases issuing from fish-drying furnaces are subjected to a preliminary acid treatment for the recovery of ammonia, the remaining gases are passed into a scrubber for the collection of solid matter, the scrubbed gases together with the gases issuing from the preliminary acid treatment are subjected to a second acid treatment, and the heat of the gases previous to scrubbing is utilised for drying the recovered solid matter. —O. R.

Phosphates; Process for obtaining —— *soluble in citric acid.* A. Hauck. Ger Pat. 270,329, Nov. 12, 1910.

Crude phosphates are fused at a temperature not below 2000° C. and treated with oxygen, air or other oxidising agent.—A. S.

Artificial manure [from leather waste]; Process for the production of an ——. A. Moise, Barr, Germany. Eng. Pat. 12,800, June 2, 1913.

See Fr. Pat. 458,674 of 1913; this J., 1913, 1079.—T. F. B.

XVII.—SUGARS; STARCHES; GUMS.

Sugar beet; Localisation of potash in the ——, *and its physiological significance.* A. Matousek. Z. Zuckerind. Böhm., 1914, 38, 235—251.

Investigation of the distribution of potash in the sugar beet throughout its period of growth, showed that in the seed potash was present in the cotyledons, the radicle, and the endosperm, but not in the perisperm; whilst in the plant it was present in every part, mostly in the leaf, less in the leaf stalk, and least in the root. In the root the amount increased towards the crown, and accumulated largely in injured parts. In water cultures with no potash in the nutrient liquid, the reserve already present in the seed migrated for the greater part to the portions of the plant exposed to light, most being found in the leaf. Etiolated leaves contained a remarkably small proportion of potash.—J. P. O.

Sugar in the beetroot; Formation and disappearance of ——. L. Cassel. Bull. Assoc. Chim. Sucr., 1914, 31, 563—576.

The theory of the formation of sugar by the leaves of the beetroot by the agency of chlorophyll being accepted, the quantity of green substance at the disposition of the plant, for the same variety at least, must have a real importance for the saccharine richness of the beetroot. Delay in sprouting is injurious in this respect, and a regular and uniform vegetation is eminently favourable.—L. J. de W.

Sucrose; Constants for use in the double polarisation (Clerget Herzfeld) method of determining ——. R. Gillet. Sucr. Belge, 1914, 42, 271—275.

In applying the Herzfeld formula:

$$\frac{D+I}{142{\cdot}66-0{\cdot}5t}$$

for calculating the percentage of sucrose by the double polarisation method, the factor 0·5 used for correcting the concentration constant when readings are made at different temperatures is correct only for very low temperatures, viz., 3°—7° C., and when readings are taken at 13°—26° C. the factor 0·49 should be applied.—J. P. O.

Water; Determination of —— *[by distillation] in massecuites and molasses.* W. Clacher. Intern. Sugar J., 1914, 16, 126—127.

Reliable results are obtainable in the case of cane sugar factory products by the distillation method of determining water (this J., 1913, 62). 50 grms. of the product, and 300 c.c. of paraffin oil boiling a little over 100° C., are distilled together until about 100 c.c. of oil and water, which are collected in a graduated cylinder, have passed over. Frequently, in the cane sugar factory the Brix hydrometer reading is taken as an indication of the total solids, but when sulphitation has been excessive this value is quite untrustworthy.—J. P. O.

Sugar group; Dissociation in the ——. *Part III.* J. U. Nef. Annalen, 1914, 403, 204—383.

Hexoses in alkaline solution are capable of breaking down in three different ways, involving the intermediate formation of 1.2-, 2.3- and 3.4-hexosedienols and the final production, respectively, of: formaldehyde and aldopentoses (8); diose and aldotetroses (4); and two mols. of *dl*-glyceric aldehyde. The last two processes have already been described (this J., 1910, 1264). As an example of the first process dextrose and *d*-galactose on oxidation in alkaline solution with air or hydrogen peroxide yield, respectively, *d*-arabonic and *d*-lyxonic acid. The same result is also achieved by the use of Fehling's solution. When the amount of alkali is reduced from 1 to 1/20 equivalent, the number of products is considerably lessened; dextrose yields a mixture of only six isomeric optically active hexoses, while *l*-arabinose yields only three pentoses. After the attainment of this equilibrium the relative amounts of the various sugars present is very different. As an example, a 30 per cent. aqueous solution of either dextrose, *d*-mannose or lævulose mixed with 1/20 equivalent of calcium hydroxide attained complete equilibrium in about three months. The solution then contained a certain amount of resin, considerable quantities of polysaccharides, and the following six hexoses, viz.—dextrose, *d*-mannose, lævulose, *d*-pseudofructose and α- and β-*d*-glutose. This result precludes the formation of any dienol beyond α-1.2-*d*-glucosedienol.

$CH_2OH.(CHOH)_3.C(OH):CHOH$ and 2.3-*d*-glucosedienol, $CH_2OH).CHOH)_2.C(OH):C(OH):C(OH).CH_2OH$. Aldoses may be separated from ketoses by treatment with bromine in 12 per cent. aqueous solution, whereby oxidation of the aldoses to aldonic acids is effected: ketoses are unaffected by this treatment. The method is thus applicable to the isolation of ketopentoses and -hexoses; an important group of natural products which are as yet only very imperfectly known. The mixture of sugars obtained as above from dextrose, etc., contained ketoses and aldoses in approximately equal amounts. The quantity of dextrose was about five times that of *d*-mannose: a result which the author attributes to the unsymmetrical addition of water to α-1.2-*d*-glucosedienol. The absence of *d*-allose and *d*-latose in the mixture denotes that these sugars cannot occur either naturally or in formose; in presence of a trace of alkali or of suitable enzymes a non-reversible change to a mixture of the six sugars mentioned above would take place. Similar considerations hold for other groups of sugars, *e.g.*, the six members of the *d*-galactose series are *d*-galactose, *d*-talose, *d*-tagatose, *l*-sorbose and α- and β-*d*-galtose with two corresponding *d*-galactosedienols. From these results the author concludes that synthetic formose can only contain 24 hexoses out of the 32 which are theoretically possible; further, the aldose forming about half of the mixture must be composed chiefly of *dl*-glucose and *dl*-galactose. In brief, in presence of small quantities of caustic alkali only certain sugars are capable of formation in natural or in ordinary synthetical processes: these may be arranged in 4 groups of 6 hexoses, 4 groups of 3 pentoses, and 2 groups of 3 tetroses. Very dilute alkaline solutions of dextrose, containing about 6 equivalents of alkali, when oxidised at 20° to 40° C. by means of air or hydrogen peroxide yielded a complex mixture of carbon dioxide, formic acid, glycollic acid, oxalic acid and *dl*-glyceric acid; also *d*-arabonic and *d*-ribonic acids; and *d*-erythronic and *l*-threonic acids. Cupric or mercuric oxide yielded these products and also *d*-gluconic and *d*-mannonic acids. From this it is evident that only the 6 hexoses mentioned above were present and that they are not oxidised by air or by hydrogen peroxide. In presence of amounts of alkali down to 1/30 equivalent, especially on warming, sugar solutions give rise to appreciable quantities of resin. Other reactions give rise, respectively, to polysaccharides and saccharinic acids; and these three changes being non-reversible tend to disturb the equilibrium. In all three cases, however, the change is exceedingly slow. The saccharinic acids are stated to be produced, by means of a reaction resembling the transformation of benzil to benzilic acid, from ortho-osones, —CH_2.CO.CO—, which are in turn produced from the salts of the original sugars. This osone formation is favoured by lead acetate or lead chloride; but all three processes take place to some extent in presence of small amounts of caustic alkali. The disturbances due to these reactions may be avoided by employing ½ equivalent of pure sodium carbonate solution in place of caustic alkali. Polysaccharides are always produced in presence of caustic alkali or amounts of sodium carbonate above ½ equivalent. It is remarkable, however, that pure potassium carbonate solution up to 3 equivalents effected no change in concentrated sugar solutions after keeping in closed vessels for 2 months. The two classes of polysaccharides are distinguished by the relative ease with which they react with dilute acids or Fehling's solution. Polymerisation to tris-oses, $(C_nH_{2n}O_n)_3$ or to α-bis-oses $(C_nH_{2n}O_n)_2$, is favoured by calcium acetate (from 1 to 3 equivalents), which is unable to effect enolisation or salt-formation. Excess of sodium carbonate solution, besides effecting these changes, brings about a condensation to polysaccharides of the nature of lactose and maltose. The tris-oses and α-bis-oses, *e.g.*, α-bis-*d*-glucose-*d*-fructose, $C_{12}H_{24}O_{12}$, hydrolyse with extreme ease; they only change into anhydro-α-bis-hexoses (disaccharides) and still further dehydrated products under the influence of caustic alkali. Thus, sucrose is among the products formed from the dextrose group of equilibrium isomerides in dilute alkaline solution. Novel structural formulæ are advanced by the author in order to illustrate the formation of such polymerisation and condensation products.—J. R.

Maple products; Analysis of ——. III. Range of variation of analytical values in genuine maple syrups. J. F. Snell and J. M. Scott. J. Ind. Eng. Chem., 1914, **6**, 216—222.

Experiments with 126 samples of genuine Canadian maple syrup showed that the values in which the differences between the maximum and minimum numbers were least were the conductivity value, the alkalinity of the soluble ash, the weight of the total ash, and the Winton lead number. Determinations of the values mentioned and of the refractometer reading and lead number determined by the Canadian method, are recommended for rapidly detecting adulteration. The limiting values for genuine maple syrups are shown in the following table:—

	Limiting values.

XVIII.—FERMENTATION INDUSTRIES.

Barley, malt and beer; Determination of the amino-acid- and polypeptide-nitrogen in —— by titration with acid after treatment with formaldehyde (formalin-titration). L. Adler. Z. ges. Brauw., 1914, **37**, 105—108, 117—121, and 129—133.

The method described is based on similar principles to that of Sörensen (this J., 1908, 135). Eighty c.c. of the wort, beer, or extract, in a 100 c.c. flask are heated in boiling water for 10 mins. to precipitate coagulable proteins, then cooled and treated with 1—2 grms. of barium chloride and 1 c.c. of a 0·5 per cent. solution of phenolphthalein in 50 per cent. alcohol. After the barium chloride has dissolved, the liquid is neutralised with a saturated solution of barium hydroxide, made up to 100 c.c. and filtered. Of the filtrate two portions, each

40 c.c. are rendered neutral ($p\text{H}=6\cdot8$; see Sörensen, this J., 1909, 950) by addition of acid until a drop of the liquid placed on sensitive azolitmin paper (Kahlbaum's) produces a neutral colour similar to that produced by a solution containing 1/30 grm.-mol. each of monopotassium phosphate and disodium phosphate per litre ($p\text{H}=6\cdot81$). The two solutions are next treated each with 10 c.c. of 35 per cent. formaldehyde solution neutralised shortly before use by adding, for every 10 c.c., 0·2 c.c. of the 0·5 per cent. phenolphthalein solution, and then $N/2$ sodium hydroxide until the liquid is faintly but distinctly red. As a blank test 10 c.c. of this formaldehyde solution are diluted with 45 c.c. of distilled water, treated if necessary with a 0·5 per cent. solution of Bismarck brown to adjust the tint to that of the actual solutions to be analysed, and titrated with $N/5$ barium hydroxide solution until a strong red colour is produced ($p\text{H}=9\cdot1$) not, however, so strong that further addition of alkali does not increase its intensity. The solutions to be analysed are titrated to the same tint. The concentration of the original wort or other liquid, should if possible be such that the volume of $N/5$ barium hydroxide required by each 40 c.c. portion, less the volume required by the blank test, amounts to about 20 c.c. This number multiplied by 2·8 gives the weight in mgrms. of amino-acid- or polypeptide-nitrogen in the 40 c.c. portion of the sample. The nitrogen of ammonium salts reacts with formaldehyde and is determined by this method. The method can be made to yield other useful values by carrying out the titration "in stages" as recommended by Henriques and Gjaldbaek (Z. physiol. Chem., 1910, **67**, 8—27 ; 1911, **75**, 363). For example, if the volume of $N/5$ barium hydroxide from which the nitrogen is calculated, as above, is designated "Stage II" and the volume required to bring the solution from the point of neutrality to litmus ($p\text{H}=6\cdot81$) to the first appearance of red colour with phenolphthalein ($p\text{H}=8\cdot3$) before addition of formaldehyde, is designated "Stage I," then the ratio Stage II/Stage I varies according to the nature of the nitrogenous compounds with which the formaldehyde reacts. For amino-acids the ratio usually lies between 6·8 and 11·5, whereas for polypeptides it is much lower, *e.g.*, for glycylglycine 2·1. The ratio cannot be determined very accurately in the case of coloured liquids such as malt extracts, and in all cases it should be interpreted with considerable reserve.

In a sample of barley 0·017 per cent and in a sample of malt 0·085 per cent. of amino-acid- and polypeptide nitrogen were found. To determine these values it was found necessary to prevent enzymic action during extraction, by first boiling the finely ground grain for two hours with alcohol. If the grain is extracted without this preliminary treatment, proteolysis occurs during extraction, even at 1° or 2° C., and the quantity of amino-acid and polypeptide-nitrogen may under favourable conditions be doubled or trebled. A pale beer was found to contain 174·9 mgrms. per litre, of nitrogen determinable by "formalin-titration."—J. H. L.

Maltase ; Influence of acids on the activity of dialysed ——. W. Kopaczewski. Comptes rend., 1914, **158**, 640—642.

In general, the optimum acidity for dialysed maltase (see this J., 1913, 441) is considerably lower than that for maltase which has not been dialysed, *e.g.*, $N/725$ instead of $N/170$ in the case of sulphuric acid. The optima found for different acids do not correspond to the same concentration of hydrogen ions, the values of $p\text{H}$ ranging from 2·80 to 6·97. The influence of acids on the activity of maltase cannot therefore be due entirely to the hydrogen ions, but the anions must play some part (cp. Bertrand and Rosenblatt, this J., 1913, 376).—J. H. L.

Maltase from beer yeast : Conditions of action of ——. *III.* L. Michaelis and P. Rona. Biochem. Zeits., 1914, **60**, 598.

A correction of a misprint in the article of which an abstract has already appeared (this J., 1914, 272), but which does not affect the abstract.

Enzymes ; Chemical composition and formation of ——. *XI.* H. Euler and K. G. Dernby. Z. physiol. Chem., 1914, **89**, 408—424.

Treatment of yeast for 48 hours in Lindner's nutrient sugar solution, which has previously been shown to augment the invertase activity of living yeast (see this J., 1912, 245, 654 ; 1913, 669 ; 1914, 97, 272), produced also a marked increase (about 36 per cent.) in the proteolytic activity, and a decrease in the fermentative power of the yeast. The effect on the proteolytic power was not dependent on the temperature at which the treatment was carried out (cp. this J., 1914, 272) nor was it influenced by the addition of sodium fluoride to, or the omission of phosphates from the nutrient solution (cp. Iwanoff, this J., 1905, 100). The presence of sodium fluoride (0·005 per cent.) appeared to retard the assimilation of ammonium salts by fermenting yeast. The proteolytic power of yeast was measured by first plasmolysing (liquefying) the yeast by digestion with glycerol for 3 hours, and then diluting with water containing chloroform and measuring the rate of dissolution of the yeast nitrogen at 37° C. It was found possible to determine nearly the whole of the dissolved non-coagulable nitrogen by "formalin-titration" (Jessen-Hansen's modification of Sörensen's method, see Abderhalden's *Handbuch der biochem. Arbeitsmethoden*, vol. 6, p. 270) so the latter method was employed in preference to Kjeldahl's. The duration of the preliminary plasmolysis did not affect the results, but it was necessary to dilute considerably with water afterwards, as high concentrations of glycerol inhibited proteolysis (cp. Gromow and Grigorieff, this J., 1904, 995). The rate of proteolysis was slightly accelerated by addition of potassium nitrate, potassium chlorate or hydrogen peroxide (cp. Gromow, *loc. cit.*) and slightly but distinctly retarded by addition of an extract of living yeast made with hot water, in consequence of the action of antiproteases (cp. Buchner and Haehn, this J., 1909, 899).—J. H. L.

Alcoholic fermentation ; Mechanism of ——. *III. Cell-free fermentation of polyhydroxycarboxylic acids.* A. v. Lebedeff. Ber., 1914, **47**, 660—672. (See also this J., 1911, 973 ; 1912, 1195.)

Glyceric acid is readily fermented by yeast maceration juice or by yeast dried by v. Lebedeff's method (this J., 1911, 147), carbon dioxide and acetaldehyde being produced. The quantity of carbon dioxide formed corresponds approximately with the equation, $CH_2OH.CHOH.COOH=CHC_3HO+CO_2+H_2O$, but the amount of acetaldehyde, even when allowance is made for its partial conversion into alcohol by the yeast enzymes, appears to be considerably below the calculated yield. Glyceric acid is fermented about three times as strongly as glyceraldehyde, and both optical forms are attacked. The decomposition of glyceraldehyde, which forms part of the scheme suggested by the author and Griaznoff (this J., 1912, 1195) to represent the mechanism of fermentation, was formerly assumed to be through the intermediate formation of methylglyoxal and pyruvic acid, but experiments on the fermentation of methylglyoxal have given only doubtful results, and the author now suggests that the glyceraldehyde is first converted into glyceric acid,

$$CH_2OH.CHOH.CHO+H_2O=CH_2OH.CHOH.CH(OH)_2$$
$$CH_2OH.CHOH.CH(OH)_2-H_2=CH_2OH.CHOH.COOH$$

which is then fermented. It has long been known that glyceric acid, when heated with potassium bisulphate produces pyruvic acid, and it appears likely in view o the fermentability of the latter (see Neuberg and others this J., 1911, 1179, 1465) that the enzymes of yeast juic decompose glyceric acid in the same way. The production of acetaldehyde from glyceric acid by enzyme throws light upon the real problem of fermentation, whicl is the conversion of the group $-CH_2OH$ into the methy group. Gluconic acid is also fermented by dried yeast but it is at present uncertain whether this is due to carboxylase or to "dehydratase." The carbon dioxid produced may possibly contain a small quantity c hydrogen, and no acetaldehyde appears to be forme Both glyceric and gluconic acids are fermented abo half as rapidly as pyruvic acid, but only in dilute solutions; at concentrations of 1 and 2 per cent. respectively they are not fermented at all, and they retard the autofermentation of the juice.—J. H. L.

[Brewing] water; New method for the determination of the salts of ——. W. Windisch, C. ten Doornkaat Koolman and H. Krumhaar. Woch. Brau., 1914, **31**, 65—67, 73—75, 85—87, 93—96.

The authors criticise the practice of coupling all the magnesia with carbonic acid, the remainder of the latter with lime, the remainder of this with sulphuric acid, and the remainder of the sulphuric acid and the chlorine with sodium. The following figures (parts per 100,000) relating to the samo brewing water before and after softening by treatment with lime, show the curious results obtained by applying this method to waters containing much magnesia:—

	$MgCO_3$	$CaCO_3$	$CaSO_4$	$MgSO_4$	Na_2SO_4	NaCl
Before softening ..	20·1	17·5	28·7	0·0	5·1	2·6
After softening ..	3·0	0·0	10·0	18·0	2·3	2·6

Experiments in which quantities of 100 c.c. of various "artificial" waters were treated with varying quantities of a standard solution of calcium hydroxide, boiled for 1 min., filtered and the filtrates and precipitates analysed, indicated that in the action of lime upon the salts of water a definite sequence is followed, viz.: (1) fixation of dissolved free carbon dioxide, (2) conversion of bicarbonates into normal carbonates and precipitation of calcium carbonate, (3) interaction with magnesium carbonate to form calcium carbonate and magnesium hydroxide, both of which are precipitated, and (4) interaction with magnesium sulphate or chloride to form soluble calcium sulphate or chloride and magnesium hydroxide which is precipitated. As the proportion of lime added to the water is increased, the calcium-content of the filtrates diminishes until phase (2) is complete, after which it remains constant throughout phase (3) and subsequently increases. The difference between the lime-content of the filtrates corresponding to phase (3) and the lime-content of the original water, plus the quantity of lime corresponding to the solubility of normal calcium carbonate (0·8 part CaO per 100,000), represents the amount of lime present as carbonate in the original water. For the determination of this value in practice, 100 c.c. of the water are boiled for 1 min. with such a volume of standard calcium hydroxide solution as will bring the reaction to phase (3); the liquid is afterwards filtered and the calcium-content of the filtrate determined. The quantity of calcium hydroxide solution required can be readily calculated from the amount of free carbon dioxide in the water (found by titration with $N/10$ sodium hydroxide in presence of phenolphthalein) and the amount of carbonic acid present as bicarbonates, found by titration with acid in presence of methyl orange (the authors found that magnesium carbonate as well as calcium carbonate is present in natural waters as bicarbonate). When the quantity of calcium carbonate present in the water has been determined as above, the remaining carbonic acid is allotted to magnesia, the lime and magnesia not accounted for as carbonates are coupled with sulphuric acid, and the remainder of the latter, together with the chlorine, is combined with sodium. The following figures (parts per 100,000) represent the results obtained by the old and new methods as applied to a water containing CaO, 17·4; MgO, 9·8; CO_2 as carbonate (determined by acid titration in presence of methyl orange), 16·3; SO_3, 15·2; free CO_2, 1·6 parts per 100,000:—

	$CaCO_3$	$MgCO_3$	$CaSO_4$	$MgSO_4$	NaCl
Old method....	12·5	20·6	25·6	0·0	2·6
New method ..	26·4	5·9	0·9	21·0	2·6

With waters containing very small quantities of magnesia the two methods give very similar results.—J. H. L.

Glycerol; Dehydration of ——, by a ferment occurring in water. E. Voisenet. Comptes rend., 1914, **158**, 734—736.

Water from diverse sources is capable of fermenting glycerol in the presence of appropriate nutrient material, which may be wholly mineral in character. Dehydration products of glycerol are thereby formed, the first of which, presumably 1.3-propanolal, changes rapidly to acrolein, which may be separated by fractional distillation. The optimum temperature is 25° to 30° C.—J. R.

Wines; The sulphuric acid content of German and other ——. C. A. Neufeld. Z. Unters. Nahr. Genussm., 1914, **27**, 299—311.

German wines are not plastered and do not contain more than 1·3 grm. of potassium sulphate per litre. A number of German red and white wines examined recently by the author contained, however, considerable quantities of sulphate, the amount present in the red wines (12 samples) varying from 2·12 to 3·98, and in the white wines (19 samples) from 2·01 to 4·54 grms. of potassium sulphate per litre; 11 French wines contained from 2·14 to 3·93 grms. per litre. The sulphuric acid was probably derived from the casks in which the wine had been stored, these having been treated with sulphurous acid and insufficiently washed before the wine was introduced. Such quantities of sulphuric acid influence the taste of the wine to a marked degree; in many countries a limit of 2 grms. of potassium sulphate per litre is fixed as the maximum quantity allowable in wines.—W. P. S.

Caramel [in wine, vinegar, brandy, etc.]; Detection of ——. D. Schenk. Apoth.-Zeit., 1914, **29**, 202—203. (See also this J., 1913, 376.)

When sugar is caramelised, hydroxymethylfurfural is produced which can give characteristic colour reactions with certain phenols dissolved in strong acids. Resorcinol in hydrochloric acid gives a cherry-red, β-naphthol in sulphuric acid a violet, and phenol in sulphuric acid an orange-yellow colouration. Colouring matters derived from coal tar do not react in the same way. The liquid to be tested, wine, vinegar, brandy, etc., is neutralised if acid, concentrated to a small bulk, extracted with ether, the ethereal extract treated with a few drops of a 5 per cent. solution of phenol in ether and allowed to evaporate. The residue is mixed with about 5 c.c. of sulphuric acid when the characteristic colour rapidly appears.—F. Shdn.

Distillation-residue of wine; Treatment of the ——. C. Matignon. Chem.-Zeit., 1914, **38**, 386—387.

The residues from the distillation of wine or of fermented molasses are rendered alkaline, and inoculated with a culture of the butyric acid ferment, after addition of aluminium sulphate, with a smaller proportion of aluminium phosphate and manganese and magnesium chlorides. Air is blown through the liquid for the first 6—10 hours, and the process is complete in about 3 days. Ammonia and trimethylamine, acetic, propionic, butyric, tartaric, malic, and citric acids and their potassium salts, glycerol, carbon dioxide, methane, and hydrogen are produced. The volatile bases and acids are recovered by distillation respectively before and after acidulation with sulphuric acid; the glycerol is distilled from the dried residue, which contains the dibasic acids and potassium salts. Ammonia and trimethylamine are separated by passing them as gases over a mixture of their sulphates; ammonium sulphate remains behind, and the trimethylamine is converted into cyanide by passing it through a tube heated to 1000° C. and absorbing the hydrocyanic acid formed in alkali. The volatile acids are dehydrated with aluminium sulphate and fractionated. These processes, which are due to Effront, have been in use for 3 years at Nesle, France. The conversion of the acetic and butyric acids, by catalysis with coke, into the corresponding ketones, for use in internal combustion engines, is contemplated.—O. E. M.

PATENTS.

Beer; Process of manufacturing ——. G. L. H. Seize. Fr. Pat. 464,080, Oct. 10, 1913.

MALT is steeped in about its own weight of water at 50° to 75° C. for from 5 to 15 hours, then crushed or ground, diluted with warm water (at about 75° C.) so that from 3 to 3·5 litres of water shall be present for each kilo. of malt, and when saccharification is complete, the wort is separated. Or, the mass, after being crushed, may be heated to boiling for about 10 minutes, and then treated with a suitable proportion of ground malt.—W. P. S.

Vinegar from milk; Manufacture of ——. F. Huberty et Cie. Fr. Pat. 463,266, Oct. 3, 1913.

PROTEINS are removed from milk serum by precipitation with tannin either before or after the addition of alcohol, or by concentrating the serum and adding alcohol. Or, the serum is distilled to dryness under reduced pressure, and the dry residue extracted with the distillate, leaving the proteins undissolved, and the solution treated with alcohol. The alcoholic solution is submitted to acetic fermentation. The resulting vinegar contains much of the lactose present originally in the serum.—W. P. S.

Acetifiers; Utilisation of the alcohol and acid vapours from —— *in the "rapid" vinegar process.* A. Mohr. Ger. Pat. 270,320, Feb. 15, 1913.

THE wort flows from the reservoir through a closed tube, wherein by an action similar to that of a water-pump, it creates a partial vacuum and draws in the alcohol and acid vapours from the acetifiers; the vapours are condensed by contact with the cold liquid. The wort flows into a receptacle, the air space of which is connected with a tube through which the vinegar from the acetifiers flows on its way to the storage vessel, so that any uncondensed vapours still present in the air are condensed in the latter.—A. S.

XIXA.—FOODS.

Salt-soluble proteins in wheat flour; Determination of the ——. G. A. Olson. J. Ind. Eng. Chem., 1914, 6, 211—214. (See also this J., 1913, 1124.)

GLIADIN was extracted from flour by both 1 per cent. and 10 per cent. solutions of sodium chloride; of the total protein extracted about 29 per cent. was gliadin with the 1 per cent. salt solution and 5 per cent. with the 10 per cent. solution. The following method is suggested for the determination of the salt-soluble proteins. 10 grms. of flour are digested with 500 c.c. of a 1 per cent. solution of sodium chloride, the mixture being shaken at intervals of 5 mins. for the first 2 hours and then allowed to stand overnight. After filtering, the total soluble nitrogen is determined in one 200 c.c. portion, and another similar portion is evaporated to dryness, the residue digested with 100 c.c. portions of 55 per cent. (by vol.) alcohol, the extracts filtered, and the filter washed with 55 per cent. alcohol: the nitrogen content of the precipitate is reckoned as albumin-nitrogen. The alcoholic solution is concentrated to 10 c.c., treated with 50 c.c. of distilled water, concentrated to 35 c.c., treated with 15 c.c. of water, allowed to cool, filtered, and the filter washed with cold water. The solution is precipitated with phosphotungstic acid, and the nitrogen content of the precipitate reckoned as globulin-nitrogen. The nitrogen-content of the filtrate is reckoned as amide-nitrogen, and the gliadin-nitrogen is obtained by subtracting the sum of the albumin-, globulin-, and amide-nitrogen from the total salt-soluble nitrogen. In all the nitrogen determinations, blank determinations are also made and the necessary corrections applied.—A. S.

Crude fibre; Determination of —— *in finely powdered substances.* J. Grossfeld. Z. Unters. Nahr. Genussm., 1914, 27, 333.

IN the determination of crude fibre in such substances as cocoa, flour, etc., by König's method, it is recommended that the filtration be carried out without the aid of the filter-pump. The glycerol-sulphuric acid mixture containing the crude fibre should be filtered through a Gooch crucible containing a layer of asbestos. If suction is applied, the fine particles of the substance tend to penetrate the layer of asbestos for some distance and the filter rapidly becomes clogged.—W. P. S.

Ensilage process; Effects of the —— *on the solubility of "floats."* E. B. Forbes and C. M. Fritz. J. Ind. Eng. Chem., 1914, 6, 222—223.

EXPERIMENTS were made to ascertain whether it would be practicable to add "floats" to corn before introducing the latter into the silo, instead of applying the "floats" to the soil directly admixed with manure. Ensilage was effected for six months in closed earthenware jars and the product from corn to which "floats" had been added in the proportion 1 : 250, appeared identical in taste, odour, and appearance with that from untreated corn: the content of phosphorus soluble in 0·2 per cent. hydrochloric acid increased considerably during ensilage. The average composition of the samples before and after ensilage are shown in the following table:—

Product.	Total P.	Water-sol. P.	Citrate-sol. P.	Inorgan. P sol. in 0·2 per cent. HCl.
	per cent.	per cent.	per cent.	per cent.
Untreated green silage corn	0·207	0·149	0·021	0·083
Silage from untreated corn	0·224	0·160	0·008	0·111
Green silage corn, plus "floats" (250 : 1) ..	0·371	0·136	0·061	0·172
Silage from treated corn	0·384	0·157	0·060	0·237

See also this J., 1912, 895.)—A. S.

Butter fat [*in butter*]; *Rapid method for the gravimetric determination of* ——. F. König. Apoth.-Zeit., 1914, 29, 223—224.

ONE grm. of the butter is treated in a 200 c.c. cylinder with 9 c.c. of hot water, and when melted, 2 c.c. of ammonia, 10 c.c. of alcohol, 20 c.c. of ether, and 20 c.c. of petroleum spirit (b. pt. about 40° C.) are added, shaking after each addition. The whole is shaken thoroughly for 1 min., set aside for 15 mins., the cylinder inverted and, by carefully loosening the cork, the aqueous layer allowed to flow away. About 0·4 grm. of powdered tragacanth is then added, and, after shaking, the ethereal solution is decanted into a weighed flask; the gelatinous mass in the cylinder is then washed with petroleum spirit, the washings being added to the flask, the solvent is evaporated from the latter, and the residue of butter fat dried and weighed. —W. P. S.

Cottonseed meal; The organic phosphoric acid of ——. R. J. Anderson. J. Biol. Chem., 1914, **17,** 141—150. (See also this J., 1912, 701, and 1913, 42.)

The acid was extracted from cottonseed meal by digestion with 0·2 per cent. hydrochloric acid and was freed from inorganic phosphate and bases other than baryta by repeated slow precipitation of the crystalline barium salt from its solutions in dilute hydrochloric acid; a process which was effected alternately by the addition of barium hydroxide and of alcohol to the solutions. Although the reactions of the free acid were identical with those of phytic acid, which is usually assigned the formula $C_6H_{24}O_{27}P_6$, analyses of the barium salts agreed more closely with the formula, $C_6H_{18}O_{24}P_6$, of inositol hexaphosphate; by suitably adjusting the conditions of crystallisation two salts were obtained, corresponding to tri-barium inositol hexaphosphate, $C_6H_{12}O_{24}P_6Ba_3$ and hydrated hepta-barium inositol hexaphosphate, $(C_6H_{11}O_{24}P_6)_2Ba_7$. The free acid was obtained as a colourless syrup which gave no reaction with ammonium molybdate. (See also succeeding abstracts.)—J. R.

Oats; Phytin in ——. R. J. Anderson. J. Biol. Chem. 1914, **17,** 151—163.

The substance was isolated in the form of barium salt from 0·2 per cent. hydrochloric acid extracts of oats by precipitation with barium chloride; purification was effected by repeatedly precipitating the salt from dilute hydrochloric acid alternately with alcohol and barium hydroxide. The snow-white amorphous powder thus obtained was resolved into two substances by treatment with small quantities of cold water. The undissolved portion crystallised readily, and two salts were isolated from it identical with those obtained from cottonseed meal (see preceding abstract). These salts readily yielded inositol when heated in a sealed tube with dilute sulphuric acid. The soluble barium salt, which remained amorphous and differed markedly from the crystalline product, resembles a substance isolated in a similar manner from wheat bran.—J. R.

Corn [maize]; Phytin in ——. R. J. Anderson. J. Biol. Chem., 1914, **17,** 165—170.

By treatment similar to that recorded in the foregoing abstracts the meal yielded a white amorphous barium salt which gave analytical results corresponding with the usually accepted formula, $C_6H_{18}O_{27}P_6Ba_3$, of tri-barium phytate. Further treatment resulted in the isolation of two crystalline barium salts identical in every respect with those described above.—J. R.

Phytin; A contribution to the chemistry of ——. R. J. Anderson. J. Biol. Chem., 1914, **17,** 171—190.

Neuberg's formula (Biochem. Zeits., 1908, **9,** 551—557) for phytic acid, $C_6H_{24}O_{27}P_6$, differs by 3 mols. of water from the formula, $C_6H_{18}O_{24}P_6$, of inositol hexaphosphate, which was suggested for phytic acid by Suzuki and Yoshimura (this J., 1907, 1061). Salts prepared from commercial phytin without especial purification are usually amorphous and give analytical results corresponding closely with Neuberg's formula. The author has succeeded, however, in isolating from the crude amorphous barium salt two crystalline barium salts identical with those obtained from cottonseed meal, etc. (see preceding abstracts). From the analytical data these substances are salts of the acid $C_2H_6O_8P_2$ or $C_6H_{18}O_{24}P_6$. The composition of the free phytic acid obtained from crystalline barium phytate also agrees well with these formulæ, indicating that phytic acid is either inositol hexaphosphate or an isomeric substance. The free acid, and to a lesser degree the salts, decompose slowly under ordinary conditions with liberation of inorganic phosphate, but without formation of inositol. The latter substance is produced when the acid is dried at 105° C. under reduced pressure. The other products in both cases are stated to be barium salts of penta- to mono-phosphoric acid esters of inositol. The acid is always hydrolysed appreciably on drying.—J. R.

Detection of adulteration of saffron by means of phosphomolybdic acid. Verda. *See* IV.

Patents.

Fish, crayfish, crabs, lobsters, molluscs, and the like; Process for preserving ——. A. Danilevsky, St. Petersburg. Eng. Pat. 8775, April 14, 1913.

Fish, crabs, etc., are placed alive in a solution consisting of water, 100 parts, sodium chloride, 1 to 2, and hydrogen peroxide, 0·01 to 0·5 part. After a period of from 1 to 5 hours, the dead fish, etc., are removed from the solution, wrapped in linen impregnated with a preserving solution, and stored in a refrigerating chamber. Fish preserved in this manner may, it is stated, be dried directly in the air, or smoked, without risk of decomposition. (See also this J., 1914, 215.)—W. P. S.

Hydrogenated [fat] product. C. Ellis, Montclair, N.J. U.S. Pat. 1,087,161, Feb. 17, 1914.

An edible product of butter-like consistence consists of a mixture of hydrogenated cottonseed oil and hydrogenated palm oil. (See also U.S. Pat. 1,037,881; this J., 1912, 1004.)—W. P. S.

Cream; Process of producing ——. W. E. McCaddon, Assignor to H. M. De Witt, Denver, Colo. U.S. Pat. 1,087,599, Feb. 17, 1914.

A column of liquid, consisting of a milk product and a fat, is impelled upwards to a point of discharge against a resistance produced by its own weight, the force employed exceeding the said pressure to a predetermined degree.—W. P. S.

Grain-purifying process. E. H. Reynolds, Chicago. U.S. Pat. 1,087,684, Feb. 17, 1914.

Grain is treated with a quantity of sodium chloride solution sufficient to raise the moisture-content to about 15 per cent., and is then subjected to the action of sulphurous acid fumes.—W. P. S.

Cocoa and chocolate; Process of preparing ——. F. E. F. Neumann. Fr. Pat. 463,325, Oct. 6, 1913.

To obtain products having a uniform taste, the cocoa-mass is formed into a layer about 1 mm. thick and heated to 100°—150° C., for a few seconds. The thin layer is then exposed to the atmosphere for a time, and again heated, these operations being repeated until the desired effect is attained.—W. P. S.

Manufacture of vinegar from milk. Fr. Pat. 463,266. *See* XVIII.

XIXb.—WATER PURIFICATION; SANITATION.

Chlorides in drinking water; Importance of the amount of —— *for control and evaluation.* M. F. Malméjac. Comptes rend., 1914, **158,** 650—652.

The sources of the chlorine in drinking water are the soil through which the rainfall passes and the excreta of living beings. From the first source the amount of chlorine is markedly constant for any one water and is generally small, viz., 13 to 20 mgrms. per litre, though in deep wells the quantity may rise to 1 grm. per litre. From the second source, the amount of chlorine is variable and accidental, though often considerable. Analyses of

various waters are given showing the concurrence between the results for the variable chlorine and those for organic matter of animal origin as estimated by the oxygen absorption in an alkaline medium, and the relation between the chlorine and the number and kind of bacteria present; any sudden increase in chlorine was accompanied by an increase in the bacteria and the appearance of *B. coli.*
—J. H. J.

Sewage disposal. G. J. Fowler. Times Eng. Suppl., Mar. 11, 1914.

Sewage sludge is now very generally being sold as a manure. At Manchester the "slurry" from the washing of the contact beds is being dried, powdered and sold to Canada at a price which covers cost. At Bradford the crude sewage is "cracked" with sulphuric acid, the resulting sludge hot pressed, the grease recovered and sold at a profit, and the residual sludge cake sent to Northern France for intensive gardening. At Oldham the sludge is distilled and the residue sold. At Dublin the sludge is fermented by yeast, which causes a separation of water; the solid sludge is dried and the resulting powder sold for 50s. a ton (see also this J., 1914, 157). An organism has been isolated from the water of an old colliery which has the property of precipitating iron in presence of organic matter. When this organism was added to an effluent together with a salt of iron and then air blown in, complete clarification was obtained; the deposit produced had a high nitrogen content.—J. H. J.

Disinfectants; New method for determining the value of ——. C. A. Duyser and W. K. Lewis. J. Ind. Eng. Chem., 1914, **6**, 198—200.

Portions of the disinfectant are diluted with known quantities of water and a measured volume of a standard bacteria culture is introduced into each of the solutions and into solutions of pure phenol of equal concentration. After allowing to stand for an exact number of minutes, an aliquot part of each mixture is plated out in Petri dishes on nutrient agar and incubated until the colonies representing the surviving bacteria can be counted; plates of equal dilutions of the culture but without disinfectant are also incubated. The ratio of surviving organisms to the number present on the undisinfected plates is then plotted against the dilution, whereby two curves, one for the phenol and one for the disinfectant, are obtained, from which the relative strength of the disinfectant compared with that of phenol can be read off at any desired point. The curves for the so-called emulsion disinfectants are practically straight lines which can be plotted from the results of a small number of tests. It is stated that the results can be duplicated with sufficient accuracy even by two analysts working separately. The degree of accuracy attainable is shown by the following results of duplicate determinations: 4·82, 4·58; 5·17, 5·05; 6·95, 6·64; 9·64, 9·30; 4·28, 4·08; 2·04, 2·24.
—A. S.

Formaldehyde and its polymerides; The vapours of ——. F. Auerbach and W. Plüddemann. Arbb. Kais. Gesundh.-Amt, 1914, **47**, 116—132. Chem. Zentr., 1914, **1**, 956.

α-Polyoxymethylene when vaporised in a current of dry air at 40°—100° C., and β-polyoxymethylene under similar conditions at 40°—60° C., yield almost exclusively polyoxymethylene vapour, the β-compound changing, in part, into the stable α-compound. Anhydrous formaldehyde vapour diluted with nitrogen can be prepared by vaporising α-polyoxymethylene in a current of warm nitrogen, dissociating the vapour by heating to 220°—230° C., and then separating the residual polymerides by cooling to —25° to —30° C. In the vaporisation of solid polyoxymethylenes for disinfecting purposes, the active formaldehyde is produced only by the dissociating action of water or steam, and then only slowly and incompletely: hence a relatively larger quantity is necessary than when aqueous solutions of formaldehyde are used. In the iodometric analysis of formaldehyde solutions, the iodine and alkali solutions should not be mixed before addition of the formaldehyde. Alkaline solutions of formaldehyde should be neutralised and again made alkaline after addition of the iodine (an excess of at least 50 per cent. over the quantity consumed).—A. S.

New method for the determination of the salts of water. Windisch and others. *See* XVIII.

Dehydration of glycerol by a ferment occurring in water. Voisenet. *See* XVIII.

Patents.

Liquids; Sterilisation of ——. R. F. Edwards, London. Eng. Pat. 8500, April 10, 1913.

The liquid, such as water, milk, or the like, is sprayed or atomised into a chamber containing lamps capable of emitting ultra-violet rays; the treatment may take place *in vacuo*, in air, or in the presence of an inert gas.
—W. P. S.

Water; Process for adding coagulants to ——. A. P. Strohmenger, London. Eng. Pat. 22,050, Sept. 30, 1913.

The water is conducted under pressure through a tube containing an aluminium rod of slightly smaller diameter than the tube; this rod is connected with the positive pole of a source of electricity and the tube with the negative pole. For example, the tube may have an internal diameter of 1$\frac{3}{8}$ inch and contain an aluminium rod 3 ft. in length and $\frac{7}{8}$-inch in diameter, and water, under a pressure of 8 lb. per sq. inch, may be passed through it at the rate of 100 galls. per hour. With water containing 20 parts of total solids per 100,000, a difference of potential of 3 volts will produce 0·072 grm. of aluminium hydroxide per 100 galls. of water.—W. P. S.

Water; Purification of ——. F. M. Leavitt, Smithtown, N.Y., Assignor to Leavitt-Jackson Engineering Co., Brooklyn, N.Y. U.S. Pat. 1,088,232, Feb. 24, 1914.

A gas under pressure is introduced into the water, the supply of gas, irrespective of its pressure, being controlled by its loss of weight; the rate of the loss of weight is regulated by the rate of flow of the water.—W. P. S.

Alumino-silicate compounds for the purification of water; Process of manufacturing ——. P. de Brünn. First Addition, dated Sept. 27, 1913, to Fr. Pat. 455,391, Mar. 10, 1913 (this J., 1913, 958).

A dilute solution of an alkali aluminate is mixed with a solution of an alkali silicate, suitable soluble salts are added, and the precipitate formed on heating is collected, washed, and dried. For instance, 845 c.c. of a solution of sodium aluminate, containing 45·6 grms. Al_2O_3, and 315 grms. of a solution of sodium silicate, containing 75 grms. SiO_2, are added to a solution of 2·75 kilos. of sodium sulphate in 54·5 litres of water. Or, 25 kilos. of crystallised aluminium sulphate are dissolved in 135 litres of water, 31 kilos. of a 40·7 per cent. solution of sodium hydroxide are added, the mixture is added to 4500 litres of a 5 per cent. solution of sodium sulphate, and 26·25 kilos. of solution of sodium silicate, containing 25 per cent. SiO_2, are introduced.—W. P. S.

Water; Process for sterilising —— *by means of vessels lined with radio-active cement.* H. Farjas. Fr. Pat. 463,352, Dec. 13, 1912.

The water is stored in closed receptacles lined with cement containing radio-active minerals or concentrates.
—W. P. S.

Sewage, waste water, etc.; Purifying apparatus for ——. A. Girard. First Addition, dated Sept. 17, 1913, to Fr. Pat. 416,814, June 6, 1910. Under Int. Conv., Sept. 25, 1912.

A series of shallow basins or trays is arranged in steps, with weirs in between, each basin containing a layer of material such as coke. The liquid to be treated is allowed to flow over a weir into the first basin and thence through the series.—W. P. S.

Water; Process for purifying ——. W. Drechsler, Dresden, Germany. U.S. Pat. 1,088,063, Feb. 24, 1914.

See Eng. Pat. 1416 of 1913; this J., 1913, 922.—T. F. B.

Water; Process for purifying ——. Leavitt-Jackson Engineering Co. Fr. Pat. 463,317, Oct. 6, 1913. Under Int. Conv., Oct. 8, 1912.

See U.S. Pat. 1,088,232 of 1914; preceding.—T. F. B.

Steriliser. P. G. Triquet, Paris. U.S. Pat. 1,089,990, March 10, 1914.

See Addition of May 26, 1912, to Fr. Pat. 434,069 of 1910; this J., 1912, 948.—T. F. B.

Liquids; System for treating —— with ozone. M. Fuss, Frankfort, Germany, Assignor to General Electric Co., New York. U.S. Pat. 1,090,044, March 10, 1914.

See Fr. Pat. 401,599 of 1909; this J., 1909, 1162.—T. F. B.

Human and animal bodies and their organs; Process of the hardening or mummification of ——. G. and P. Fratarcangeli, Frosinone, Italy. U.S. Pat. 1,088,977, March 3, 1914.

See Eng. Pat. 6095 of 1912; this J., 1913, 449.—T. F. B.

Process for obtaining gas from sewage sludge. Ger. Pat. 270,338. *See* IIa.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Quinine; Occurrence of —— in the seeds of Cinchona Ledgeriana, Moens. P. van Leersum. Pharm. Weekblad, 1913, **50**, 1464—1467. Chem. Zentr., 1914, **1**, 994.

According to Moens ("*Chinakultur in Asien*") the seeds of *C. Ledgeriana* contain 6·13 per cent., those of *C. officinalis* 13·3, and those of *C. succirubra* 9·5 per cent. of fat, but no alkaloid. The author has detected quinine in *C. Ledgeriana* seeds. The powdered seeds were extracted with petroleum ether, dried, ground, and treated with slaked lime. The resulting powder was treated with caustic soda solution, extracted with benzene, and the alkaloids (yield 0·38 per cent. on the dried seeds) recovered from the benzene solution by means of hydrochloric acid. Quinine was identified by means of its tartrate. The seeds yielded also 18·6 per cent. of a greenish yellow oil of sp. gr. 0·930 at 18° C., $\alpha_D^{20} = -26°$ in a 200 mm. tube. —A. S.

Quinine salts; Some coefficients of precipitability of —— in saline solutions of various concentrations. N. Tarugi. Gaz. chim. ital., 1914, **44**, I., 131—151.

Solutions of different salts (chlorides of sodium, potassium and calcium and sodium nitrate) of various concentrations were added gradually to a definite volume of a solution of quinine hydrochloride ($C_{20}H_{24}N_2O_2.HCl.2H_2O$) of known concentration until a turbidity was produced, and determinations were also made by performing the operation in the reverse direction. From the results, the proportions of the salt and of the quinine hydrochloride (both expressed in grms. per 100 c.c.) in the solution when a turbidity was just produced were calculated and also the relative solubility product (concentration of salt × concentration of quinine hydrochloride). The detailed results are given in tables. In the case of calcium chloride, the relative solubility product mentioned was approximately constant, the mean value being 6·43, but in the other cases it varied with the concentration of the salt, as shown in the following table:—

Sodium chloride.		Sodium nitrate.		Potassium chloride.	
Conc. of NaCl.	Relative sol. prod.	Conc. of $NaNO_3$.	Relative sol. prod.	Conc. of KCl.	Relative sol. prod.
grms. per 100 c.c.		grms. per 100 c.c.		grms. per 100 c.c.	
2·02	5·2	0·677	1·9	2·63	6·69
2·18	4·9	0·778	1·9	2·85	6·2
2·49	4·85	0·869	1·8	3	5·64
2·66	4·85	0·970	1·8	4·16	4·86
3·40	4·1	1·14	1·59	5·57	4·17
4·08	3·55	1·23	1·34	8·26	4·38
8·34	2·82	2·008	1·34	10·12	4·24
9·12	2·88	3·455	1·53	12·71	3·71
11·40	2·33	3·65	1·54	17·87	3·66
13·39	2·22	9·21	2·67	19	3·15
15·56	2·17	11·05	2·97	23·16	2·61
17·64	1·94	13·13	2·73	25·74	2·56
19·83	1·48	19·12	2·23	—	—
—	—	25·18	2·45	—	—
—	—	31·78	2·09	—	—

The data given may be utilised for the rapid determination of the concentration of a solution of quinine hydrochloride, a known volume of the latter being titrated with one of the saline solutions (of known concentration) until a turbidity is produced, and the concentration (C) of the salt in the total solution then calculated. Then if calcium chloride has been used, $\frac{6\cdot43}{C}$ gives the concentration of the quinine hydrochloride in the total solution, whilst in the case of the other salts, this concentration is obtained by dividing C into the corresponding relative solubility product as ascertained from the table. The varying solubility of the hydrochlorides of the cinchona alkaloids in saline solutions may also be used for the detection of down to 3 per cent. of the hydrochlorides of cinchonine or cinchonidine in quinine hydrochloride. 25 c.c. of the solution of the hydrochloride are saturated in the cold with sodium nitrate, filtered after 3 hours, and 5 c.c. treated with 1·5 c.c. of ammonia solution of sp. gr. 0·88: a turbidity is produced if cinchonine or cinchonidine be present.—A. S.

Belladonna plant; Alkaloids in ——. A. F. Sievers. Amer. J. Pharm., 1914, **86**, 97—112. (See also this J., 1914, 40.)

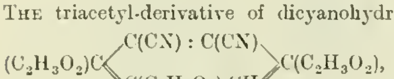
Belladonna plants were dried at 60° C. and the alkaloid determined in the various portions, with the following average results:—Four third-year plants: flowers 0·385; flowering tops, 0·865; leaves, 0·475; stems, 0·292; roots, 0·448; entire plant, 0·444 per cent.; six first-year plants: leaves, 0·686; young sprouts, 0·9315; fruit, 0·3192; stems, 0·1145; roots, 0·1605; entire plant, 0·343 per cent. In the early summer, the herb, including the leaves, tops and small stems could be advantageously picked if the herb instead of the leaves were officinal. Small leaves of both belladonna and *Datura* contained more alkaloid than large leaves, and young and small stems and roots were richer than large and old stems and roots. The woody part of the roots was richer than the bark.—F. Shdn.

Yohimbine and quebrachine; Identity of ——. E. Fourneau and H. J. Page. Bull. Sci. Pharmacol., 1914, **21**, 7—16. Chem. Zentr., 1914, **1**, 986—987.

A comprehensive investigation of yohimbine (from *Corynanthe Yohimba, N.O. Rubiaceæ*) and quebrachine (from *Quebracho blanco, N.O. Apocynaceæ*) and of their salts has shown that the two alkaloids are identical. The free base when freshly precipitated dissolves easily in absolute alcohol, but almost immediately separates from the solution in the anhydrous form, which is soluble in 25 parts of cold and 10 parts of boiling absolute alcohol. It crystallises in prismatic needles of the composition, $C_{21}H_{26}N_2O_3$, m.pt. 247°—248° C. (Maquenne block), $[\alpha]_D^{20} = +56°$ to 56·1° in alcoholic solution. A solution of the alkaloid in concentrated sulphuric acid gives a violet colouration with potassium bichromate. The alcoholic solution is coloured yellow by ferric chloride and by nitric acid, and gives a white precipitate with bromine water. The hydrochloride, $C_{21}H_{26}N_2O_3,HCl$, melts at 302°—303° C., the sulphate, $(C_{21}H_{26}N_2O_3)_2H_2SO_4,8H_2O$, after dehydration, at 281°—282° C., and the tartrate, $(C_{21}H_{26}N_2O_3)_2C_4H_7O_6$, $6H_2O$, at 213° C. (278° C. when anhydrous.)—A. S.

Trimethoxyphthalic acids ; Constitution of some ——. *II.* G. Bargellini. Gaz. chim. ital., 1914, **44**, I., 182—192.

The triacetyl-derivative of dicyanohydroxyquinol,



$$(C_2H_3O_2)C\left\langle\begin{array}{l} C(CN):C(CN) \\ C(C_2H_3O_2)\cdot CH \end{array}\right\rangle C(C_2H_3O_2)$$

, prepared as described by Thiele and Günther (Annalen, 1906, **349**, 45), was converted by the action of dimethyl sulphate and potassium hydroxide into the trimethyl ether of dicyanohydroxyquinol, and from the latter 3.4.6-trimethoxyphthalic acid was obtained by boiling with a concentrated solution of potassium hydroxide. After purification the acid melted at 212°—213° C. when heated slowly, but this was really the melting point of the anhydride ; when heated rapidly the acid melted at about 185° C., losing water and then solidifying again. This acid appears to be identical with the trimethoxyphthalic acid of m.pt. 202° C. prepared by Feist (this J., 1907, 1159) by oxidation of the methyl ether of columbamine ; the low melting point observed by Feist was probably due to the presence of impurities. These results and those obtained previously (this J., 1912, 1146) show that in the alkaloids of Columba root (columbamine and jateorhizine) the three methoxy (or hydroxy) groups are disposed asymmetrically, whilst in colchicine they are in adjacent positions.—A. S.

Limonene ; Conversion of —— *into carvomenthene and menthane.* G. Vavon. Bull. Soc. Chim., 1914, **15**, 282—287.

The catalytic hydrogenation of limonene in presence of platinum black was carried out at ordinary temperatures by agitation in an atmosphere of hydrogen. The absorption proceeded in two distinct stages, two atoms being first added on to the side chain with the production of active carvomenthene, and this being later converted into inactive menthane. The rotatory power of carvomenthene is given as $[\alpha]_{578}=+118°$, $[\alpha]_{436}=+234$; and of its nitrosochloride (m.pt. 95° C.) $[\alpha]_{578}=+344°$, $[\alpha]_{436}=+724°$. The hydrochloride, $C_{10}H_{19}Cl_{578}$, is inactive and hence symmetrical.—G. F. M.

Oxalacetic ester. H. Gault. Comptes rend., 1914, **158**, 711—714.

Oxalacetic ester on keeping changes slowly to oxalocitric lactone, by the elimination of one mol. of alcohol from two of the ester. The rapidity of the change depends upon the initial degree of purity of the specimen. At 150° C. from 70 to 80 per cent. of the ester was lactonised in 4 hours. Dilute potassium carbonate solution hastens the reaction, but strong solutions yield a separation of the potassium derivative, which, unlike the corresponding derivative of the lactone, is practically insoluble in the carbonate solution. The potassium derivative is very stable under ordinary conditions, so that it is advisable to purify and preserve the ester in this form. Upon acidifying in the cold it yields the perfectly pure ester. This distils unchanged under reduced pressure, whereas the lactone cannot be distilled. The lactone is readily converted into propanetetracarboxylic ester and tricarballylic acid.—J. R.

Patents

Monosalicylide ; Process for the production of ——. E. Kopetschni, Berlin, L. Karczag, Szolnok, Hungary, and O. Fodor, Berlin. Eng. Pat. 7875, April 3, 1913. Under Int. Conv., April 3, 1912.

See U.S. Pat. 1,075,581 of 1913 ; this J., 1913, 1085. The same product is obtained by heating salicylic chloride *in vacuo*.—T. F. B.

Unsaturated hydrocarbons ; Manufacture of ——. W. H. Perkin, Manchester, F. E. Matthews, E. H. Strange, and H. J. W. Bliss, London. Eng. Pat. 29,988, Feb. 15, 1913.

Amino-alcohols may be converted into doubly unsaturated hydrocarbons by heating with catalysts, such as phosphoric acid ; diluting vapours or gases may be used and the pressure in the reaction vessel may be reduced (compare Eng. Pats. 3873 and 12,771 of 1912 ; this J., 1913, 449, 711).—T. F. B.

Isoprene ; Process of making ——. C. Ruder, Wandsbek, Germany. U.S. Pat 1,087,261, Feb. 17, 1914.

The vapour of terpineol or "a terpineol substance" is subjected to a temperature sufficiently high to decompose the cyclic compound and to produce isoprene, at a pressure not exceeding that of the atmosphere. The vapour may be passed over a heated metal spiral.—T. F. B.

Isoprene and its homologues ; Process for preparing ——. A. Gerlach and R. Koetschau. Ger. Pat. 268,722, Sept. 10, 1912.

The mono- or di-hydrochloride of a singly or doubly unsaturated terpene is treated with a heated substance which has the power to remove hydrogen chloride, at a temperature above 500° C., a relatively small amount of the hydrochloride being brought in contact with a large surface of the soda-lime or other agent used for the purpose. The process may be carried out under reduced pressure, or in presence of a diluent gas, such as carbon dioxide. The crystalline hydrochloride may be melted and dissolved in a small quantity of terpene or an indifferent solvent, and the solution allowed to fall in drops on the soda-lime in an iron vessel or an iron or porcelain tube. The hydrochlorides of pinene, dipentene, sylvestrene, and limonene are converted into isoprene, whilst those of the terpenes, C_6H_{10} and C_8H_{12} are transformed into erythrene and dimethylerythrene.—T. F. B.

Pinene ozonide. Cinnamic aldehyde ozonide. W. J. Knox, New York, Assignor to Knox Terpezone Co. of America. U.S. Pats. 1,086,372 and 1,086,373, Feb. 10, 1914.

The ozonides of pinene and cinnamic aldehyde, the preparation of which is described in Eng. Pat. 27,371 of 1912 (see this J., 1913, 924) are claimed as being white, opaque substances. Pinene ozonide is also claimed to be an inhalable germicidal compound.—T. F. B.

Alcohols from chlorhydrocarbons ; Preparation of ——. W. E. Masland, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,086,381, Feb. 10, 1914.

A monohalogen derivative of a saturated aliphatic hydrocarbon is converted into the corresponding alcohol by heating with zinc oxide. The process may be applied to other halogen compounds in which the halogen is attached to an alkyl group.—T. F. B.

Casein calcium and process for producing the same. P. Sprenger and A. Tschudi, Basle, Switzerland, Assignors to Hoffmann-La Roche Chemical Works, New York. U.S. Pat. 1,087,515, Feb. 17, 1914.

A solution of casein calcium of about 10 per cent. strength is converted into a dry, white, stable powder, easily soluble in water and in milk, by drying it in the form of drops and preventing the drops from touching the surface of the drying vessel until the water has evaporated. For example, the drops may be exposed to a column of warm air produced by a number of fine jets of high velocity, so as to suspend the drops until they are dry.—T. F. B.

Bismethylaminotetra-aminoarsenobenzene ; Preparation of derivatives of —— *easily soluble in water to neutral solutions.* C. F. Boehringer und Söhne. Ger. Pat. 269,660, Jan. 24, 1913.

bis-Methylaminotetra-aminoarsenobenzene (see U.S. Pat. 1,081,079 ; this J., 1914, 41) is dissolved in water in presence of an alkali bicarbonate or ammonium bicarbonate, and the product is separated from the solution by addition of an organic solvent. The resulting salts, which are probably carbamates, are suitable for therapeutic purposes, *e.g.*, for intramuscular injection.—T. F. B.

Arsenic-phosphorus, arsenic-arsenic, arsenic-antimony, arsenic-selenium, and arsenic-tellurium compounds ; Process for preparing mixed organic ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pats. 269,699 and 269,700, Oct. 8 and 19, 1912.

(1) The hydrogen compounds of phosphorus, arsenic, antimony, selenium, and tellurium react with aromatic arseno-dichlorides, forming the compounds mentioned in the title. (2) The corresponding arsenoxides may be used in place of the dichlorides. In this case, however, the arsenic-tellurium compounds cannot be obtained in a pure state, owing to the hydrogen telluride being oxidised by the arsenoxide.—T. F. B.

Arsenic-bismuth compounds ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 269,745, Sept. 27, 1912. Addition to Ger. Pat. 269,743 (see Eng. Pat. 17,533 of 1913 ; this J., 1913, 1030).

An aromatic arsine is made to react with a bismuth compound containing the grouping, -Bi(halogen)$_2$. —T. F. B.

3.3′-Dinitro-4.4′-dihydroxyarsenobenzene ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pats. 269,886 and 269,887, Oct. 11, 1912, and Jan. 9, 1913. Additions to Ger. Pat. 206,456.

(1) 3-Nitro-4-hydroxybenzene-1-arsinic acid, or the corresponding arsenoxide, is reduced by means of stannous chloride, preferably in presence of hydriodic acid, whereupon 3.3′-dinitro-4.4′-dihydroxyarsenobenzene is produced, the nitro groups not being reduced by this process. (2) Hypophosphorous acid is used as a reducing agent in place of stannous chloride.—T. F. B.

Cantharidyl-ethylenediamine ; Process for preparing salt-like double compounds of ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 269,661, Aug. 2, 1912.

The condensation product of cantharidine and ethylenediamine of the empirical formula, $C_{12}H_{18}O_3N_2$, is treated with a gold salt. The products are extremely active bactericides, and may be used in the treatment of tuberculosis by injection into human beings or animals.—T. F. B.

Hexamethylenetetramine-methyl thiocyanate ; Process for preparing ——. K. H. Schmitz. Ger. Pat. 269,746, April 8, 1913. Addition to Ger. Pat. 266,788.

Instead of using isolated hexamethylenetetramine itself, as described in the principal patent (this J., 1913, 1032), a mixture of concentrated solutions of ammonia and of formaldehyde, or of concentrated ammonia solution and a polymeride of formaldehyde, is used.—T. F. B.

Carbamic esters ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 269,938, April 13, 1913.

Glycol ethers of the formula, $HO.CH_2.CH_2.OR$ (where R represents a simple or substituted aryl group) are converted by the usual methods into the corresponding urethanes $X_2N.CO.O.CH_2.CH_2.OR$, which possess powerful antipyretic and analgesic properties.—T. F. B.

Alcohols from chlorhydrocarbons ; Preparation of ——. E. C. R. Marks, London. From E. I. du Pont de Nemours Powder Co., Wilmington, Del., U.S.A. Eng. Pat. 29,964, Dec. 30, 1912.

See U.S. Pat. 1,086,381 of 1914 ; preceding.—T. F. B.

Aldehydes and ketones from monohalogen derivatives ; Manufacture of ——. Fabriques de Prod. de Chimie Organique de Laire, Issy, France. Eng. Pat. 5533, March 5, 1913. Under Int. Conv., March 7, 1912.

See Fr. Pat. 452,537 of 1912 ; this J., 1913, 673.—T. F. B.

Esters of [hydr]oxy fatty acids ; Process for the manufacture of ——. Chem. Werke vorm. Dr. H. Byk, Lehnitz-Nordbahn, Germany. Eng. Pat. 11,741, May 20, 1913. Under Int. Conv., June 3, 1912.

See Fr. Pat. 458,645 of 1913 ; this J., 1913, 1086.—T. F. B.

Cantharidine compounds suitable as a remedy for tuberculosis ; Manufacture of ——. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 17,693, Aug. 1, 1913. Under Int. Conv., Aug. 1, 1912.

See Ger. Pat. 269,661 of 1912 ; preceding.—T. F. B.

Benzyl acetate ; Manufacture of ——. F. W. Klever, Cologne, Germany. Eng. Pat. 20,501, Sept. 10, 1913. Under Int. Conv., Sept. 11, 1912.

See Fr. Pat. 462,439 of 1913 ; this J., 1914, 277.—T. F. B.

Organic compounds ; Separation of —— *at low temperatures.* W. E. Masland, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,087,961, Feb. 24, 1914.

See Fr. Pat. 453,165 of 1913 ; this J., 1913, 767.—T. F. B.

Ozonides ; Apparatus for the production of gaseous ——. W. J. Knox, New York, Assignor to Knox Terpezone Co. of America. U.S. Pat. 1,088,346, Feb. 24, 1914.

See Eng. Pat. 27,371 of 1912 ; this J., 1913, 924.—T. F. B.

Alkylalkoxymethyl esters of cresotinic acids. J. Callsen, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,088,966, March 3, 1914.

See Eng. Pat. 16,387 of 1913 ; this J., 1913, 1030.—T. F. B.

p-Nitrosophenylglycine ; Process for making ——. J. D. Riedel A.-G. Fr. Pat. 463,333, Oct. 7, 1913. Under Int. Conv., Oct. 8, 1912.

See Eng. Pat. 22,694 of 1913 ; this J., 1914, 70.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patents.

Dyestuffs employed in photography ; Process for sensitising ——. J. H. Smith, Bois-Colombes, France. U.S. Pat. 1,089,594, March 10, 1914.

See Fr. Pat. 413,222 of 1910 ; this J., 1910, 1135.—T. F. B.

Colour photography ; Process for producing polychromatic screens, plates, films, and paper for ——. J. Szczepanik, Luisenhof, Germany. U.S. Pat. 1,089,602, March 10, 1914.

See Eng. Pat. 17,065 of 1908 ; this J., 1908, 1178.—T. F. B.

Kinematograph films ; Plastic material used in the manufacture of ——. H. Danzer, Assignor to Comp. Générale de Phonographes, Cinématographes, et Appareils de Précision, Paris. U.S. Pat. 1,089,910, March 10, 1914.

See Fr. Pat. 443,031 of 1911 ; this J., 1912, 1008.—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose; Solubility of —— in ether-alcohol. A. Matteoschat. Z. ges. Schiess- und Sprengstoffw., 1914, **9,** 105—106.

Five grms. of nitrocellulose, containing N 12·95 per cent., which had been dried at 60° C., was shaken with alcohol, and ether (sp. gr. 0·720) then added. 505 c.c. of the mixed solvents were added, there being a contraction of 5 c.c. on mixing. The mixture was shaken for 1 hour, allowed to stand overnight, then agitated frequently during the course of the day and allowed to stand for 40 hours. 100 c.c. of the clear liquid were then drawn off, evaporated, the residue dried for 24 hours at 70° C., and weighed. Four different samples of alcohol were employed containing respectively 99·5, 95·0, 90·0 and 80·0 per cent. of alcohol. With equal quantities of ether and alcohol, solubilities of 52·3, 42·3, 28·7, and 14·2 per cent. were obtained, with the varying concentrations of alcohol respectively mentioned above. When the ratio of ether to alcohol was 2 to 1 and 3 : 1, solubilities of 40·5, 52·4, 53·9 and 45·0 per cent., and 25·0, 42·4, 53·0 and 57·5 per cent. respectively were obtained.—G. W. McD.

Nitro-compounds of benzene and toluene. W. Will. Ber., 1914, **47,** 704—717.

As a factor in the prevention of accidents in manufacture, the chemical properties of the trinitrotoluenes were studied. Attempts to prepare isomerides other than the three known, by increase of pressure, temperature, or time of nitration, gave rise to trinitrobenzoic acid, the salts of which would be a source of danger in manufacture, or to tetranitromethane. The constitution of γ-trinitrotoluene was confirmed; the β-modification was proved to be the 2.3.4-trinitrotoluene. As explosives, the three isomerides differed but little; γ-trinitrotoluene was somewhat more sensitive to impact than α-trinitrotoluene, and less so than β-trinitrotoluene. The α-isomeride was less readily attacked by alkalis than the other two, which formed sensitive salts of dinitrocresol. With alkali and an oxidising agent, α-trinitrotoluene formed hexanitrodibenzyl. With acetone and ammonia, α-, β-, and γ-trinitrotoluene gave respectively a red, a yellowish-green, and a blue colouration. The existence of tetranitrobenzene, and of the dinitrodinitrosobenzene melting at 133° C. (Nietzki, Ber., 1901, **34,** 55) was not confirmed. —O. E. M.

Explosion at the works of the Aktien-Gesellschaft für Anilinfabrikation, Rummelsberg, Germany. Chem. Ind., 1914, **37,** 149—150.

Without starting the stirrer or the cooling water, a workman in the nitrobenzene factory ran the nitrating acids into the benzene, the charge forming two layers. When the stirring-gear was thrown in, heat was suddenly evolved, the cover of the apparatus was blown off, and the escaping nitrobenzene and benzene vapour formed with the air a mixture which exploded spontaneously, or was fired by sparks from fragments of the iron vessel or by hemp packing or straw set on fire by projected acid. The use of interlocking cocks was adopted after a somewhat similar accident at another works.—O. E. M.

Nitro-compounds; Explosion of ——. P. W. Uhlmann. Chem.-Zeit., 1914, **38,** 389—390.

Dinitrophenol forms explosive salts with alkalis, ammonia, etc., and should not be heated with them in closed vessels; highly nitrated substances should not be heated in autoclaves at all. At moderate temperatures nitro-compounds do not explode in contact with sulphuric acid: even dinitrodiazobenzene can be heated to 50° C. in very concentrated acid. Dinitronaphthalene and dinitroanthraquinone have fired, without exploding, during manufacture. The possible causes of the Rummelsberg explosion are discussed; interlocking, to prevent the opening of the acid cock before the cooling water and stirring gear are started, is recommended. (See preceding abstract.)—O. E. M.

Heat Test Committee. *See under* Official Notice, page 337.

Patents.

Explosive; Manufacture of an ——. C. Claessen. Fr. Pat. 463,714, Oct. 17, 1913.

Hexanitroethane is used as an explosive, alone or in combination with other substances, *e.g.*, propellant powder: nitrocellulose (68 parts), hexanitroethane (16), trinitrotoluene (9), and diethyldiphenylurea (7 parts); blasting explosive: trinitrotoluene (36 parts) and hexanitroethane (64 parts).—G. W. McD.

Explosive cartridges containing liquid oxygen. Soc. L'Air Liquide (Soc. anon. pour l'Etude et l'Exploit. des Proc. G. Claude). Fr. Pat., 463,876, Dec. 28, 1912.

Lampblack of apparent density 0·2—0·25, obtained, for example, by the incomplete combustion of naphthalene, is used as an absorbent for about four times its weight of liquid air. Naphthalene may also be added. A special long detonator which brings the priming charge near the middle of the cartridge has to be used in order to prevent missfires. (See also this J., 1913, 627, 768, 769, 843, 1131).—G. W. McD.

Guncotton and smokeless powder. L. Guiguet. Fr. Pat. 464,028, Jan. 3, 1913.

To produce cellulose free from foreign matter cotton waste is dissolved, the solution filtered, and formed into threads of a thickness of from 1 to 3 deniers, which are then nitrated.—G. W. McD.

XXIII.—ANALYTICAL PROCESSES.

Fluorine in reagents. P. Carles. Ann. Chim. Analyt. 1914, **19,** 101—104.

Sulphuric and hydrochloric acids are generally quite free from fluorine but the authors were unable to find any nitric acid which did not contain it. Nitric acid free from the impurity can be obtained by distilling, and rejecting the first two-fifths which come over. Potassium nitrate and probably also sodium nitrate contain fluorine from which they cannot be freed by repeated recrystallisation. To obtain these salts pure it is necessary to precipitate the fluorine as barium fluoride by boiling a solution of the alkali nitrate with a little barium nitrate and then adding sufficient barium hydroxide solution to make the liquid just alkaline, the excess of barium being subsequently removed by precipitation with carbon dioxide. The nitrate obtained by double recrystallisation is then free from fluorine. Commercial caustic baryta contains large quantities of fluorides but these are entirely insoluble in water and a perfectly clear solution of barium hydroxide is free from fluorine. Barium acetate is not free from fluorine unless its solutions are neutral and perfectly clear. Barium chloride is usually free from the impurity but sodium and potassium bicarbonates and ammonium carbonate always contain fluorine. Glacial acetic acid, separated by pouring off the mother liquor from the crystals, does not contain fluorine.—J. A.

Arsenic, copper, and iron; Iodometry of ——. G. D. Lander and J. J. Geake. Analyst, 1914, **39,** 116—121.

The method described by Avery and Beans (this J., 1901, 936) for the iodometric determination of arsenious acid in the presence of copper yields correct results, and may also be applied to mixtures of arsenite with ferric, but not with ferrous, chromium, nickel, cobalt, bismuth, and zinc salts, and to the determination of arsenic acid, for instance, in copper arsenate, after the arsenic acid has been reduced with sulphur dioxide in the presence of sulphuric acid. Antimony may be titrated in a similar manner in the presence of cupric, ferric, and bismuth salts. The following process may be used for the determination of cuprous and cupric salts in mixtures of the same, for example, in commercial cuprous chloride. A quantity of 0·1 grm. of the salt is dissolved in dilute hydrochloric acid, boiled water is added, the solution cooled, an excess of potassium iodide introduced, and the liberated iodine titrated with thiosulphate: this gives the amount of cupric salt present. Sodium potassium tartrate, a slight excess of solid sodium bicarbonate, and an excess of standard iodine solution are then added to the solution, and the excess of iodine titrated with thiosulphate. The quantity of iodine used is equivalent to the total cuprous salt now present, and the amounts of cuprous and cupric salt contained originally in the sample may be calculated. Attempts to determine ferrous salts by oxidation with iodine in the presence of alkali tartrate and sodium bicarbonate did not yield quite satisfactory results and attention is drawn to the fact that iodine reacts to a certain extent with sodium bicarbonate in solution.—W. P. S.

Titanium; Determination of —— as phosphate. G. S. Jamieson and R. Wrenshall. J. Ind. Eng. Chem., 1914, **6**, 203—205.

For the determination of titanium in ferrotitanium or in ores, the authors recommend the method of Ericson (Iron Age, Aug. 27, 1903) in which iron is reduced to the ferrous state by means of ammonium bisulphite or sulphur dioxide and then the titanium precipitated as phosphate in acid solution by adding ammonium phosphate and boiling. In the case of ores containing only small quantities of titanium, after dissolving by treatment with hydrochloric and sulphuric acids and evaporating with sulphuric acid, the solution should be neutralised with ammonia, and then again made acid with hydrochloric acid before proceeding with the determination. For quantities of titanium up to 3 mgrms., precipitation is effected in 50 c.c. of solution containing 3 c.c. of hydrochloric acid (1 : 1); for larger quantities, in 100 c.c. of solution containing 15 c.c. of acid. The iron may also be reduced by hydrogen sulphide in presence of tartaric acid, the ferrous sulphide being dissolved in hydrochloric acid and the determination continued as usual. When tartaric acid is added, titanium can be determined in presence of aluminium by this method.
—A. S.

Kjeldahl method [for estimating nitrogen]; Some limitations of the ——. H. D. Dakin and H. W. Dudley. J. Biol. Chem., 1914, **17**, 275—280.

It is usually stated that Kjeldahl's method is not directly applicable to substances containing nitrogen linked directly to oxygen or to nitrogen: the authors find that the method is also unsuitable for pyridine and derived substances, and that with piperidine, quinoline, isoquinoline, acridine and their derivatives, accurate results can only be secured after very prolonged heating (about 4 hours). The use of potassium bichromate in the method appears to obviate the difficulty in the case of pyridine. Other cyclic nitrogen compounds presented no difficulty, but it is recommended that in all cases of this kind control analyses should be made with pure substances.—J. R.

PATENTS.

Thermocouples for pyrometry. R. W. Paul. London. Eng. Pat. 12,708, May 31, 1913.

One member of the thermo-couple consists of a tube and cap, so as totally to enclose the other member.—B. N.

Detectors of combustible gases. A. Philip and L. J. Steele, Portsmouth. Eng. Pat. 5467, March 4, 1913.

A catalytically-active wire and an inactive wire are joined alternately in a Wheatstone bridge with resistance elements, and the relative changes in resistance are observed by the readings of a galvanometer in a battery circuit. The galvanometer is joined to the resistance elements, through sliding contacts, adjustable, *e.g.*, by means of a screw, as a means of securing an initial zero reading. The active and inactive wires are surrounded by tubes, the one round the inactive wire being provided with adjustable openings for equalising the heat losses by radiation from the wires, so as to secure a practically constant reading. A window is provided in the case surrounding the active wire for observing the glowing of the wire in a combustible atmosphere.—B. N.

Gaseous mixture ; Apparatus for determining a definite constituent of a —— by the absorption method. Drägerwerk H. und B. Dräger. Ger. Pat. 270,088, Feb. 21, 1913.

A vessel containing the sample of gas is combined with a manometer for measuring the reduction of pressure due to absorption of one of the constituents. The absorbent is contained in a receptacle inside the gas vessel, normally fastened gas-tight to the cover of the latter, but forced away therefrom by a rod, or by a screw which also serves to close the opening provided for equalising the pressure before making a determination.—A. S.

Inflammable-gas indicator. A. Guasco, Paris. U.S. Pat. 1,089,050, March 3, 1914.

See Fr. Pat. 437,585 of 1911 ; this J., 1912, 560.—T. F. B.

Chemical analysis ; Means for use in ——. J. G. Hume, Duns, Scotland. U.S. Pat. 1,087,239, Feb. 17, 1914.

See Eng. Pat. 21,076 of 1910 ; this J., 1911, 1233.—T. F. B.

Apparatus for testing [grading] coal or ores. Eng. Pat. 4992. *See* IIA.

Apparatus for applying tensile and compressive tests to cement, concrete, and the like. Eng. Pat. 6645. *See* IX.

Books Received.

Die Medikamentösen Seifen. Ihre Herstellung und Bedeutung unter Berücksichtigung der zwischen Medikament und Seifengrundlage möglichen chemischen Wechselbeziehungen. Ein Handbuch für Chemiker, Seifenfabrikanten, Apotheker und Aertzte. Von Dr. Walter Schrauth. Julius Springer's Verlag. Berlin, W 9, Linkstr. 23—24. 1914. Price M. 6. Bound M. 6.60.

This volume (9½ by 6½ ins.) contains 159 pages of subject matter, with alphabetical indexes of names, subjects, and one of technical proprietary terms, with names and addresses of proprietors, etc. This is preceded by a list of German patents and patentees with claims, and trade names of medicated soaps defined. The subject-matter itself is classified as follows :—I. Soap as a washing, disinfecting, and curative agent. II. General technology of medicated soaps. III. Special composition of medicated soaps. IV. Methods for the examination and testing of medicated soaps. V. Legal regulations relating to the dealing in and dispensing of medicated soaps.

A Text-Book of Organic Chemistry. By A. F. Holleman, Ph.D., etc., Professor Ord. in Amsterdam University. Edited by A. Jamieson Walker, Ph.D., assisted by O. E. Mott, Ph.D. Fourth Edition. John Wiley and Sons, Inc. New York. 1914. Price 10s. 6d. Chapman and Hall, Ltd., London.

This volume (9¼ by 6 ins.) containing 590 pages of subject-matter with 79 illustrations, and an alphabetical index of subjects. The text is classified as follows :—I. Introduction. Qualitative and quantitative analysis. Molecular weight determinations. Laboratory methods, etc. II. Aliphatic compounds. III. Cyclic compounds. (*a*) Alicyclic compounds, and (*b*), Aromatic compounds. IV. Alkaloids.

A Laboratory Manual of Organic Chemistry for Beginners. By A. F. Holleman, Ph.D. Professor Ord. University of Amsterdam. An Appendix to the Author's Text Book of Organic Chemistry. Edited by A. Jamieson Walker, Ph.D., B.A. John Wiley and Sons, Inc., New York. Chapman and Hall, Ltd., London. 1913. Price 4s. 6d.

Volume (7¾ by 5 ins.), contains 74 pages of subject matter, and an alphabetical index.

Summary Report of the Mines Branch of the Department of Mines for the Calendar Year ending December 31st, 1912. Canada Dept. of Mines, Ottawa. No. 224 (No. 26a, 1913). Price 15 cents.

Magnetite Occurrences along the Central Ontario Railway. By E. Lindeman. Canada Dept. of Mines, Ottawa. Mines Branch Rept. No. 184.

Austin Brook Iron-bearing District, New Brunswick. By E. Lindeman. Canada Dept. of Mines, Ottawa. Mines Branch Rept. No. 105.

Explosives ; Tests of Permissible ——. By Clarence Hall and Spencer P. Howell. Bulletin 66. U.S. Bureau of Mines, Washington.

The results are given of all explosives permissible in coal mining in the United States, tested between May 15, 1909 and March 1, 1913. A copy of the test requirements and the names of explosives on the permissible list are appended.

Symboles Internationaux. Commission Electrotechnique International. Secrétaire Général, 28, Victoria Street, Westminster, S.W. Price 2s.

Contains preface, remarks on the standardisation of symbols, rules for quantities, tables of symbols adopted, units and signs for names of units, mathematical symbols and rules, abbreviations for weights and measures, and name for electrical unit.

Poisons and Habit-Forming Drugs. By Martin I. Wilbert and Murray G. Motter. Reprint No. 146 from the Public Health Reports. U.S. Public Health Service, Washington.

A digest of laws and regulations relating to the manufacture, sale, use, and possession of poisons and habit-forming drugs enacted during 1912 and 1913, now in force in the United States.

Dust and Gas Explosions in Coal Mines ; Notes on the Prevention of ——. By George S. Rice. Technical Paper 56. U.S. Bureau of Mines, Washington.

Suggestions and recommendations with a view to decrease the number and extent of mine explosions.

Explosives in Coal Mining. Use and Misuse of——. Miners' Circular 7. By J. J. Rutledge, with a preface by Jos. A. Holmes, U.S. Bureau of Mines, Washington.

METALLURGICAL COKE. By A. W. BELDEN. U.S. Bureau of Mines, Washington. Technical Paper 50.

A SUMMARY of the history of coke making in the United States, indicating the development of modern methods and types of oven, and giving the composition and physical properties of metallurgical cokes produced in the United States.

BULLETIN OF THE DEPT. OF AGRICULTURE, TRINIDAD AND TOBAGO. Vol. XIII. No. 77, Trinidad. Price 3d.

CONTAINS "manurial experiments on cocoanuts." By JOS. DE VERTEUIL.

OIL-SEEDS, OILS, FATS AND WAXES. Selected Reports from the Scientific and Technical Department, Imperial Institute. [Colonial Reports No. 88, Miscellaneous.] V. (In continuation of No. 82 [Cd. 6022], January, 1912.) Wyman and Sons, Ltd., 49, Breams Buildings, Fetter Lane, London, E.C., and 28, Abingdon Street, S.W., and 54, St. Mary Street, Cardiff; or, H.M. Stationery Office (Scottish Branch), 23, Forth Street, Edinburgh; or, E. Ponsonby, Ltd., 116, Grafton Street, Dublin. [Cd. 7260]. Price, 8½d.

VOLUME (9¾ by 6⅛ ins.) containing 595 pages of subject matter, and an alphabetical index.

INTERMETALLIC COMPOUNDS. By CECIL H. DESCH, D.Sc., Ph.D. Graham Young Lecturer in Metallurgical Chemistry in the University of Glasgow. Longmans, Green and Co., 39, Paternoster Row, London, New York, Bombay and Calcutta. 1914. Price 3s. net.

VOLUME, containing 108 pages of subject matter with 17 illustrations, 4½ pages of references, and an alphabetical index. The text is subdivided and classified as follows:—I. Thermal analysis. II. Microscopic structure. III. Isolation of intermetallic compounds. IV. Native intermetallic compounds. V. Physical properties. VI. Existence of intermetallic compounds in the liquid state. VII. Relations of intermetallic compounds to carbides, silicides, etc. VIII. Ternary compounds.

INDIA-RUBBER LABORATORY PRACTICE. By W. A. CASPARI, B.Sc., Ph.D., etc. Macmillan and Co., Ltd. St. Martin's Street, London. 1914. Price 5s. net.

VOLUME (7¾ by 5 ins.), containing 177 pages of subject matter, with 25 illustrations, appendix with statistics, tables, etc., filling 11 pages, and an alphabetical index of subjects. The text is classified as follows:—I. Crude and washed rubber. II. Machinery and apparatus. III. Rubber diluents. IV. Solid compounding materials. V. Miscellaneous accessories. VI. Specific gravities. VII. Analysis of manufactured rubber (organic). VIII. Analysis of manufactured rubber (inorganic). IX. Gutta-percha and Balata.

LABORATORY MANUAL OF GLASS BLOWING. By FRANCIS C. FRARY, Ph.D. McGraw-Hill Book Company, Inc., 239, West 39th Street, New York, and 6, Bouverie Street, London, E.C. 1914. Price 3s. 2d. net.

VOLUME (7¾ by 5¼ ins.), containing 57 pages of subject matter with 18 illustrations, and an alphabetical index of subjects. The text is subdivided as follows:—I. Materials and apparatus. II. General operations. III. Elementary exercises. IV. Advanced exercises. V. Modified methods and special operations.

KARBIDE UND SILIZIDE. Von Prof. Dr. OTTO HÖNIGSCHMID. [Monographien über angewandte Elektrochemie.] Wilhelm Knapp's Verlag. Halle (Saale). 1914. Price M. 13.60.

VOLUME (9¾ by 6¾ ins.) containing 258 pages of subject matter with alphabetical indexes of names of authors and subjects. There are 22 illustrations. The carbides and silicides of the metals are fully treated, methods of preparation and properties being given. There is an appendix, in which thermal analysis is first explained, and then applied to the cases of the silicides and carbides. Polymorphic changes in these groups are described, with methods, and in reference to various silicides (iron, nickel, cobalt, manganese and copper), and also carbides.

KURZES HANDBUCH DER KOHLENHYDRATE. Von Dr. B. TOLLENS, O.H. Professor auder Universität Göttingen, &c., Dritte Auflage. Johann Ambrosius Barth's Verlag. Leipzig. 1914. Price M. 22. Bound M. 23.50.

VOLUME (8¾ by 5⅞ ins.) containing 795 pages of subject matter, with 29 illustrations, and an alphabetical index of subjects. The subject matter is classified as follows:—I. Properties, occurrence, formation, and distribution, etc. of the carbohydrates. II. Detailed description and treatment of the carbohydrates. III. Polysaccharides and saccharo-colloids, amorphous or crystallisable with difficulty. IV. Polyhydric alcohols of the glucoses. V. Acids of the carbohydrate group, including the aldehyde-acids, the saccharins and saccharinic acids.

A THIRD YEAR COURSE OF ORGANIC CHEMISTRY. The Heterocyclic Compounds, Carbohydrates, and Terpenes. By T. P. HILDITCH, D.Sc. Methuen and Co., Ltd., 36, Essex Street, London, W.C. 1914. Price 6s.

VOLUME (7½ by 5 ins.) containing 391 pages of subject matter with numerous diagrams, and an alphabetical index of subjects, and index of authors. The subject matter is classified briefly as follows:—I. Heterocyclic compounds. II. Three- and four-membered rings, etc. III. Lactones, thetines, and betaines. IV. Five-membered rings. V. Five-membered polyhetero-atomic rings: The azoles. VI. Six-membered rings: Pyrones, Chromones, etc. VII. Six-membered mono-heterocyclic rings. VIII. The alkaloids, etc. IX. The purines. X. The polypeptides. XI. Carbohydrates, etc. XII. The terpenes, etc.

Journal of the Society of Chemical Industry.

No. 8, Vol. XXXIII. APRIL 30, 1914. No. 8, Vol. XXXIII.

The Society of Chemical Industry.

Past Presidents.

Rt. Hon. Sir Henry Roscoe, LL.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., F.R.S.	1882—1883.
†Walter Weldon, F.R.S.	1883—1884.
†Sir Wm. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt, LL.D.	1885—1886.
David Hnward	1886—1887.
Sir James Dewar, M.A., LL.D. F.R.S.	1887—1888.
†Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D.,D.Sc., F.R.S.	1891—1892.
†Sir John Evans, K.C.B., F.R.S.	1892—1893.
†E. C. C. Stanford	1893—1894.
Sir Edward Tborpe, C.B., LL.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Beilby, LL.D., F.R.S.	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.
Sir Wm. Bamsay, K.C.B., D.Sc., F.R.S.	1903—1904.
Wm. H. Nichols, M.S., LL.D., D.Sc.	1904—1905.
†Edward Divers, M.D., D.Sc., F.R.S.	1905—1906.
Eustace Carey	1906—1907.
Sir Boverton Redwood, Bart., D.Sc.	1907—1908.
Raphael Meldola, F.R.S.	1908—1909.
Prof. Ira Remsen	1909—1910.
Walter F. Reid	1910—1911.
Rudolph Messel, Ph.D., F.R.S.	1911—1912.
Prof. Marston T. Bogert, LL.D.	1912—1918.
Sir William Crookes, O.M., Pres.R.S.	1913.

† Deceased.

LIST OF COUNCIL, 1913–1914.

President : Dr. Rudolph Messel., F.R.S.

Vice-Presidents :

Julian L. Baker.
Sir Hugh Bell, Bart.
Prof. Marston T. Bogert.
Dr. Charles C. Carpenter.
Prof W. Hodgson Ellis.
Sir Richard Garton.
H. Hemingway.
Prof. G. G. Henderson.
E. Grant Hooper.
Prof. W. J. Pope, F.R.S.
Walter F. Reid.
Maximilian Toch.

Ordinary Members of Council :

W. J. A. Butterfield.
Enstace Carey.
R. B. Clayton.
Prof. F. G. Donnan, F.R.S.
Dr. M. O. Forster, F.R.S.
D. Lloyd Howard.
Dr. Charles A. Keane.
W. J. Leonard.
G. W. MacDonald.
N. H. Martin.
Dr. W. Lash Miller.
J. Miln Thomson.

Sectional Chairmen and Secretaries :

BIRMINGHAM.	*H. T. Pinnock.*	F. R. O'Shaughnessy.
CANADIAN.	*Prof. R. N. Ruttan.*	Alfred Burton.

L. J. de Whalley, B.Sc.	XVII.

Birmingham Section.

Chairman : H. T. Pinnock.

Vice-Chairmen :

W. J. Rees. E. C. Rossiter.

Committee :

H. W. Brownsdon.
J. E. Coates.
O. F. Hudson.
F.C.A.H.Lantsberry
E. A. Lewis.
J. C. Mann.
B. S. Morrell.
S. S. Napper.
W. B. Parker.
E. W. Smith.
A. E. Tucker.
Jno. Wilson.

Hon. Local Secretary and Treasurer :

F. R. O'Shaughnessy, 42, Temple St., Birmingham.

The following take office after the Annual General Meeting : *Committee :* N. P. Booth. W. W. Butler, Harold Holcroft, T. Slater Price, Harry Silvester.

Canadian Section.

Chairman : R. F. Ruttan.

Vice-Chairmen :

J. W. Bain. W. L. Goodwin, T. H. Wardleworth.

Committee :

C. F. Bardorf.
W. P. Cohoe.
J. A. De Cew.
Nevil N. Evans.
L. F. Guttmann.
C. F. Heebner.
Milton L. Hersey.
W. R. Lang.
A. McGill.
W. Lash Miller.
H. P. Mills.
R. T. Mohan.
A. Nieghorn.
Otto G. Palm.
J. F. Snell.
O. H. Wurster.

Hon. Treasurer : E. G. R. Ardagh.

Hon. Local Secretary :

Alfred Burton, 2–16, Liberty Street, Toronto.

Asst. Hon. Secretary for Montreal:

Joel B. Saxe, 171, St. James Street, Montreal.

The following take office after the Annual General Meeting : *Chairman :* J. W. Bain ; *Vice-Chairman :* S. B. Chadsey ; *Committee:* L. T. Acton, F. O. Farey, R. F. Ruttan, and A. G. Spencer.

Liverpool Section.

Chairman : E. C C. Baly.
Vice-Chairman : Arthur Carey.

Committee :

H. Baker.
Eustace Carey.
J. Gray.
W. R. Hardwick.
Max Muspratt.
W. H. Roberts.
Wm. Ramsay.
H. J. L. Rawlins.
H. B. Stocks.
J. W. Towers.
Stuart J. Willcox.

Hon. Treasurer :
W. P. Thompson, 6, Lord Street, Liverpool.

Hon. Local Secretary :
Alex. Rule, The University, Liverpool.

The following take office after the Annual General Meeting: *Committee :* J. Harger, A. Holt, and H. E. Potts.

London Section.

Chairman :—W. R. E. Hodgkinson.
Vice-Chairman : A. R. Ling.

Committee :

W. J. A. Butterfield.
F. H. Carr.
A. Chaston Chapman.
E. Hatschek.
H. Hemingway.
E. Grant Hooper.
Bernard Howard.
C. A. Keane.
R. Lessing.
T. D. Morson.
W. F. Reid.
Thomas Tyrer.
J. C. Umney.

Hon. Local Secretary and Treasurer :
J. H. Coste, Utopia, Gloucester Road, Teddington.

The following take office after the Annual General Meeting: *Committee :* J. K. Crow, J. L. Foucar, C. A. Hill, G. W. MacDonald, and R. Seligman.

Manchester Section.

Chairman : Julius Hübner.
Vice-Chairman : J. H. Hoseason.

Committee :

J. Allan.
E. Ardern.
H. J. Bailey.
R. H. Clayton.
G. J. Fowler.
W. B. Hart.
T. Jackson.
S. E. Melling.
C. Rawson.
F. H. Terleski.
T. R. Wollaston.
M. Wyler.

Hon. Local Secretary :
L. E. Vlies, Belmont, Gowan Road, Alexandra Park, Manchester

The following take office after the Annual General Meeting: *Committee :* P. Gaunt, B. Hart, T. Jackson, H. Levinstein, W. Thomson, and S. Wolff.

Newcastle Section.

Chairman : T. W. Lovibond.
Vice-Chairman : E. F. Hooper..

Committee :

P. P. Bedson.
S. H. Collins.
J. T. Dunn.
E. M. Fletcher.
W. Gemmell.
T. Hardie.
G. P. Lishman.
H. Louis.
N. H. Martin.
C. J. Potter.
A. Short.
J. Watts.

Hon. Local Secretary and Treasurer :
F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

The following take office after the Annual General Meeting: *Chairman :* F. C. Garrett; *Vice-Chairman :* T. W. Lovibond; *Committee :* W. Diamond, C. H. Ridsdale, H. D. Smith. *Secretary :* E. F. Hooper.

New England Section.

Chairman : S. W. Wilder.
Vice-Chairman : (vacant.)

Committee :

F. E. Atteaux.
C. G. Bird.
D. J. Danker.
W. C. Durfee.
C. H. Fish.
C. L. Gagnebin.
R. Hütz.
H. P. Knapp.
W. D. Livermore.
L. A. Olney.
W. K. Robbins.
B. E. Schlesinger.
H. J. Skinner.
W. S. Williams.

Hon. Treasurer :
Frank W. Atwood, 216, Milk Street, Boston, Mass., U.S.A.

Hon. Local Secretary :
A. A. Claflin, 88, Broad Street, Boston, Mass., U.S.A.

New York Section.

Chairman : G. W. Thompson.
Vice-Chairman : J. E. Teeple.

Committee :

J. Alexander.
C. A. Doremus.
T. R. Duggan.
W. M. Grosvenor.
Martin H. Ittner.
J. M. Matthews.
Eugene Merz.
H. S. Miner.
H. R. Moody.
T. J. Parker.
Albert Plaut.
G. W. Sargent.
M. C. Whitaker.

Hon. Treasurer : Frank C. R. Hemingway, 17, Battery Place, New York City, U.S.A.

Hon. Local Secretary :
P. C. McIlhiney, 7, East 42nd Street, New York City, U.S.A.

The following take office after the Annual General Meeting: *Committee :* Carleton Ellis, E. F. Hicks, A. Lichtenstein, Gilbert Rigg, Allen Rogers.

Nottingham Section.

Chairman : Sir John Turney.
Vice-Chairman : S. R. Trotman.

Committee :

L. Archbutt.
J. Dunford.
F. Stanley Kipping.
D. J. Law.
H. B. Mayfield.
C. E. B. Merriman.
W. G. Timmans.
H. J. Wheaton.
J. White.
J. M. Wilkie.
J. T. Wood.

Hon. Treasurer :
S. J. Pentecost, Lenton Works, Nottingham.

Hon. Local Secretary :
H. J. S. Sand, University College, Nottingham.

The following take office after the Annual General Meeting: *Chairman:* John White; *Vice-Chairmen :* Sir John Turney and S. R. Trotman; *Committee :* T. H. Adams, T. F. Harvey.

Scottish Section.

Chairman : Thos. Ewan.
Vice-Chairman :

Committee :

Thomas Callan.
Wm. B. Clark.

Official Notice.

ANNUAL GENERAL MEETING, 1914.

In accordance with the provisions of By-law 64, notice is hereby given that the Annual General Meeting will be held at University College, Nottingham, at 10.30 a.m., on Wednesday, July 15th, 1914. A programme of the proceedings will be issued later.

In accordance with the provisions of By-law 24, those members whose names are printed in *italics* in the List of Council will retire from their respective offices at the forthcoming Annual Meeting.

Prof. G. G. Henderson, D.Sc., has been nominated to the office of President under By-law 20; Mr. N. H. Martin, Dr. W. H. Nichols, and Mr. Harry Silvester have been nominated Vice-Presidents under By-law 21, and Sir Wm. Crookes, O.M., President R.S., has been nominated a Vice-President under By-law 20; Mr. Thos. Tyrer and Dr. R. Messel, F.R.S., have been reappointed Hon. Treasurer and Hon. Foreign Secretary respectively.

In accordance with the provisions of By-law 72, notice is hereby given that the Council has awarded the Society's Medal to the Rt. Hon. Sir Henry Roscoe, LL.D., F.R.S., for his conspicuous services to science, to education, and to this Society.

Members are requested to nominate, on or before May 22nd next, fit and proper persons to fill four vacancies among the Ordinary Members of Council. Forms for this purpose can be obtained from the Secretary of the Society.

By-law 23:—An ordinary member of Council shall be nominated by ten or more members upon Form B in the Schedule, a copy of which form shall be furnished by the Secretary upon the written or verbal request of any member, but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form. A nomination shall be declared invalid by the Council if:

a. The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the By-laws.

b. The nomination is not made on the authorised printed form or substantially not in the manner directed thereon.

c. The nomination form is signed by less than ten members not disqualified or not ineligible to nominate as provided by the By-laws.

d. The nomination form is not received before or upon the day appointed therefor.

e. The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid, shall receive notice thereof from the Secretary, and shall not be submitted for election.

Canadian Section.

Meeting held at Toronto on Thursday, 18th December, 1913.

PROF. J. W. BAIN IN THE CHAIR.

THE EVOLUTION OF THE REFUSE DESTRUCTOR.

BY DR. E. KOHLMANN.

The removal and disposal of municipal refuse in a sanitary and economical manner, has always been one of the most acute problems of civic administration. Formerly the city waste was either dumped upon plots of land, usually located on the outskirts of the city, or used as a fertilizer. However, with the rapidly increasing growth of the cities, these dumps, which were mostly breeding places for all kinds of germs and were also sources of annoyance in many ways, had to be done away with, and the area formerly occupied by them was converted into building land. Relatively to the growth of the cities the value of the refuse decreased; the refuse lost its fertilizing properties so that the demand from the agriculturists lessened.

The necessity for disposal of the waste in an economical and sanitary manner thus became more and more urgent, and many efforts were made to discover the best method.

The only perfectly sanitary way in use up to the present time had been considered that of incineration. Incineration was first started in England. In 1874, a dust contractor, Fryer, built an experimental furnace, which was improved upon by the erection at Manchester, in 1876, of the first efficient type of furnace, called a "destructor," consuming all forms of town's refuse in an unseparated condition. His invention originated from the knowledge of the large amount of carbonaceous matter in English refuse; even now if the composition of refuse, brown-coal, and peat is compared, it is apparent that the calorific value of refuse in some cities, especially where anthracite or pit-coal is burnt, is as high as that of raw brown-coal and peat But more recently the value of the inferior constituent parts has been realised, and this knowledge has been the basis for the further evolution of destructors.

The incinerator of Fryer deserves attention, in so far that a number of destructors of this type were installed all over England, and according to whether rear or top charging was adopted, a number of different systems were introduced. The furnaces themselves had all as a rule a single oblique grating on which the refuse was burnt. The escaping gases passed either through openings at the rear of the furnaces or through holes in the covering vaults.

On the same principle the first plant on the European continent was built in 1896, at Hamburg, but with certain alterations. In place of Fryer's grating the Hamburg Board of Management introduced a grate with numerous conical-shaped holes; the reason for this alteration was that a perforated sheet-iron plate distributes the draught more uniformly over the whole mass of refuse which is being consumed. Fig. 1 shows a diagram of the first Hamburg destructor of the Horsfall type. The gas outlet is seen in the covering vaults. The second alteration of importance was the adoption of fans instead of steam jet-blowers. To promote combustion English furnaces used steam jet-blowers, but, as condensed steam absorbs the heat, it would have been practically impossible to consume the Hamburg refuse, which is of inferior combustible composition.

Independent of Hamburg the firm of Herbertz at Cologne (Germany) came to the same conclusion that a perforated grate with the fan in lieu of the steam jet-blower, was an advantage over the English styles, and in 1900 they first brought out a destructor improved on these lines. The cell of Herbertz retained a rectangular plan similar to that of the English furnaces, but the flue was arranged too close to the grate so that only a very limited quantity of refuse could be treated. But as the perforated plate works with much higher draught and a much greater efficiency per square foot of grate results, a limit was soon attained as to the size of the grate and the cell above which the operator could not manage the cake of clinker.

Then Herbertz introduced the small cell of 1·2 sq. yds. of grate area against 3·3 sq. yds. of the English furnaces To obtain a balance of the fluctuating temperature in the single cell, several cells were combined to one furnace block, and a system of mutual support established; English engineers in the meantime had also adopted similar ideas. But Herbertz took a further step. To avoid possible fluctuation of temperature in the separate cell, he made 2 or 3 small charges on the grate before he removed the clinker cake. Thus the criteria of Herbertz's furnace are small cell and small individual charges. (Fig. 2.)

Previous to the introduction of this system in Fiume and Brünn (Austria) and Kiel (Germany) in 1905 and 1906 respectively, the plants of Brussels and Zürich had been constructed in 1903 and 1904 respectively.

Up to this time the English furnaces show no marked improvement. In 1903, however, Messrs. Hughes and Stirling, two English engineers, had erected the destructor plant of Frederiksberg (Denmark), in which the system of mutual support of a group of cells is adopted similarly to the Herbertz system. By the arrangement of 4 cells in one group, the partition wall is partly done away with, so that the gases of one cell escape through the other. This double cell was the beginning of the

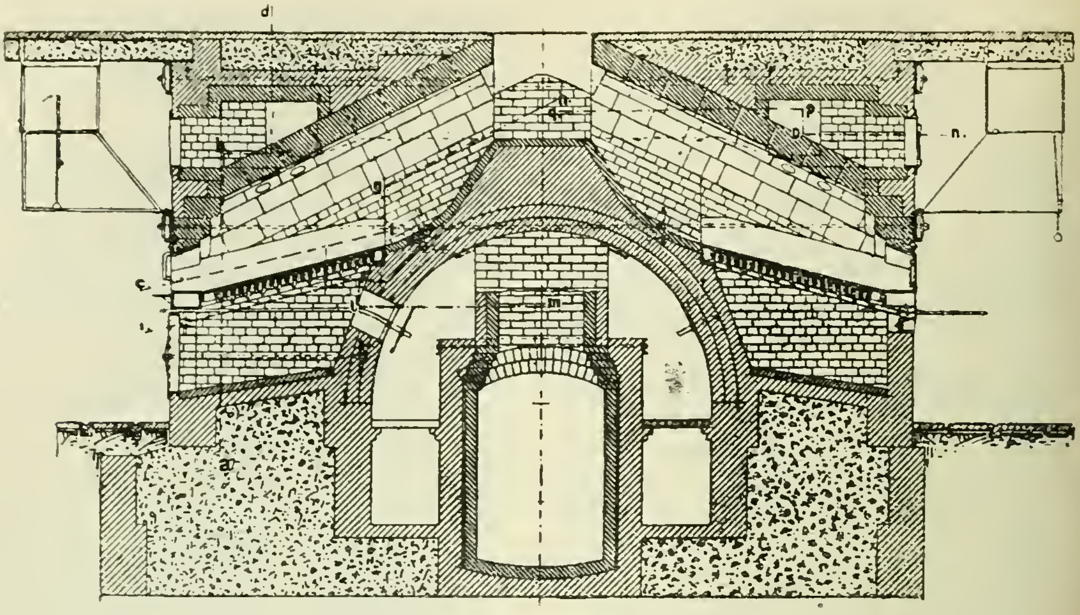

FIG. 1.—First Hamburg Destructor, Horsfall Type.

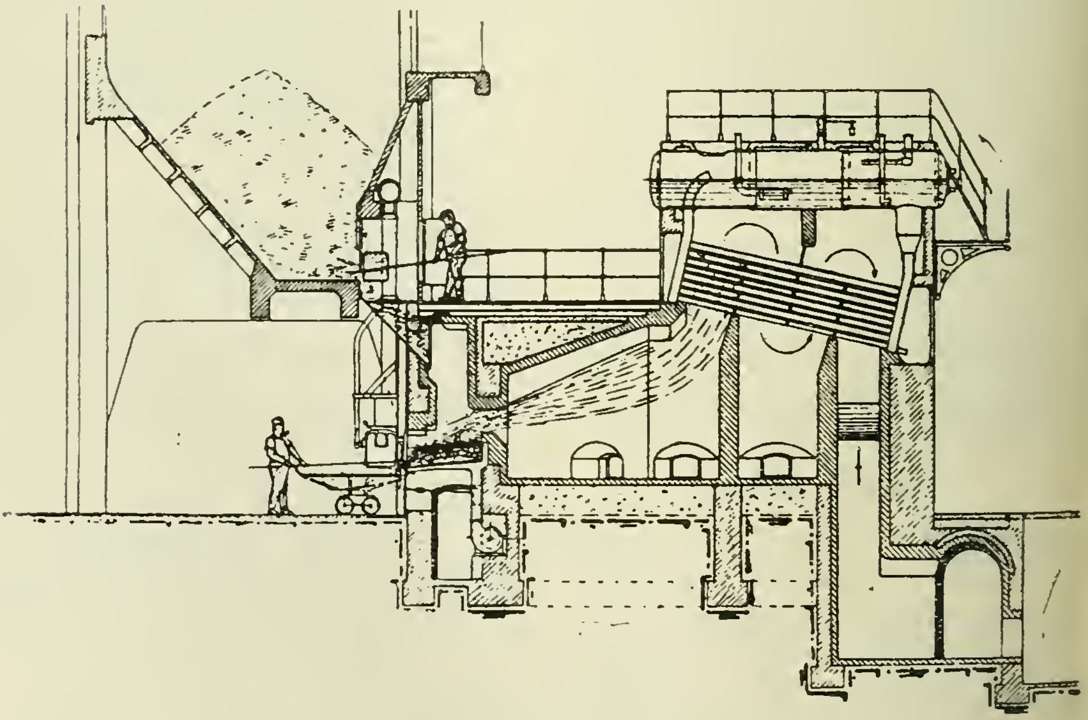

FIG. 2.—The Herbertz Furnace.

continuous grates, widely used in England, in which the division wall disappears wholly and a broad grate results, the parts of which are charged and discharged alternately. An example of this plant may be seen at Seattle (Wash., U.S.A.). The destructor has a capacity of 60 tons, and is constructed on the Meldrum system.

The objection to this type is that the removal of clinker could not practically be effected without derangement of separate parts, so that it has given place to that of Frederiksberg, where the division of cells is at least indicated by a small wall above the grate. This partition has been constructed in order to separate each cake into smaller portions and to facilitate the handling of clinker. However, these division walls suffered greatly from the adherence of clinker and from heat so that it was necessary to cool them by the incoming draught. The grate thus resulting consisted now of a bottom part and two sid walls, and an exceedingly favourable shape of grate wa obtained, namely, the mould grate (Fig. 3). This shap has the advantage that the air affects the cake on al sides and develops therefore a very intense heat. The mould grate was at first installed in English furnaces, but is in use also in other systems, as *e.g.* in Humboldt's.

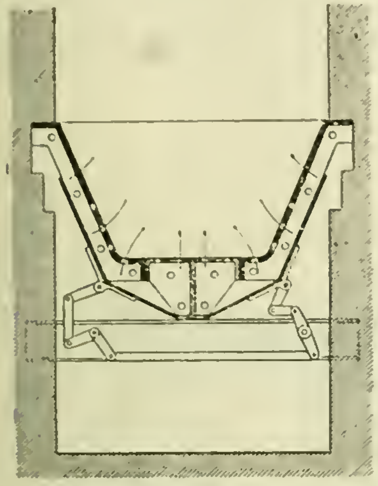

Fig. 3.—Mould Grate.

The English furnaces have not adopted from Herbertz the small cells and the manifold individual feeding devices, but remain of the same large capacity of 20 to 24 tons in order to save wages. Since the cake became consequently too heavy, mechanical discharge was introduced, for which the mould-shaped grate is admirably suited, because the clinker on account of the intense heat vitrifies well and takes the form of a mould and can be removed as a whole. The handling of the clinker is facilitated to the operator by the use of a bar generally bent to a spiral shape, which is put into the refuse and around which the clinker melts. By means of a ring-shaped handle attached to the spiral iron bar the whole cake can be removed by a winch without any trouble. This device is patented by Heenan and Froude (Fig. 4).

With the aid of this device the difficulty of enlarging the cells was removed and mechanical removal was adopted. Thus four cells in Frankfort a/M. have been replaced by two of double the size, and the daily capacity of 25·30 tons of a group of cells could be increased to 40—50 tons dealt with in two large cells. The temperature is likewise essentially higher than in the old Herbertz type.

The above traces briefly the evolution of the so-called hearth furnaces up to the present time. English and German firms have come to the same conclusions by different paths. Although Herbertz has not given up the independence of the unit cell as in the English furnaces, the result in both systems is the same, namely, a cell of 2·4—3·0 sq. yds. area and a capacity of 20—25 tons per 24 hours.

The evolution of the hearth furnace has reached its limit. Further increase of capacity per square yard of grate area, not possible on account of the small charging height, would necessitate a still greater draught and further, with charging in thin layers, the draught would penetrate only in some places, so that unconsumed coal and superfluous air would result, especially if the refuse is not carefully distributed. This distribution work becomes again more difficult in large grates, recently recommended as more advantageous.

The large amount of vegetable ingredients suggested the idea of gasifying the refuse. With the great charging height of such gasifiers of about 1·1 yd., the distribution of draught is easier because the air has a better opportunity to mix with the coal and to promote more perfect combustion. The upper layer of refuse can dry without withdrawing too much heat from the combustion centre

The best generator of gas is the blast furnace, and on this principle Dr. Dörr designed his incinerator, which was erected at Wiesbaden. It consists simply of a shaft of fireproof masonry which is constantly filled with refuse. The air is forced into a front channel at the bottom of the shaft and passes at a high velocity through the clinker, which is withdrawn at the front (Fig. 5).

The refuse gasifier of Dörr was a badly constructed gas generator. In every shaft furnace, the air tends to rise along the walls while the mass in the centre remains unburnt. By forcing draught through the front channel the air escapes by the shortest route. This means the draught ascends on the front wall and does not affect the refuse

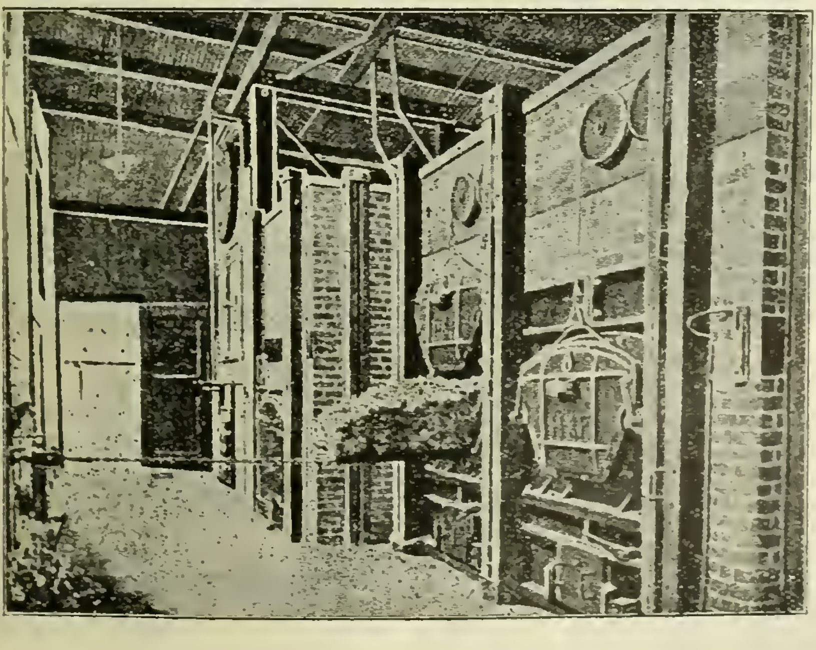

Fig. 4.—Heenan-Froude Discharger.

at the rear of the furnace, thus leaving it in an imperfect state of combustion.

The failure of this was proved by Dr. Ing. Meyer in a series of experiments conducted at Wiesbaden and Kiel, on destructors of the Dörr and Herbertz type, the results of which are shown in Table I. (p. 388). It will be noticed that the composition of smoke gases of Dörr was fairly good; the small excess of air proves that the combustion in the Dörr furnace left nothing to be desired. The temperatures attained were likewise favourable. If in face of this the resultant effect of the Dörr furnace amounted only to 41 per cent. against 66·5 per cent. in the Herbertz furnace, the reason for this may easily be found in the loss of unburnt coal in the clinker which amounts to 40 per cent. with Dörr's against 10·8 per cent. with Herbertz's furnace. This fact proves that with Dörr's system the combustion only occurred in the front part of the shaft, while the refuse at the rear was removed in an unburnt state.

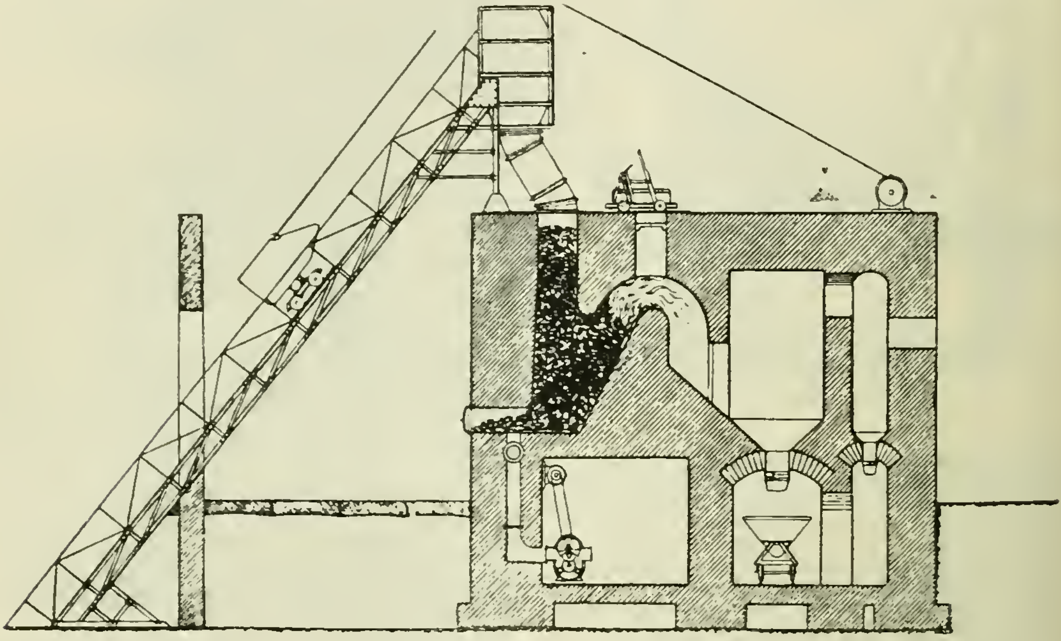

Fig. 5.—The Dorr Incinerator.

The table shows other interesting features. Besides the loss of unburnt coal, there are also losses by radiation and of heat carried away with the clinker. However, it is obvious from these experiments that the amount of heat remaining in the clinker when drawn from the grate is a negligible quantity, thus proving that Humboldt is incorrect in his statement of the value of clinker heat for heating air which he claims to be the advantage of his system. The clinker heat in both systems is nearly equal and amounts only to 3·4 and 3·5 per cent. respectively.

The loss by radiation amounts in the Dörr furnace to 15·6 per cent., and in the Herbertz furnace to 19·2 per cent. In both systems this loss could be reduced, although it is always an advantage in the shaft furnace to keep the heat more concentrated, and its radiating surfaces are much smaller than those in hearth furnaces.

Recently the tendency has been to do away with the constructive failures of the Dörr furnace and to borrow ideas from the blast furnace and the modern gas generator; particularly is this the case as regards the circular shafts which can be charged much more easily than rectangular ones. The air is forced in either centrally or, as in the blast furnace, radially through jets.

Further, it had been necessary with the introduction of gasification of refuse to cool the walls of the furnace because the clinker easily adheres to a hot wall. Dr. Dörr considered that a firebrick wall with a cavity would obviate this difficulty. But this did not prove to be the case, as the temperature in the cavity could not be reduced sufficiently. Thus the water-cooled jacket was introduced.

Improved means for discharge were also attempted. The discharge in gas generators for coal is done mechanically by a kind of eccentric which ejects the cinders continuously over the sides directly into wagons. It seems doubtful whether this device can be adopted in the same way for the discharge of refuse clinker. However, meanwhile a destructor had been constructed by Didier at Wiesbaden which had all these features of a cooled shaft and which performed the discharge by a knife-edge which cut off the clinker, removing it thus downwards without disturbing the service of the real gasifier in the upper part.

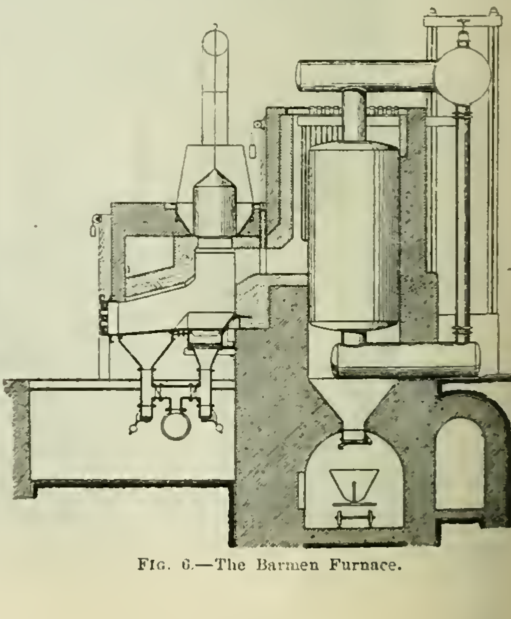

Fig. 6.—The Barmen Furnace.

Whether it is right to encourage a continuous gasification as is done in Didier's furnace or to burn down periodically several charges remains to be proved. Each combustion of refuse shows three phases: the first is the evaporation of water and the heating of the refuse up to 100° C., the second is the escape of products of distillation up to 500° C., and the third is the gasification of the remaining carbon. Only the last process generates heat and produces all heat including that for the formation of clinker. With the continuous gasification the danger is that the simultaneous evaporation of water withdraws too much heat from the hearth and a mean temperature results which suffices to gasify the refuse but which is probably insufficient to vitrify the clinker. For each charge it is simpler in practice first to evaporate the water and finally to burn the dried refuse, so that in the last phase of the process the full development of heat is not influenced by any other process consuming heat.

Meanwhile, the Hamburg management had noticed that in the charge of the Horsfall furnaces, lasting 1½ hours, the second half of this period represented only a current of air passing principally through ashes. Therefore the furnace was charged hourly for experiment. The result of this operation reduced the cooling losses and the excess of air considerably. Five minutes after charging the maximum temperature, 1150° C. was reached, while it was formerly difficult to reach 1000° C. The method of operation in the Horsfall furnace, however, required too many operators owing to the height (referring to Fig. 1) from the grate to the crown being so low that the difficulty of uneven distribution of draught increased with the increasing air pressure.

A further increase of efficiency was accordingly only possible by means of a greater height of the crown, *e.g.*, by shaft furnaces similar to a blast furnace. The result of this difficulty was the invention of a special type of furnace at Hamburg in 1904. For a grating a perforated iron sheet was chosen. The furnace itself was constructed in a rectangular form, the upper part of which was of a fustrum of a pyramid, and a double bell trap was used for charging. In order to attain an equal distribution of refuse the corners of the shaft were oblique so that the plan was octagonal. The hearth itself remained rectangular and was water-jacketed for cooling purposes. Against this the objection is often raised that water-cooling deprives the furnace of heat to a certain extent; although recent styles of incinerators with a water-cooling jacket have been more generally adopted because it is safer for the operation as the clinker does not adhere to the walls and is more radical. The loss of heat in shaft furnaces serving for the gasification of coal is approximately 3 to 4 per cent.; on the other hand the effluent from the jackets may be used for feeding a boiler or other purposes.

This furnace burnt successfully in permanent operation 31 tons of refuse. The mean temperature was 1050° C.; the amount of CO_2 reached 18—20 per cent. after each charge.

The principle of the Hamburg furnace was adopted by the City of Barmen, where a similar furnace was designed, distinguished by a divided grate; this has been tried in other places as well as in Hamburg. In 1903 a furnace was built in Stockholm (Sweden) which deserves notice for its peculiarity. The refuse falls into a high shaft which is closed below by an oblique grate, from which the clinker cake is drawn on to a similar inclined preliminary grate in order to burn here completely and to give off its gases through a preliminary chamber and openings in the partition wall into the combustion shaft proper. The practice of using the heat of the hot clinker was likewise applied to the Barmen furnace (Fig. 6). Here also the proper combustion chamber is a high shaft which shows exactly the Hamburg feature; the feeding is done by a double bell as in Hamburg, and the grate is also similar. In the front of this a preliminary grate is provided similar to the one previously used in Stockholm, on to which the clinker cake is drawn after 20 minutes, so as to provide heat to the incoming air which is to serve as highly heated secondary draught for combustion of CO formed in the furnace proper. As already stated, the amount of clinker-heat is very slight, and this furnace may work with it or without. It is immaterial whether the clinker is drawn on to the pre-grate after 20 minutes or whether it remains on it for 40 minutes. The system was recently introduced by the City of Fürth (Germany) and is designated as the Humboldt system (Fig. 7).

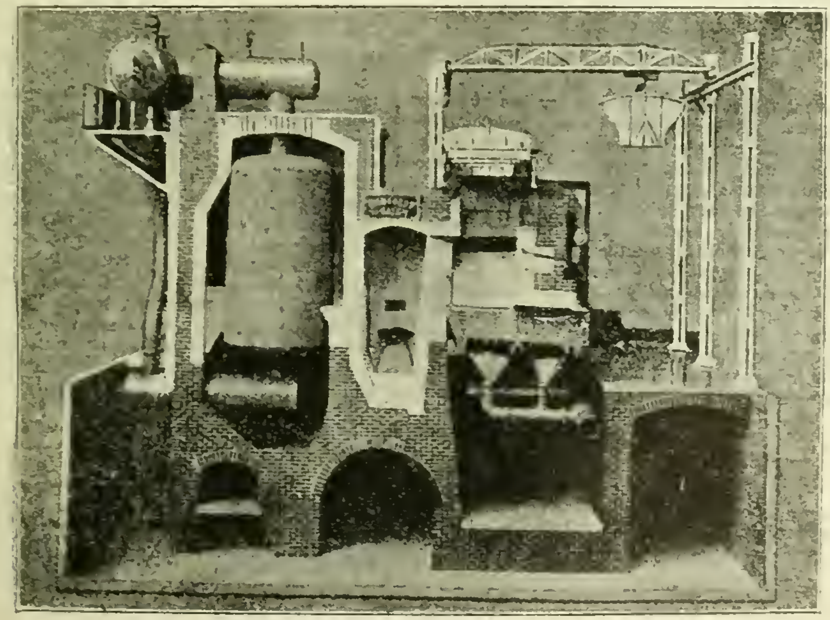

Fig. 7—Humboldt System.

The engineers of the Horsfall Co. have also followed the evolution of the Hamburg furnaces and have adopted its system of direct feeding and the perforated grate, so that practically from 1905 the old pre-drying hearth has disappeared even in the English types.

In the whole of these systems working with thin layers, manual labour is necessary to distribute the refuse uniformly over the grates, thus proving the advantage of the shaft furnace which can be worked mechanically.

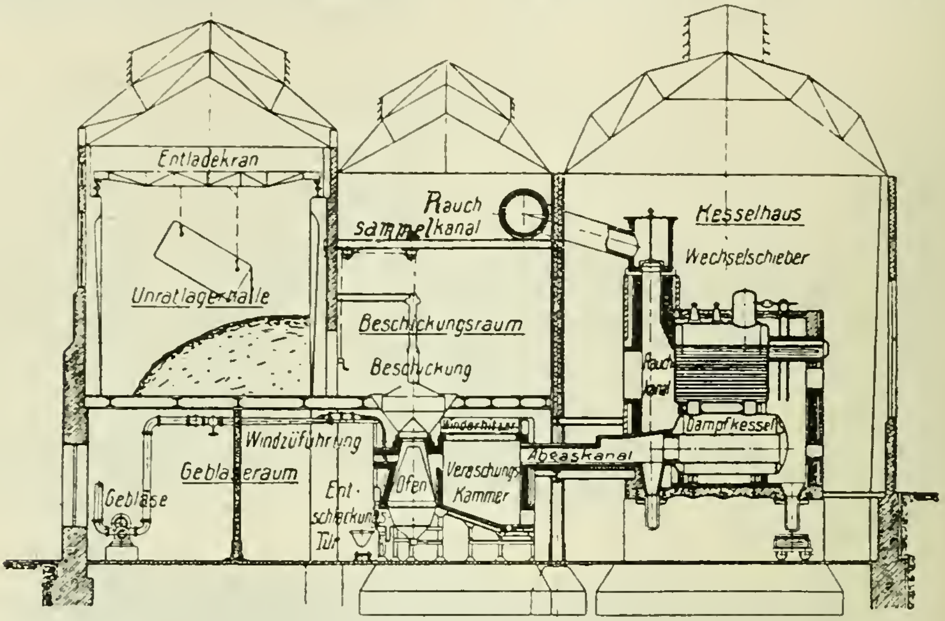

Fig. 8.—Hamburg Furnace.

In the meantime the Hamburg furnace has been further improved. Here especially it has been recognised that the evaporation of water retards the ignition and thus the combustion accordingly reduces the efficiency of the furnace. To counteract the period of cooling the principle of the blast furnace has been adopted, by which the combustion air is previously heated. This has been done in some types by installing a superheater system by means of boilers connected with the furnace. But as these boiler gases ought normally to have a maximum temperature of 250° C. the heat gradient is much too small to attain an effective preheating. On the other hand the whole benefit of heat is not obtained by the boiler if wet or inferior refuse is consumed. In this particular case preliminary heating of the air is essential. Here also the blast furnace has shown the way. The air heaters were placed at the hottest point in the system, that is in the combustion chamber, and so it is possible to attain temperatures of 350° C. in the combustion air.

The adherents of other systems have acknowledged the importance of high air-heating. Dörr has calculated for medium garbage of 15 per cent. water and 66·4 per cent. residue, that with double the amount of air necessary for good combustion, a temperature of only 1150° C. can be obtained, whereas with air heated to 300° C. a temperature of 1530° C. is produced. Without this preheating such refuse would probably no longer produce useful clinker and pre-heating is of much more importance on wet refuse.

The most important results of air heating are quicker ignition, the accelerated combustion of the refuse and an increase of the furnace efficiency. The Hamburg furnace of 1·4 sq. yds. grate area consumes in 24 hours in a normal average 37 tons and 44 tons of refuse at a maximum rate.

The charging takes place at Hamburg by the double bell trap (Fig. 8). Two cranes lift the body of the wagons

in which the refuse is collected and dump the contents on a large platform whence the refuse is conveyed in wheelbarrows to a feeding stage adjoining the platform. At first the circular trough between the exterior bell and the hopper-shaped opening of the furnace is filled. By lifting the bell the refuse drops into the funnel and the outer bell is closed. The inner bell is then raised and the refuse falls on to the grate so that the furnace is never actually open. The charging by hand was retained here on account of the existing haulage method, and a further reason was that Hamburg would not abandon this system as shells and other explosive matter have frequently been found in the waste and accidents have occurred. A third reason was the extremely varying composition of the Hamburg garbage, in which big pieces exist up to 1 yard long, which would require large buckets. Experiments with such a construction had but unfavourable results.

However, there is no reason to continue the charging by the double bell method, which is used exclusively in the blast-furnace with bucket feeding, or to empty the wagon-bodies directly into the mouth of the bell as it is done with the Ochsner system (see Fig. 7).

The Hamburg plant is at present not in a position to sell steam or electric power like other incinerator plants. Still a considerable revenue appears in the annual reports from the sale of the slag, which has proved to be valuable as a substitute for gravel in mixing concrete or as a filling material for road construction and covering old dumping grounds.

A concise idea of the costs and efficiency of the various types can be obtained from Tables II. and III.

From the above it will be seen clearly that an incinerator should be of the simplest and most efficient type, and of the lowest cost, which is without doubt that of the shaft furnace.

PROF. E. C. C. BALY IN THE CHAIR.

COAL AND THE CHEMISTRY OF ITS CARBONISATION.

BY JOHN HARGER, M.SC., PH.D. M.INST.M.E.

VERY little is known of the chemical composition of the various constituents of coals though some progress has been made by various workers in separating them by the solvent action of pyridine, as discovered by Professor P. Bedson. Some coals, such as anthracite, semi-anthracite, and steam coals, yield very little pyridine-soluble matter, neither do brown coals nor cannels yield very much, but some bituminous coals give as much as 40 per cent. extract. The utility of the pyridine extraction method is however impaired by the facts that the ultimate chemical analyses of the soluble and insoluble portions from the same bituminous coal differ very little, and that, up to now, all the fractions contain more nitrogen than the original coal, indicating that some pyridine, in spite of all the precautions employed to remove it, has been retained by the coal substances. By the usual Soxhlet method the quantity slowly dissolved by pyridine is large at first, then more is dissolved very slowly indeed. An extraction usually extends over two weeks at least.

The author has lately found that a better method is to take a small quantity of the finely powdered coal (passing through 120 mesh sieve), say about one gram, add 150 grams of pyridine, seal in a strong glass tube and heat to about 160-180° C. for twenty-four hours. By this method more extract is obtained in twenty-four hours than by the usual method in months.

The chemists at the Government Experimental Station at Eskmeals have found that the inflammability of coal-dust is in proportion to the quantity soluble in pyridine. The French Government chemists, however, have found that, for French coals at least, this relation does not apply. The author has found that cannel coal contains very much less soluble in pyridine than ordinary bituminous coals, *e.g.*, by the Soxhlet method. Old Roundwood cannel yields 15½ per cent. and Lancashire Arley coal 22½ per cent., yet there is no doubt whatever that the cannel dust is far more inflammable than the dust of the Arley coal, each of the same degree of fineness. It was found, however, that Arley coal dust, which gave only 22½ per cent. soluble in pyridine by two weeks' extraction in the Soxhlet, gave 40½ per cent. soluble in pyridine by the sealed tube method. 150 grams of a different sample of Arley coal, but taken from the same mine, was extracted first by chloroform and then by several portions of pyridine, boiling up in each case for a long time until only a trace of soluble matter was obtained. A portion of the residue was then taken and heated in a sealed tube for thirty-four hours at 161—180° C, and the residue from this heated with a fresh portion of pyridine for twenty-four hours at 160—180° C with the following results, stated on the dry and ash-free substance :—

Some of these fractions were saturated with chlorine, after removal of pyridine, etc., in a current of inert gas at 150° C., and the increase in weight is stated below. Chlorine and hydrochloric acid were removed *in vacuo* over sodium hydroxide.

Increase in weight, per cent., Fraction B, 74·4 ; C 64·4 ; E 55·7 ; F 31 ; H 64·2.

A considerable number of experiments have been made on the action of chlorine at high temperatures. CH_3Cl, CH_2Cl_2, $CHCl_3$, CCl_4 and C_2Cl_6 in considerable quantities were obtained, but further experiments are being made which will be reported later.

The fact that pyridine dissolves the so-called resin bodies so very slowly and dissolves much more with the slight increase in temperature by the sealed tube method, shows that this is not a case of ordinary solution. The extract once obtained is quite readily soluble in pyridine and gives a thick, viscid, tar-like mass, and that it is not "absorbed" by the insoluble portion of coal is shown by examination of thin sections which show the resinous bands and nodules to be separate from the general matrix.

There appears to be some kind of simplification in the constitution of the constituents which yield the pyridine soluble matter, a process similar to depolymerisation and due to the action of pyridine and heat. This is similar to the behaviour of many ordinary resins which are only soluble in certain solvents after they have been heated at moderately high temperatures for some time. Clark and Wheeler* have shown that the pyridine extract from silkstone coal can be separated into two fractions by the solvent action of chloroform, and the author has found that this is the case with the pyridine extract from Arley coal also. The solution by chloroform is an extremely slow process and requires about two weeks to make the extraction complete. This points to either absorption or depolymerisation.

An interesting point is that this chloroform soluble portion does not appear to be in the original coal as such. There is some portion of Arley coal soluble in chloroform and the quantity seems to vary very much with coal

Ultimate Analysis	Carbon	82·92	80·81	82·80	81·26	— 1·66	77·32	85·33	80·52	— 2·37
	Hydrogen	5·58	5·23	7·14	5·61	+ ·03	5·14	7·08	5·91	— 1·23
	Oxygen	8·45	10·40	6·62	9·64	+ 1·19	14·26	4·56	10·38	+ 3·76
	Nitrogen	1·31	2·14	1·91	2·09	+ ·74	2·07	1·71	1·92	+ ·01
	Sulphur	1·70	1·42	1·44	1·42	— ·28	1·21	1·32	1·25	— ·19

even from the same seam. In one experiment it was as much as 3·9 per cent. but generally it did not exceed 1½ per cent. This substance contained no sulphur and no nitrogen and gave on analysis, hydrogen, 8·81 per cent., carbon, 83·92 per cent., oxygen, 7·27 per cent.

The portion dissolved out of the pyridine extract by chloroform was rather more than one-third of the total pyridine extract, and this material contained nitrogen and sulphur as well as carbon, hydrogen, and oxygen.

In the paper by Clark and Wheeler results of extraction of silkstone coal (Altoft's Colliery) by pyridine, and subsequent action of chloroform on the extract obtained, are given with analyses of the various fractions. From their figures it is evident that all fractions contain more nitrogen than the original coal, and it appears on calculation that pyridine amounting to 4 per cent. on the coal taken has been retained by the fractions. Examination of their figures also shows (assuming the analyses to be correct) that in the extraction by pyridine and subsequently by chloroform a considerable quantity of oxygen has been absorbed and some sulphur lost.

These figures show that :—

(1) 100 parts of coal have retained slightly more than 4 per cent. of pyridine.

(2) Oxidation has occurred in both extractions, but especially with chloroform, where the oxygen has increased by nearly 60 per cent.

(3) There is loss of sulphur in both extractions.

It might be gathered from these figures that the absorption of oxygen is an essential feature in the solution of these constituents by pyridine and chloroform, but the fact that more is dissolved by treatment in a sealed tube in absence of air proves that this is not so.

The fact that pyridine is retained by the fractions even after heating in vacuo at 100° for several days has been proved by heating a portion of pyridine extract in a current of nitrogen at 150° C. The gas which came off contained pyridine, and was passed through H_2SO_4, which was distilled later with potash and the distillate titrated. This experiment showed the presence of 3·7 per cent. of pyridine in the material. Later experiments have shown that the portion insoluble in pyridine contained pyridine after heating in vacuo for several days at 100° C, and it has been found much more difficult to remove all the pyridine from the insoluble than from the soluble fractions.

The coking property.

Not every coal gives a satisfactory coke on carbonisation. A coal which will coke must contain a certain minimum quantity of bituminous matter. Coals like anthracite and semi-anthracite do not coke nor do the tertiary coals—lignites and brown coals. The coals selected for making metallurgical coke contain sufficient bituminous matter to fuse on heating to a few degrees above 310° C. The mass of washed coal is converted on heating to a pasty mass, from which, on further heating, the volatile matters distil, leaving a fixed carbonaceous residue which becomes harder and stronger the higher the temperature employed because volatile hydrocarbons are decomposed, with deposition of carbon, in proportion to the temperature of the solid material through which these volatile hydrocarbons have to pass. With very high temperatures the product is hard and will withstand considerable pressure.

It appears that the coking properties of coals must be due to some compounds of C, H, O, N, and S, about which little further is known than that they melt at about 320° C. Anderson and Roberts[*] showed that coals of the Clyde Basin began to soften at 310° C and melted fairly completely at 320° C. The best coking coals melted at 317° C. The older coals coked, the newer ones did not.

	Carbon.	Hydrogen.	Oxygen, etc.	Coking power.
on-coking	82·65	5·55	10·1	3·9
emi coking	83·16	5·48	8·98	4·1
oking	85·41	5·36	7·22	13·5

It is not possible to tell from the ultimate analysis of a coal whether it will coke, but it is often found possible to say that it will *not* coke. Cases are known of coals of exactly the same ultimate chemical composition some of which coked quite well and the others not at all. An essential part of the process of coking takes place between 250° C. and 400° C. If coking coal is carbonised below 400° C., then powdered and heated to very high temperatures such as are employed in metallurgical coke ovens, there is no sign of sticking together of the particles. It is generally believed that it is the quantity of the so-called resinous constituents in coal which determines its coking or non-coking property. According to Anderson this has been proved to be wrong, but on what evidence is not clear. A study of his papers reveals no facts supporting this conclusion.

Some of the fundamental facts about the coking property are :—

1. The coking property in some coals is destroyed by exposure to air, and even in more strongly coking coals it is sensibly diminished.

2. The coking property in some coals is destroyed, in others weakened and in some not affected by boiling with dilute caustic potash.[*]

3. Heating in a current of inert gas at 300° C. for several hours destroys the coking power of some coals and weakens it in all coking coals. The strongly coking coals, however, retain sufficient to coke when strongly heated.

Anderson and Roberts conclude, and Professor V. B. Lewes agrees, that on these facts strongly coking coals, in addition to the so-called resin bodies, contain a class of substances which are not soluble in alkali, do not oxidise in warm air and do not decompose or volatilise at 300° C., and that substances of this class melt on strongly heating and yield enough luting material to form coke. They call the substances of this class the "hydrocarbon bodies." The assumption or deduction of the existence of a class of compounds in coal called hydrocarbons, on such evidence, is not, in the author's view, justifiable and they must be omitted from the constituents of coals. (Hydrocarbons have been found only in mere traces in coals.)

The phenomena described above would be observed if the so-called resin and other bodies on slow heating, etc., decomposed and yielded, amongst other products, a *smaller* quantity of a substance which was fusible at higher temperature, and this is what the author has found does actually take place. The true coking coals contain sufficient resin-like bodies to yield, after heating at about 300° C., sufficient fusible material to form coke when heated to 320° C. or above. While the feebly coking coals on heating, etc., gave the same kind and proportion of fusible bodies, the quantity was not sufficient to melt or render liquid the whole of the material and so coke could not be formed.

A sample of Arley coal extracted with chloroform gave 1·2 per cent. soluble ; on heating another portion of the coal to 230° C. in inert gas for five hours it gave on extraction 1·4 per cent. soluble in chloroform. A third portion, heated for five hours at 270° C., gave on extraction 7·6 per cent. soluble in chloroform. A fourth portion was alternately heated to 330°—340° C. in inert gas, and extracted with chloroform five times ; the total time of heating was twenty-two hours, and the total of the chloroform extracts amounted to 8½ per cent. on the original coal. It is evident that a subtle change starts in Arley coal at about 250° C. and at 270° C. it is very marked, although the coal is changed very slightly in appearance and no permanent gas appears to be evolved. Experiments were made to ascertain which part of the coal gave rise to these products soluble in chloroform. Pyridine extract after heating to 340° C. gave 8·2 per cent., and pyridine residue after similar treatment gave 1·6 per cent. It is therefore evident that both constituents give rise to the products.

Nitrogen in coal.

There is evidence to show that nitrogen occurs in coal combined in two or more essentially different ways. A small quantity of the total is given off as ammonia on carbonisation, whilst half of it remains in the coke, indicating that it occurs in coal combined in at least two different ways and probably more.

---

[*] See this Journal, 1898, 1013—1020.

[*] Anderson and Roberts, *loc. cit.*

It has been observed that in some coals the amount of nitrogen estimated by the Kjeldahl method is a mere trace, when a Dumas estimation reveals the fact that there is about 2 per cent. In other coals the two methods show exactly the same amount, showing that the nitrogen is not held in a similar way in all coals. It has been further observed that when some coals are mixed with caustic soda and ignited much less nitrogen remains fixed in the residue after carbonisation than in the residue of the untreated coal, and, on the contrary, it has been observed that other coals, when treated in a similar way with caustic soda, etc., had more of their nitrogen fixed than when heated alone.

Some of the fixed nitrogen can be converted into ammonia by passing hydrogen over the red-hot coke, but the only practical method hitherto devised of increasing the yield of ammonia is to burn the coke while keeping the temperature as low as possible, as in the Mond producers.

The nitrogen which comes off as ammonia on the carbonisation of coal probably exists in side-chain groups whilst that which remains fixed in the coke probably occurs in ring compounds, the ring part being stable at a red heat.

Over twenty years ago R. J. Friswell discovered that by acting on powdered coal with nitric acid of about 50 per cent. strength, a complex organic acid or acids were obtained, which decomposed sodium carbonate with evolution of carbon dioxide. These bodies, which were later called the coal acids by Anderson, are insoluble in water containing much mineral acid but in pure water or dilute alkali or dilute acid they are soluble, giving an ink-like solution. The solid coal acids on heating with zinc dust gave hydrogen, cyanogen, and a small quantity of aqueous distillate, smelling of ammonia and pyridine and containing hydrocyanic acid (Friswell).

Anderson worked on compounds, made from very different kinds of coals by treating with nitric acid, and found that the resulting coal acids had about the same ultimate chemical composition. It seemed probable that the nitric acid oxidised all the side-chains, giving COOH groups attached to a nitrogen ring complex. To test this the author oxidised some Arley coal with fuming sulphuric acid (so as to keep nitrogen containing reagents out of the experiments) and obtained similar compounds to those got by Friswell and by Anderson. The solid purified coal acid was mixed with caustic soda and heated. A gas smelling like charred albumen or bone was obtained, and the same was obtained several times on repeating the experiment with fresh quantities of coal. This would appear to indicate that coal contains nitrogen in the form of a ring complex, which on oxidation with fuming sulphuric acid is converted into a carboxylic acridine.

The old and modern Coalite processes were described by the author. In the modern process the coal is carbonised at about 650° C. with the result that the fuel is not so friable. The yield of sulphate is raised from 12 lb. to 28 lb., the tar is reduced to 18 gallons and the gas increased to 8,500 cubic feet per ton of an average bituminous coal. He also referred to low temperature carbonisation *in vacuo*, and pointed out that as much as 80 to 100 gallons of coal oils were obtainable from certain cannel coals by this process, a considerabe portion of which could be converted into petrol (8 to 10 gallons) and a large proportion of the remainder into oils suitable for use in Diesel engines. Another low temperature carbonisation process, viz., the "Del Monte," was briefly mentioned.

None of these processes was intended to replace either gas-works practice or the metallurgical coke ovens, and the author questions whether, in view of the demand for a smokeless fuel and the great advance in the value of petrol and oil suitable for Diesel engines, the modern gas-works practice of obtaining as much gas as possible per ton of coal had not been overdone, and the old lower temperature carbonisation was not more suitable to present needs.

As regards metallurgical coke it was also a question whether this could not be produced in two stages, viz. :—

(1) Carbonisation at a sufficiently low temperature to preserve the valuable light oils and give rich gas, and (2) High temperature carbonisation to give the finished hard coke and poor gas.

Both the gas-works manager and the coke-oven manager could learn from the study of big gob-fires that, under certain conditions, it was not a question of how difficult it was to heat up coal, but how difficult it was to prevent it heating up spontaneously. Also that a gob-fire could give a beautiful hard coke with coal which no existing coke-oven process could coke at all.

Practically any bituminous coal could be coked in favourable circumstances, but ordinary coke-oven processes did not give these favourable conditions.

1914.

PROF. E. C. C. BALY, F.R.S., IN THE CHAIR.

PREDICTION AND INVENTION IN CHEMISTRY.

BY H. E. POTTS, M.SC., CHARTERED PATENT AGENT.

This paper deals with the antithesis between prediction and invention in chemistry ; first, the nature of invention, and second, the possibility of prediction. For this purpose we must consider the manner in which modern chemical technology evolves and differentiate this evolution in order to display two distinct types of factors which contribute to it. One of these types includes continuous improvements such as may result from the exercise of skilled workmanship or good judgment, from the satisfaction of local requirements, or from the dictates of convenience or necessity. The other of these types includes what are denoted "inventions." An invention represents a discontinuous advance, a sudden change, even though it may be a small one. Such a discontinuous technological variation may result from a fortunate accident, from careful experiment, from keen observation, from a happy thought, or from the concentration of an intellect far more powerful than the average. Any of these causes may give birth to an improvement which somehow differs from the other type of improvement arising from skilled workmanship, and we may express this difference by saying that discontinuous improvement is an invention.

Technology may advance by improvements in degree, which are not inventions, and by improvements in kind, which are inventions, but this sentence would give an erroneous impression if read apart from what follows.

An American authority, Professor Robinson, has expressed the difference by saying that an invention involves the exercise of the creative, as opposed to the imitative, faculties of the mind. This is well put, but it does not take us much further, since it calls for a definition of the word "creative."

From the legal point of view an invention is a advance in technology which is capable of forming th subject-matter for a patent. For over a century it ha been recognised that the principle upon which the Crow grants patents resembles that of an ordinary contract The inventor comes forward with an invention and put the public in full possession of it. In return, the Crow grants him a monopoly of its exercise for the term o fourteen years.

There are certain conditions attached to the contract If the inventor is to receive a reward he must give the publi a real something which was not before in their possessio and that something must be useful to the public. It is n every improvement in technology which can form th subject-matter of a patent, since if this were so industri advance would be unduly hampered, because peop would be prevented from making the slightest modificati in what they had been doing previously. For instanc it would have been ridiculous if, by means of the Pate Law, manufacturers could have been prevented fro using plantation rubber for the various purposes f which they had previously used Para rubber, even thou its substitution might effect an improvement in the direction of reducing expense. Clearly, therefore, in granting and in upholding patents the law must draw a distinction somewhere between the various kinds of improvements. In this way, we may assume that there is a possibility of discriminating by considering industrial advance as made up of improvements belonging to either the continuous or discontinuous type.

It is often difficult to draw any such sharp distinction between these antithetic types. This may be illustrated by one or two parallel cases in chemistry. For example, how are we to draw a definite line between acids and bases in presence of the class of amphoteric substances, which form a perfect and uninterrupted transition from acids to bases? Similarly, in spite of the wide difference between them, the aliphatic and aromatic bodies are linked by the hydro-aromatic compounds and the various polymethylene rings. Again, there is the transition from a typical crystalloid such as salt to a typical colloid such as gold hydrosol through solutions of substances possessing a very high molecular weight and lying upon the border line.

The same tendency may be found in nearly all scientific investigation. As Pater well remarked :—" The sciences of observation . . . reveal types of life evanescing into each other by inexpressible refinements of change. Things pass into their opposites by accumulation of undefinable qualities."

From a chemical point of view these cases on the border line are of great theoretical interest and do not present serious difficulties. We content ourselves by saying that an amino acid, for instance, is an amphoteric substance, and we thus create a third class intermediate between acids and bases.

In legal matters this easy solution is impracticable. When invoked to decide the validity of a patent, the law must hold that it is either valid or invalid, and no intermediate decision is normally possible. Hence, for legal purposes, it is necessary to throw considerable emphasis upon distinctions such as those I have mentioned above, in order to give us some criterion which will enable the dividing line to be drawn. While, therefore, in the abstract it may be true enough that *all* differences are differences of degree, that is, continuous, and not of kind, that is discontinuous, it is as well to bear in mind a fragment on " Differences " in Butler's Note Books, in which he says :—" This in theory ; but in practice it would get us into such a mess that we had better go on talking of differences of kind as well as degree." In what follows, therefore, I will assume that it is essential for legal purposes to mark out two different classes of improvements which must be kept mentally distinct from one another as far as possible.

We will assume that the improvement in question is new, in the sense of being different from what has gone before. Extremely subtle points may arise in this connection which are outside the scope of the present paper ; it will be sufficient to give two examples.

The American case Libbey *v.* The Mount Washington Glass Co. dealt with an invention arising out of an old process of making articles of glass-ware of a ruby colour from a well-known glass mixture containing gold, from which mixture a ruby colour used to be obtained by reheating the glass.

The patentee discovered that if portions only of the glass were reheated it was possible to obtain an article exhibiting both amber and gold colours to any desired extent. It was shown that accidents had taken place previously in preparing the ruby glass so that occasionally portions remained of an amber colour ; in these cases however the articles were spoilt and no one thought of utilising them. Under these circumstances such spoilt articles accidentally produced and rejected were not anticipations of commercial products of great beauty, prepared according to the reasoned application of the process of reheating in parts.

For another example we may turn to the litigation involving the Flour Oxidising Processes. It had long been known that flour was bleached naturally on prolonged storage with exposure to air, but Andrews showed that rapid and satisfactory results could be attained artificially by subjecting the flour to the action of air containing small quantities of nitrogen peroxide.

It was argued that this process was anticipated by a previous patent which had unsuccessfully proposed to bleach flour artificially by subjecting it to the action of an electric discharge. Now it is well known that nitrogen peroxide can be produced from air by sparking.

This contention however was unsuccessful because nitrogen peroxide is only produced to any appreciable extent by a spark discharge in contra-distinction to a brush or a silent discharge, both of which produce ozone. The previous patentee did not state that a spark discharge rather than a brush discharge was to be employed and therefore he did not give information leading to the essential condition for practical success, namely, that bleaching must be effected by nitrogen peroxide instead of ozone.

Unless therefore the previous patentee could prove that he actually had used his apparatus so as to give a spark discharge rather than a brush discharge, he had not anticipated Andrews. He was unable to bring such evidence and therefore Andrews' patent for bleaching by the use of nitrogen peroxide was held to be not anticipated by a previous apparatus which *might* have been used so as to achieve this object.

How are we to determine whether an improvement which differs qualitatively from what has gone before, differs sufficiently to justify us in terming it an invention? Seeing that invention involves a certain discontinuity, in many chemical cases we can arrive at some estimate as to whether such discontinuity exists, by examining whether it would have been possible to predict the improvement or its result beforehand, without making experiments.

In many chemical cases prediction and want of invention are synonymous terms but there are other cases to which this does not seem to apply at all. In mechanical cases it seems usually quite inapplicable. Moreover everything depends upon the exact use we make of the term prediction.

A chemical industrial process obeys certain laws and it will not usually be an invention to modify or improve a process by the *mere* application of well-known chemical laws. For this purpose, we will take a number of these laws, giving a parallel series of examples of unpatentable, and of patentable inventions.

(1) One of the simplest examples is the *additive law* according to which the properties of a mixture of $A+B$ can be predicted from a knowledge of the properties of the separate constituents A and B. Some time ago it occurred to me that in view of the difference in price, it might be worth while to make crucibles of a mixture of platinum and gold, thus obtaining a metal which would be cheaper than platinum but yet stronger than gold. Now assuming that it is known to manufacture alloys of platinum and gold, it may be said that there is no invention in making crucibles of such an alloy since the properties of such crucibles would at once be predicted from the additive law.

We might generalise this statement by saying that in cases where the *law of continuity* applies, there is generally no invention in interpolating between known limits or extrapolating beyond known limits, even though no one had previously done precisely the same thing before, provided that no unexpected result is produced.

(2) Again in many cases there is no invention in simply applying the *law of mass action* to a chemical reaction. Suppose that a manufacturer is preparing the ester of an expensive organic acid with a certain alcohol. If the price of the alcohol suddenly rises there will be no invention in applying the law of mass action by using an excess of acid so as to reduce the loss of alcohol at the expense of the acid which has now become cheaper. This result could have been predicted beforehand and the process is clearly not patentable.

Similar considerations apply in lixiviation where the amount of substance extracted, *e.g.*, sugar from cane, will depend on the price of fuel, and the maximum theoretical efficiency of extraction will not be the most profitable. This, however, is usually a matter of business judgment not of invention.

(3) There are certain laws in connection with *reaction velocity.* It is generally known that the reaction velocity rises rapidly with increase of temperature and therefore no invention is involved in simply performing a reaction at a higher temperature; in normal cases the temperature chosen may be a matter of convenience depending upon the balance between the cost of fuel and the advantages gained by a high reaction velocity. In the absence of complicating factors therefore the application of this law is not invention even though it means that a manufacturer is doing something which may never have been done before.

(4) *Le Chatelier's principle* tells us that if the substances produced by a reaction occupy a smaller volume than the reacting substances themselves, the equilibrium will be shifted by pressure so as to produce more of the reaction-products. In connection with the condensation of isoprene to rubber, it occurred to me some time ago that the reaction would certainly be facilitated by pressure, but it may be taken as quite clear that the *mere* suggestion to raise the pressure is not patentable since the result is capable of prediction offhand. If a definite range of pressure were found by experiment within which a valuable result was obtained, the case would be different.

(5) Finally we have the *periodic law*, though predictions based upon this must be applied with caution. Speaking broadly, however, we may say that in the absence of special results there is no invention in substituting potash for soda or strontium for barium, etc.

I will now give examples in which the above laws are found to exhibit anomalies which would justify the grant of patents thereon.

(1) It is clear that the *additive law* does not hold for certain properties. For example the first person who discovered a useful eutectic might have made a valuable invention, although, at present this phenomenon of depression of the melting point is comprehended under another well known law. In cases where the additive law is not obeyed and an unexpected result is produced, the improvement will probably be an invention. For example, in the leading case of Muntz v. Foster, a patent was upheld for a sheathing for ships' bottoms composed of 60 parts of copper to 40 parts of zinc both in a very pure condition. As a result of this particular selection of proportions, it was found by exhaustive experiments that the metal could be rolled hot and especially that it oxidised just sufficiently to prevent the growth of barnacles and yet not sufficiently to cause rapid deterioration. Of course this result was very valuable, since if pure copper is used corrosion is very rapid whereas if plates of zinc were hung on to protect the copper by reason of selective attack, it was found that the copper became coated over with barnacles. Muntz' alloy just solved the difficulty and seeing that it was necessary not only to select certain proportions but also to employ very pure metals, it was held that his improvement was sufficiently novel and ingenious to support a patent.

(2) If it can be shown that a valuable result is attained which could not be predicted by the *law of mass action* the improvement will be an invention if novel. A good example of this will be found in the case mentioned by Prof. Haber in the Hurter Memorial Lecture. In producing formates from carbon-monoxide and caustic soda, it was discovered that a 10 per cent. solution of caustic soda gave much better results than other solutions, either stronger or more dilute. The reasons for this phenomenon do not appear to be understood even yet and we can therefore say without hesitation that this behaviour could not have been predicted, and that invention is involved.

(3) In connection with *reaction-velocity*, it will usually be an invention to accelerate the velocity by a suitable catalyte, if useful results are obtained thereby, since catalysis is at present outside the bounds of prediction. Hence the whole field of catalysis is a fruitful one for invention. Thus in the recent case of Crosfield v. Techno-Chemical Laboratories it was held that there was invention in applying to a liquid fatty acid, a process of catalytic reduction by hydrogen which had been applied to certain gases by Sabatier and Senderens. Although the action failed on other grounds it is quite clear that it was impossible in 1903, the date of the patent, to predict that catalytic reduction would be operative upon a liquid fat of fatty acid.

(4) Prof. Haber's researches give another interesting example of investigation originally based upon the *principle of Le Chatelier.* It would not involve invention merely to suggest that the equilibrium between nitrogen and hydrogen would be displaced towards the ammonia side by the employment of high pressures, but when we find that it was necessary to devise special apparatus, to correlate the temperatures and pressures, and to seek out appropriate catalytes for the various temperatures of reaction, we may certainly conclude that invention of the highest order is present. The fundamental conditions of success could not have been predicted from the mere application of the principle of Le Chatelier and the laws of reaction-velocity.

(5) The *periodic law* naturally presents many cases of deviations from strict regularity. More especially is this the case with the first members of the various groups such as lithium, whose chloride exhibits anomalous properties, or fluorine, whose silver salt is readily soluble in contra-distinction to the other halogen salts of silver. This behaviour therefore narrows the field in which prediction is possible; we may compare it with the behaviour of the first member of a homologous series. We know that of the fatty acids, formic acid exhibits properties which in many respects are different from those of the remaining members of the series and that therefore in many cases formic acid would not be a legal equivalent for acetic acid. On the other hand if a process is successful with propionic acid, we might reasonably expect it to be equally successful with butyric acid.

In the case of the Badische Anilin und Soda Fabrik v. Levinstein, although it had previously been proposed to couple diazonaphthalene hydrochloride with *phenol*, it was decided that invention was required to produce a dye-stuff by coupling diazonaphthalene hydrochloride with *naphthol* and sulphonating.

The diazo reaction had been discovered by Griess, "But," as Lord Justice Fry stated, "the value of any particular combination of these derivatives from the hydrocarbons was not within the range of the prophetic power of science." In the House of Lords, Lord Herschell stated "It is suggested that even though the particular substance was unknown, similar bodies arrived at by similar processes were well known, and that chemical analogy would at once indicate the supposed invention. A complete answer is given to this argument by Dr. Griess, one of the highest authorities on this branch of chemistry. He says, 'In 1864, I distinctly state that, by the combination of diazobenzol and phenol, dye was obtained, and if I had been a little cleverer, analogy would have induced me to prepare this very dye which is now under consideration. But analogy did not lead me to do that; analogy does not go a long way in chemistry.'"

This principle has recently been applied in the case of Osram Lamp Works Ltd., v. Z. Electric Lamp Manufacturing Co. It had previously been proposed to make filaments for electric lamps of the metal osmium. The patentees claimed the manufacture of filaments of the metal tungsten, which was cheaper and more effective. Except for the fact that the patentees selected one suitable process of decarbonising out of three known processes, their invention as stated in their specification, simply consisted in transferring to the metal tungsten, a process which had previously been proposed for the apparently analogous metal osmium.

Further examples might be given from the problems of stereoisomerism and the phenomena governed by the phase rule in which cases there are brilliant possibilities of prediction; however, I will simply give two final examples drawn from the Flour Oxidising Cases, the reports of which are a storehouse of felicitous illustrations in this field.

In one case it was held that invention was undoubtedly required to bleach flour by nitrogen peroxide when a previous unsuccessful process had employed ozone. It was justly said that if the innocuous ozone produced a taint in the flour, no one could have predicted that the strong smelling gas nitrogen peroxide would have successfully solved the problem. Lord Justice Farwell remarked that the inventor of the ozone process had left his wrecked barque as a warning to subsequent navigators of that channel. His process had failed and it could not have been foretold that the nitrogen peroxide process would succeed.

Against that it is instructive to consider a subsequent process which bleached flour by the action of the gases produced by subjecting air to the passage of a flaming arc. This patent was declared void as requiring no invention. It was known that the passage of a flaming arc in air produced nitrogen peroxide; Andrews had shown that nitrogen peroxide would successfully bleach flour; therefore although there was no evidence that anyone had actually used or proposed to use the gases from a flaming arc for the purpose of bleaching flour, yet nevertheless this application was obvious and practically speaking it could have been predicted. A few lines of the judgment in this case are worth quoting, since they show the prediction of which I have spoken above does not refer to absolute or mathematical certainty, but to reasonable certainty—the kind of certainty upon which we act in everyday life. Lord Parker said:—

"Under these circumstances, I think that any ordinary man with a working knowledge of chemistry would have inferred that the medium disclosed in Andrews' specification could be produced electrically. If he were a cautious man he might probably have thought it well to test by experiment the truth of his inference, not because he would doubt its truth but because the gaseous medium produced by the electric discharge might possibly contain some unexpected constituent which might spoil so sensitive a substance as flour. There would be no reason to think that there could be any such unexpected constituent, but a chemist, aware as he would be of the extent of the unknown compared with the known in chemistry, would naturally desire to make himself secure."

I am not suggesting that the possibility of prediction or otherwise is a unique factor in determining the presence of invention. Indeed invention is a function of a number of variables of which only one has here been considered. Prediction is certainly an important one; its bearing upon invention may be compared to that of Berthelot's principle of maximum heat development upon the occurrence of chemical reactions. We know now that in most cases, as an approximation, reactions take place in the direction indicated by thermo-chemical data, but we also know that these are only particular cases of a more fundamental law, that of the free energy gradient.

It would be easy to give examples demonstrating this statement. One important case is that of combination processes and especially cyclic processes; for instance a German patent was granted for a process of splitting up ammonium chloride by treating it with syrupy phosphoric acid, heating to expel the hydrochloric acid, and heating still further to expel the ammonia which was collected separately, thus leaving behind the syrupy phosphoric acid ready for a fresh cycle. Although this process does not work well on a large scale, no one can deny its ingenuity, yet it seems probable that it could have been predicted from scientific data a priori. Its merit appears essentially synthetic.

It is also necessary to add that in speaking of prediction the term is meaningless unless we consider the subjective lement, namely the person by whom the prediction could or could not be made. For the purposes of Patent Law his person is always the average operator who is skilled n the particular industry in question; in chemical industries this pre-supposes some knowledge of chemistry but not the very highest chemical attainments.

In order to allow for this subjective element the decision s to invention must always in the end rest to a certain xtent upon the experience, instinct and judgment of the erson who is making the decision. It is impossible to ormulate the decision in terms of hard and fast principles ust as it is impossible for us to give a set of differential quations to express a symphony or to decompose a unset into permutations of radiation frequencies. In all these cases there is a personal element involved and this must never be forgotten in considering the questions of Patent Law.

In practice the system does not work out so badly. I have prepared a table of the cases in which the validity of a patent was brought into question in English Courts during the five years 1908-1912. The results show that out of 74 cases, the patent was declared to be valid in 53 per cent. of the actions. Taking the chemical patents alone they were considered to be valid in 65 per cent. of the actions.

In about three-quarters of these cases the patentees were able to prove that infringement of their patent had actually occurred in spite of ingenious attempts to argue that the defendants were really doing something quite different. The actual figures are that the patent was proved valid and it was also proved to have been infringed by the defendants in 39 per cent. of all the cases and in 47 per cent. of the chemical cases.

This shows, therefore, that in about half the chemical cases the patentees were entirely successful in proving invasion of their rights.

Discussion.

Mr. W. P. Thompson agreed with Mr. Potts that for a patent generally to be valid, the result achieved must be something more than would naturally be predicted from the elements of the invention by a man in the trade without inventive faculty, but the amount of advantage over that which would naturally be predicted may be very small. They had had two cases in this district, first, that of Cannington v. Nuttall over a glass furnace. Every one of the parts of that furnace had been used before for the same purpose in the same way in glass furnaces, but the result of the combination produced so much better effect than was anticipated that the House of Lords decided the patent to be valid. Again in the case of Patent Exploitation Ltd. v. Siemens (the Burnley battery) it was decided in the lower court that every part of the invention was old, and the combination therefore no subject for a patent. In the Court of Appeal and the House of Lords it was unanimously accepted as a good patent, though it was admitted that every single part of the battery had been patented before for the same purpose. Lord Davy, who gave the decision in the House of Lords, stated that as the combination drove every other dry battery out of the market as soon as it came out, they were obliged to consider that there was some patentable novelty in the combination. Again, especially in mechanical patents, the very prediction is often the novelty. Take for instance the patent for making wood screws with a point. Hitherto screws had been made with blunt ends. By pointing the screw the screw-driver itself could work the screw into soft wood at any rate. Anyone could have invented this, but did not, but making the prediction and carrying it out was itself the invention, and the patent was sustained. If an invention were proved to be a distinct advance it made little matter whether it was a sudden departure or a gradual development.

PROF. W. R. HODGKINSON IN THE CHAIR.

BY-PRODUCTS FROM PEAT.

BY DR. F. MOLLWO PERKIN.

With the attention of everyone turned to-day to the production of new fuels and the recovery of by-products from coal and other sources for the use of internal combustion engines or oil-fed boilers, peat as a raw product is naturally being considered.

In Great Britain there are upwards of 6,000,000 acres of peat bog with an average depth of 12 feet. In Ireland there are about 3,000,000 acres of peat bog, some of the bogs being very deep. Peat as dug contains very large quantities of water, generally speaking from 80 to 90 per cent. In this condition, of course, it is of very little use, therefore it has to be, at any rate, partially dried. For the recovery of by-products it is usual to dry it down as far as 20 per cent. of moisture—that is if peat coke is to be one of the by-products. Probably each acre would yield from 3,000 to 3,500 tons of such dried peat. Taking the lower figure we arrive at the huge total of 1,800,000,000 tons of peat available in the United Kingdom, and in Ireland, where the average depth is greater, probably nearly as much again.

The great problem in dealing with peat, and the rock on which most of the older enterprises have split, is the removal of the moisture. If wet peat is subjected to hydraulic pressure it is only possible to remove a comparatively small proportion of the water, owing to it being bound up in the cellular structure of the peat. A similar difficulty applies to drying by heat.

Various methods have been used for breaking down the cellular structure of peat and thus obtaining it in a condition in which the moisture can be expelled, either by pressure or by air drying. Obviously, seeing what an enormous percentage of water is contained in peat, drying by artificial heat alone is out of the question. Generally speaking air drying has been found the most satisfactory, but it is a slow process, and is dependent, to a large extent, on atmospheric conditions. The methods most commonly employed on a large scale are :—

1. The peat is cut out of the bog by hand or machinery and then air-dried by stacking without undergoing any mechanical treatment.
2. The peat, after being cut out from the bog, is subjected to a macerating process in specially constructed machines.

The methods may be classed under two headings :—

(a) Macerating and adding extra water so as to form a peat slime which can be run into moulds.
(b) Macerating without the addition of water, then moulding.

By any or all of these processes, however, the difficulty of drying still remains. After maceration the water evaporates very much more freely, but it takes a considerable time for the briquetted peat to lose its moisture down to 20 per cent. Another difficulty is that when the briquettes are dried too rapidly they warp and crack.

In Ireland, Scotland, and other places peat is employed as a fuel. In such cases, however, it is simply cut into brick-shaped pieces and stacked in such a manner that a large surface is exposed to the air, and it is generally left several months before it is employed as a fuel. Peat prepared in this manner is not suitable for the production of hard coke and by-products, since it is of a more or less porous and spongy nature and occupies too much space.

Peat for the recovery of by-products, therefore, must be treated in such a manner that the cellular structure is broken so that when pressed or moulded it will form a hard briquette.

As already mentioned this may be done by means of macerating machinery. A very large number of these have been patented and several of them give very satisfactory results.

Thoroughly pulped peat, when moulded, forms a compact mass with practically no hollow spaces. Such peat, on exposure to the air, dries comparatively rapidly, the drying taking place throughout the mass. After the outside layer has dried it may be exposed to damp weather without further moisture being taken up, because the outside dried part swells up, the pores close, and moisture is prevented from entering the interior. In dry weather the pores open out again and the drying continues.

The machines for pulping or macerating the peat consist generally of a vertical cylinder or horizontal half cylinder in which knives placed in the form of a screw thread rotate. The raw peat is fed in at one end, and by means of the rotating knives is thoroughly mixed and pulped and carried forward to the other end of the cylinder, where it is extruded in the form of a porridge-like mass. Sometimes it passes directly forward by means of a band into a briquetting machine. The briquettes are then placed on wooden frames which are piled one above the other in open sheds where they are air-dried.

It is not intended here to go into the merits of the different machines which have been patented and employed for macerating the peat. The cellular structure can, however, be broken down and the water then pressed out hydraulically by other means than maceration.

Even if peat is only intended for fuel, machine-made briquettes, that is briquettes made from macerated peat, are far more efficient than when the peat is simply cut and dried. The calorific value is higher and the briquettes burn away more slowly. In Holland and in Norway and Sweden machine made briquettes are largely used for domestic heating purposes.

Other methods have been tried for breaking the cellular structure and thus obtaining the peat in a condition in which it will dry more readily. Electricity has been used to break down the cells. A plant of considerable size was put down at Kilberry, in Ireland, but unfortunately was not successful. The peat was scooped out of the bog and placed in a rotary hydro-eliminator which removed the surface water. It was then passed through a press and subjected to an alternating electric current. This, it was claimed, broke up the cells and allowed the water to run out. A number of other electrical processes have been suggested.

A recent patent in which it is claimed to render the natural water expressible, is to pass an electric current through peat heated to a temperature of at least 100° C., under a pressure sufficient to prevent the formation of steam. The current may be either direct or alternating, although the direct current is preferred. A pressure of 200 volts is stated to be the most economical. Personally I do not think that the difficult problem of eliminating water will be solved by the use of electrical processes.

Other methods are the addition of bleaching powder or lime to the peat, thoroughly mixing and heating to a temperature of 30° to 40° C. The objection of these processes is the large amount of handling they entail, and, it must be remembered, for a peat proposition to be a paying concern very large quantities must be worked up. The addition of lime or bleaching powder will also increase the ash content.

Ekenberg found, by heating peat to 150° or thereabout, under pressure, that the cells were broken and that the water could be readily removed.[*]

In a recent French patent it is claimed that if raw peat is simply heated to 60°—100° and allowed to cool the moisture can be removed by pressure. In other processes the peat is heated by live steam under a pressure of several atmospheres. The pressure is then suddenly released and the peat dropped into the receptacle of a specially constructed hydraulic press. On the application of pressure the water contents are reduced to about 28 to 30 per cent. in the course of a few minutes. This particular process only occupies about 30 minutes, that is to say, peat, direct from the bog containing 80 to 90 per cent. of moisture, can be reduced down to 30 per cent. in this time. In all these methods, however, the great bulk of the wet peat to be dealt with has to be taken into consideration.

Bacterial processes have also been suggested. In one it is claimed that the bacteria produce hydrogen peroxide which oxidises the peat and converts it into a condition in which the water is readily eliminated.

Carbonisation of peat.

The oldest method of coking peat, and which is still to certain extent employed, is to coke it in heaps in th same manner as the old charcoal burning process, all th by-products being thus lost. The only satisfactor method, and the only one likely to be a commercial success is to coke in some form of oven and recover the by-pro ducts. If, however, a firm dense coke which will be value in the metallurgical industry is to be obtained, it necessary to produce briquettes formed from well macerate and dried peat before coking. If there is much moisture then the coke formed will be too porous and friable. An alternative method is to coke moderately dried peat, which need not be briquetted, and to briquette the resulting coke in a manner somewhat similar to that employed in the patent fuel industry.

---

[*] See this Journal, 1903, 1122, 1238.

When peat is coked various by-products are obtained, the quantities and proportions of which depend upon the quality of the peat and the method of coking employed. A peat containing much mineral matter will give a coke which will not be of much value for metallurgical purposes, but this will not to any extent affect the by-products. Peat which contains a high percentage of nitrogen will give a high yield of ammonia, but it will be necessary to carbonise at a moderately high temperature in order to obtain the maximum yield of ammonia. On the other hand the character of the oils will be altered. Generally speaking low temperature carbonisation seems to yield the most valuable oils, but there is no reason why the oils should not be driven off at a low temperature, and then, either by moving the partly carbonised peat to a hotter zone in the retort or by increasing the temperature of the whole retort, the maximum yield of ammonia should not also be obtained. The first would be a continuous process and the second an intermittent one.

On carbonisation of peat the following products are obtained :—Gas, oils containing paraffin wax, phenols, ammonia and small quantities of other bases, methyl alcohol and acetone, acetic acid, pitch, and coke.

From the distillation of 576 tons of air-dried briquetted peat containing 31 per cent. of moisture at Oldenberg in Germany the following products were obtained per one ton of peat. In order to make a comparision I give the results obtained in my laboratory from a Scotch briquetted peat containing about 16 per cent. of moisture.

	Oldenberg.	Perkin.
Oils	54·0 lb.	50·0 lb.
Paraffin wax	6·0 ,,	not determined.
Phenols	26·0 ,,	28·0 lb.
Methyl alcohol	6·8 ,,	5·1 ,,
Ammonium sulphate	6·2 ,,	30·2 ,,
Calcium acetate	10·0 ,,	8·0 ,,
Pitch	4·0 ,,	3·5 ,,

The Oldenberg peat contained 0·7 per cent. of nitrogen, and the Scotch peat 2·1 per cent. which accounts for the difference in the yield of sulphate of ammonia. Other differences are readily accounted for when it is borne in mind that my results were obtained from the distillation of 5 kilograms of peat at a time, whereas the German results were from 576 tons in quantities of several tons at a time.

The gas, having a good calorific value, can be burned under the retorts, and should be sufficient to supply all the heat required when once the process has started. This is shown by the analyses of gases produced :—

	Oldenberg.	Perkin.
Carbon monoxide	8·6	11·4
Methane	14·8	11·5
Unsaturated hydrocarbons	1·0	3·4
Hydrogen	23·6	19·0
Carbon dioxide	27·4	31·4
Nitrogen	22·5	19·9
Oxygen	2·2	0·4

The yield of gas is between 5000 and 6000 cubic feet per ton of peat carbonised.

The calorific value of the Scotch peat briquettes containing 16 per cent. of moisture was 8558 B.T.U., that of the coke produced 13,680 B.T.U.

The tar from which the oils are obtained by distillation, is generally considerably contaminated with finely divided carbon which, on distillation, causes further carbonisation. A rather brittle pitch is thus obtained if the whole of the oils are distilled off. If, however, live steam is injected towards the end of the distillation a much better pitch is obtained, which can be used for insulating purposes.

The oils obtained in my laboratory consist mainly of saturated hydrocarbons. They have a peculiar burnt peaty odour. This smell, however, can be removed by treatment with about 1 per cent. of strong sulphuric acid. The lighter oils could be used for internal combustion engines. The heavier oils lack viscosity, so are not of much use for lubricating purposes, but they could be used as oil fuel or might be cracked into light spirit and then employed for automobiles. The phenols, which are obtained in rather large quantities, contain, amongst other products, guaiacol. They have already been employed for making disinfectant bodies and appear to form very good antiseptics.

The Peat, Coke and Oil Syndicate, of Doncaster, carbonise peat containing from 50 to 60 per cent. of moisture. The peat is not briquetted previous to being carbonised, the briquetting operation being carried out with the peat coke obtained in the process. This is mixed with certain binding materials, some of which are obtained from the peat by-products. The briquettes are then pressed and coked again in the usual manner. From four lots of one ton each carbonised, the following by-products were obtained :—

Water-free crude oils	8·8	gallons
Ammonium sulphate	21·2	lb.
Spirit (petrol)	3·9	gallons
Spirit 160°—200°	3·5	,,

Apparently the methyl alcohol and phenols had not been worked up. The paraffin was left in the pitch, which makes a good insulating material. The briquettes produced by this process are very hard and have been well reported upon for steel smelting, the average crushing pressure being 812 lb. per square inch. It is now proposed to erect a plant capable of dealing with 100 tons of coke per week. Preliminary tests have shown that the by-products alone more than cover the whole costs of the process and that the sale of the coke is all profit.

Peat for power purposes.

Another method of working up peat and producing by-products is to employ it for the manufacture of power gas. In this respect some very interesting experiments have been made in Canada by the Department of Mines.

In a modified Körting peat gas producer the best results seem to have been obtained when the peat contained from 25 to 30 per cent. of moisture. With larger quantities of moisture there is great difficulty in eliminating the tar from the gas. It is stated, however, that peat gas power plant has a distinct advantage over one using bituminous coal. With coal the accumulation of tar in the valves and cylinder is difficult to remove, and necessitates the shutting down of the engine. Whereas tar from peat is readily removed by injecting into the open end of the cylinder a mixture of oil, soap and water. This completely dissolves the tar which is thrown out by the forward movement of the cylinder.

The Power Gas Corporation have also a special producer in which peat is employed. In this producer peat containing 50 per cent. of moisture can be satisfactorily employed. The Company have a special mechanical process for drying peat from 80 per cent. to 50 per cent. of moisture which renders them independent of weather conditions. It is claimed that by this process the total cost of the peat is only 3s. per ton including excavating, manufacturing, and drying. In all producer processes the peat is completely burnt up, and there is thus no carbon as a by-product. Larger quantities of ammonium sulphate are, however, obtained than by distillation in retorts. On the other hand the tar obtained is less valuable. Given a peat containing a fair proportion of nitrogen, it is claimed that the yield of ammonium sulphate is more than sufficient to pay all working and depreciation costs, so that the power gas is obtained free of cost.

MR. G. W. THOMPSON IN THE CHAIR.

RECENT IMPROVEMENTS IN GAS MANUFACTURE.

BY ALFRED E. FORSTALL.

In the following paper I have limited myself to the manufacture of illuminating gas in central station plants. The process divides itself into two stages, the generation of crude gas from the raw materials, and the purification of this crude gas in order to make it fit for general use.

Taking first the generation of coal gas, an important recent improvement has been the development and quite general installation of retorts set vertically, which were tried unsuccessfully in the early years of the nineteenth century. Retorts set horizontally were, however, finally adopted and used solely, until, in 1885, M. André Coze developed a setting in which the retorts were inclined at an angle of from 29° to 33° to the horizontal. At such angles the coal would spread fairly evenly over the whole length of the retort by gravitation and the coke would run out fairly easily when the charges were thoroughly carbonized. Though adopted quite generally on the Continent of Europe and in Great Britain, only three important installations of inclined retorts, and not more than five or six minor ones, were made in the United States.

In the year 1902 two different types of vertical retort settings, the intermittent and the continuous, were brought to the notice of gas men. The intermittent type, in wheh an amount of coal which nearly or entirely fills the retort is dropped in at one time and allowed to remain until completely carbonized, when the resulting coke is dropped out, also at one operation, was developed by Dr. J. Bueb, of the Deutsche Continental Gas-Ges., in the gas works at Dessau, Germany. The first patent taken out for these retorts, in the early part of 1902, described them as provided with outlets, spaced from top to bottom along the whole length of the retort and opening into a verticle flue so placed in the setting as not to be exposed to a high heat, the object being to permit the gas as it was drievn out of the coal to escape to the hydraulic main without being subjected to contact with either the highly heated coke or the walls of the retort. Settings built under this patent were put into operation in 1903, but the side outlets were abandoned soon after actual work began, and by 1905 the design had been developed to that which is now being employed, in which the gas evolved from each portion of the charge travels through all the superincumbent portions before it escapes to the hydraulic main.

As the Dessau verticals have been developed in Europe, the retorts are made either four metres or five metres (13 ft. 2 in. or 16 ft. 5 in.) long with cross-sectional dimensions of approximately 9 in. by 22in. at the top and 14 in. by 27 in. at the bottom, and are set in groups of either twelve or eighteen, each group being heated by its own gas producer, or generator furnace, and provided with its own recuperators. In the only installation of this type in the United States, which is at Providence, R.I., the retorts are 13 ft. 2 in. long with the same cross-section as given above, and are set ten in a bench. The coal is charged into the retorts from over-head bunkers and the coke is dropped into buggies or into a conveyor.

The combustion of the producer gas takes place in a combustion chamber surrounding the lower ends of the retorts, and the hot products of combustion pass horizontally to the back of the setting and then up to a second set of horizontal flues running to the front, up again to a third set of horizontal flues running to the back, and then into a fourth set of flues running to the front, and pass out from the top of the bench to the recuperators and thence to the chimney.

In the United States the United Gas Improvement Company began experimenting with intermittently filled vertical retorts about 1908. As a result of these experiments the benches of this type last built contain nine retorts each 18 ft. 6 in. long with an oval section 12 in. by 22 in. at the top and 18 in. by 30 in. at the bottom. The reasons given for the use of the larger cross section are that when the coal was smaller it coked too rapidly at the top of the retort causing excessive pressure at the bottom, that with the small retort the discharge of the coke did not take place satisfactorily except when the whole charge of coal was thoroughly carbonised, while a large retort will discharge readily even when the coal has not been thoroughly carbonized, and that the larger retorts produce larger coke, an advantage in many localities.

In this type of setting the combustion of the producer gas also takes place around the lower ends of the retorts and the products of combustion pass upwards to the top of the setting.

The German practice is to fill the retorts completely with coal, while the United Gas Improvement Company leave 4 ft. of the retort at the top empty, to provide a space in which the heavy hydrocarbon vapours may be converted into gas by the action of radiant heat.

It is interesting to note that Mr. C. F. Dietrich obtained in 1880 a United States patent making claims for a setting of retorts which were very similar to those of the original Bueb patent, including even the lateral openings into a channel protected from heat through which the gas could pass out from the retort. At that time, however, conditions in this country were favourable to the manufacture of carburetted water gas and the field for coal gas did not seem to warrant the trouble of developing a new method of manufacture, so apart from building one experimental bench nothing was done by Mr. Dietrich to develop these retorts.

The reason for the provision of side outlets in the retorts under the original Bueb patent was the belief that, if compelled to pass up through the incandescent charge, the hydrocarbons first evolved from the coal would be over-decomposed into hydrocarbons of lesser value from the illuminating and calorific value standpoint, and that carbon and naphthalene would be formed and cause trouble during the handling of the gas as it passed from the generating apparatus to the consumer. The disadvantage of the side outlets was that the retort could not be heated around its entire perimeter and that therefore more fuel was required for the carbonization of a given weight of coal than where the heat could be applied around the entire perimeter. When the lateral outlets were bricked up and the gas taken off from the top of the retort, the decomposition of the hydrocarbons was not as great as had been anticipated provided the retorts were heated to a very high temperature and care taken to fill them completely with coal. It was claimed that under these conditions the generation of gas from the portions of the coal in contact with the internal surfaces of the retorts was rapid, owing to the high heat, and this coal was at once converted into a compact coke, impermeable to the gas generated. The gas was therefore forced to pass, from all points of the layer in which carbonization was taking place, inwards and upwards through the uncoked and more permeable portions of the charge. Its temperature was thus prevented from rising beyond the point at which over-decomposition of the heavy hydrocarbons, with the formation of carbon and naphthalene, would take place.

This theory as to the course followed by the gas in passing through the charge in an intermittently charged vertical retort was for a long time accepted as correct, but recently Dr. H. G. Colman in England and Mr. O. B. Evans in the United States have reached the conclusion, as the result of experiments, that in reality only part of the gas travels through the core of uncarbonized coal and the rest passes through the incandescent coke.

Dr. Colman argues that if even the largest portion of it travelled through the uncarbonized coal the gas would show some of the characteristics of a gas produced at a low temperature, modified to a certain extent by the gas produced in the latter stages as the temperature of the coke is raised, and that the tar produced would be a low temperature tar containing but a small amount of aromatic substances. As a matter of fact his analyses had shown that the gas possessed all the characteristics arising from exposure to high temperatures, the proportion of hydrogen to methane being even higher than that obtained from the same coal when distilled in highly heated, horizontal retorts, and that the tar produced, although containing more paraffin derivatives than did tar from horizontal retorts, consisted chiefly of aromatic substances, showing that, during its formation, the vapours produced at low temperatures must have been subjected to a considerably higher temperature before passing out from the retort. This could not happen if even the larger part of these vapours passed through the uncarbonized coal, since then the travel would be in a direction which would expose them to a constantly decreasing, instead of to a higher, temperature. Moreover the existence of a high pressure in the retort at the commencement of carbonization when the area of the core was the greatest, and the diminishing of this pressure as carbonization proceeded, although the rate at which gas was produced did not decrease greatly during the first seven hours of the charge, while the area of the core did decrease quite rapidly, was strong evidence that the gas did not find its principal direction of travel through the core. He concludes that the great bulk of the gas is produced on the outer side of the pasty layer formed by the coal as it carbonizes and that this gas mainly travels through the hot coke, mixing with the poorer gas produced by the continued action of heat on the low temperature coke first produced. The gas produced on the inner side of the pasty layer will pass through the coal, and he considers it probable that the vapours which pass in this direction form the undesirable paraffin constituents of the tar, so that as far as travel through the core does take place it is disadvantageous.

Mr. Evans, reasoning from the pressure conditions existing in the interior of an intermittently charged vertical retort, came to the conclusion that during the early part of the charge, when the layer of coke formed around the perimeter of the retort was compact and offered no ready means of passage to the gas, most of the gas produced was obliged to force its way through the pasty layer of coal, in the initial stage of carbonization, and pass up through the uncarbonized coal, but that as the outer layer of coke contracted and cracked under further heating most of the gas formed in the latter portions of the charge passed up through this coke. He reached the conclusions that of the gas made during the first six hours of the charge, which amounted to 70 per cent. of the total amount of gas made, 45 per cent. passed up inside of the pasty layer through the core and 55 per cent. through the hot coke next to the retort walls, and that the gas evolved at low temperatures escapes through the core while that evolved at high temperatures escapes along the wall. Mr. Evans considers that this is advantageous since the low temperature gas is more subject to injury by over exposure to heat, and this is correct provided that after leaving the coal this gas is exposed to heat in a free space at the top of the retort.

This discussion as to the path followed by the gas in passing out from intermittently charged vertical retorts has been given somewhat at length, because of the claims originally made that the freedom from naphthalene experienced with gas made in such retorts was largely due to the fact that the travel was through the cool core of uncarbonized coal.

While the work of the Germans in connection with vertical retorts was confined entirely to those charged intermittently, in England the design of such settings was approached with the idea of adapting them to continuous carbonization. This had been experimented with in connection with the horizontal retorts and had given good results as far as the quantity and quality of the gas were concerned, but had always proved a failure from the manufacturing standpoint because of mechanical troubles.

In 1902 there was built in Exeter a setting of vertical retorts into which the coal was charged at regular intervals, the length of which could be varied, in amounts varying from 2 lb. to 7 lb. The retorts, about 9 ft. long, were made straight for part of the distance and then were curved so that the coke was withdrawn through an opening in the side of the setting at right angles to that in the top through which the coal was charged. The coke was drawn intermittently in comparatively large amounts at one time so that the extent to which the retort was filled with coke and coal undergoing carbonization varied quite considerably. After being tried in several places in England further use of the settings was abandoned because of trouble experienced with the working of the coal feeding device and in keeping the curved portion of the retort from cracking, and also with the formation of lampblack owing to the large variation in the volume of the charge, because of the intermittent drawing of the coke, and the consequent variation in the extent to which the gas passing off from the charge was exposed to heat in the vacant space left at the top of the retort.

While this retort was being experimented with, Messrs. Woodall and Duckham were developing at Bournemouth, England, another type of continuously charged and operated vertical retorts. Starting with a mechanical coal feed as well as mechanical and continuous extraction of the coke, the former was soon abandoned because of operating difficulties, and the introduction of coal into the retort is now brought about entirely as a result of the extraction of coke at the bottom. The construction of the coke extractors has also been very materially changed from the form shown in the original patent and the first plant erected.

As now built each retort is surmounted by a charging magazine filled through a rotary valve from an overhead coal bunker and holding enough coal for two hours' supply. There is free communication between the magazine and the top of the retort, the coal in the former being supported by that in the retort. As the coke extractor withdraws the coke from the bottom the whole column of material in the retort settles and coal runs in at the top from the magazine, the supply of coal in which is replenished at intervals of from twenty minutes to an hour.

The coke extracting device consists of a rotating horizontal shaft provided with arms placed spirally around it and of loose arms hung on hinges at their upper end and having sufficient weight to hold back the coke except as their lower ends are pushed out by the action of the revolving shaft. The coke is discharged into a closed hopper which will hold the amount produced during two hours and is intermittently emptied either into dumping wagons running on an industrial railway track, or into a conveyor. The extractor can be run at varying rates of speed to suit the differing amounts of coal that can be carbonized under varying conditions.

As originally built the settings consisted of four oval retorts 25 ft. long and having cross-sectional dimensions of practically 9 in. by 23 in. at the top and 20 in. by 29 in. at the bottom. In recent installations the retorts have been replaced by rectangular ovens, or slots, of the same length and having cross-sectional dimensions of 8 in. by 3 ft. 10 in. at the top and 20 in. by 5 ft. 3 in. at the bottom. At the top of these slots there is a division plate, extending down an adjustable distance, which forms two separate spaces, into one of which the coal magazine opens while the other is kept free from coal so that the gas can pass out through it and in passing out be exposed to radiant heat for the purpose of decomposing the hydrocarbon vapours with low boiling points. As the settings are operated it would seem that the desired effect was obtained to only a very limited extent, if at all.

The combustion of the producer gas begins at the top of the setting and the products of combustion pass down, surrounding the retorts and are taken off into the recuperators a short distance above the bottom. From the recuperators they either pass directly to the chimney or in some cases are taken through the tubes of a waste heat boiler which furnishes practically all the steam required for the operation of the plant.

The primary air is heated before entering the furnace by passing across the setting in contact with the side walls of the retorts at their lower end, and the coke is sufficiently cooled in this way to require no quenching.

While Messrs. Woodall and Duckham were developing their design Messrs. Young and Glover were also doing, at St. Helens, England, work which has resulted in what is now known as the Glover-West system of continuous vertical retorts. The chief differences between the Woodall-Duckham and the Glover-West systems are in the form of the coke extractor and in the methods of heating the retorts. In the Glover-West, as in the Woodall-Duckham, coal runs into the retorts from a charging magazine in free communication with the top, as the coke is extracted at the bottom. The coke extractor is in the form of a worm set with its axis vertical and slowly revolved, and delivers coke into a receiving chamber, large enough to hold that produced during a period of two hours and regularly discharged at intervals of any length less than two hours. The retorts are oval in section and have a total length of 20 ft. with cross-sectional dimensions of 10 in. by 30 in. at the top and 22 in. by 36 in. at the bottom. To the bottom of each one is added a cast iron chamber 3 ft. deep, at the bottom of which is placed the coke extractor. The retorts are set in groups of eight and the setting is divided into either two or four chambers so that the retorts can be worked in units of four or two. The combustion of the producer gas takes place at six points evenly spaced along the portion of each chamber extending from the bottom to within about 5 ft. of the top, and the products of combustion, after passing horizontally around each set of retorts, ascend through vertical flues to chambers surrounding the upper 5 ft. of the retorts, from which they pass to the chimney. The secondary air is heated by passing the cast iron chambers at the lower end of the retorts and this cools the hot coke on its way to the coke extractors, and does away with the necessity of quenching it when taken from the coke chambers.

Shortly after, and partly as a consequence of, the successful introduction of intermittently charged vertical retorts the method of operating horizontal retorts was substantially modified. This had been to charge such retorts with a layer of coal about 4 in. to 5 in. thick leaving a large free space above the coal, through which the gas passed to the mouthpiece and standpipe. The maximum charge for each of the 9 ft. retorts with one end permanently closed, in general use in the United States, was from 340 lb. to 350 lb. of coal. The front end of the retort being enclosed in the front wall of the bench for a depth of 13 in., almost a foot of the length was not effective for carbonizing purposes and the weight of charge was not more than 45 lb. and in many cases not over 40 lb. per lineal foot of the effective portion. There had been some theoretical discussion of the advisability of more completely filling the retorts, but this had not produced any result in practice until the completely filled vertical retorts afforded an object lesson of the freedom from carbon and naphthalene troubles secured by reducing the extent to which gas was exposed to contact with the highly heated walls of a retort. In England, where the use of through retorts, or those open at both ends, was common, it was easy to change from the lighter charges to the heavier ones, but in the United States it was necessary to change to the use of through retorts instead of single end ones before the increase in weight of charge could be made, since where the coke must be drawn from the retort by means of a rake it is necessary to leave sufficient space above the charge to permit the free passage of the rake, while with the through retorts, from which the coke can be pushed, provision for the passage of the rake does not have to be made. The present practice, where through retorts are in use, is to charge about 70 lb. of coal per lineal foot of the effective portion of the retort. When so charged from 66 per cent. to 70 per cent. of the area of the retort is occupied by coal, leaving only from 30 per cent. to 34 per cent. of the area for the passage of the gas, while when weighing 40 lb. to 45 lb. per lineal foot of retort the charge only occupies from 30 per cent. to 36 per cent. of the area. The expansion of the charge during the coking process makes the actual free space left in the retort still smaller in proportion for the heavy charges.

The use of heavier charges resulted in a large increase in the amount of gas made per pound of coal with a decrease in the operating difficulties caused by the presence of free carbon in the gas and in the tar. In England the yield of gas, which formerly averaged only about 10,500 cu. ft. per ton of 2,240 lb. of coal now averages nearly 12,000 cu. ft., while in one plant in the United States, that at Worcester, Mass., the former average yield of 5 cu. ft. per pound has been increased to 5·9 cu. ft. In other works in the United States which have adopted the heavy charges the yields of gas have been increased about 10 per cent. as compared with those formerly obtained. This increase in yield has not been accompanied by a decrease either in the illuminating value or in the calorific value per cubic foot and has therefore resulted in obtaining a greater total illuminating value and calorific value in the gas from a given quantity of coal.

The yield from the continuous vertical retorts is also greater than that formerly obtained from horizontal retorts operated with light charges, but in this country has not been as large as that obtained from the horizontal retorts at Worcester, Mass.

Some analyses have been obtained of the gas made in each of two plants, one having horizontal retorts and the other vertical retorts of the Woodall-Duckham type. The horizontal retorts are operated with moderately heavy charges which, however, do not come up to 70 lb. per lineal foot of retort. These plants are under the same management and the coal used is purchased from the same company and is presumably practically the same, so the analyses show to some extent the difference in the gas due to the difference in method of carbonization.

	Horizontal retorts.	Vertical retorts.
	per cent.	per cent.
Carbon dioxide	1·44	1·49

Illuminants	3·15	3·98
Oxygen	0·48	0·28
Carbon monoxide	4·75	6·90
Hydrogen	51·36	45·02
Methane	33·60	37·33
Nitrogen	4·55	4·44
	100·00	99·99
Candle-power (Sugg D burner)	13·60	15·57
Calorific value—		
(B.T.U. per cu. ft. by calculation)	610·00	—
(B.T.U. per cu. ft. observed)	—	615·00
Yield per pound of coal	4·85	5·39

The total illuminants run slightly higher, and there is much less hydrogen in proportion to the methane in the gas from the vertical retorts than in that from the horizontal retorts. The illuminating value of the gas from the vertical retorts is also higher while the yield per pound of coal was 10 per cent. higher. During the period over which the analyses of the gas from the horizontal retorts were taken very wet coal was being carbonized and this may have affected the illuminating value and the yield of gas, which were lower during this period than the average for the preceding month, but even the averages for that month were lower than the results obtained from the vertical retorts, which, however, were those made during a test lasting eight days, and in regular working results have not been quite as good.

Comparable analyses of the gas made in the working scale testing plant at the gas works in Birmingham, England, both in intermittent vertical retorts, of the Dessau type, but apparently charged so as to leave a free space above the coal at the top of the retort, and in horizontal retorts, have been given by Dr. W. B. Davidson (see table on p. 401).

Dr. Davidson observes that the gas made in the vertical retorts is deficient in unsaturated hydrocarbons and methane and high in hydrogen, and that a cursory examination of the analyses leads to the conclusion that the hydrocarbon gases are subject to more drastic degradation before leaving the retort in the vertical system than they are in the horizontal system, but that it is not unlikely that the gas suffers both in quality and volume by the escape uncracked of a larger proportion than usual of tar oil vapors.

NOTE.—The illuminating values given by Dr. Davidson cannot be compared directly with those given previously since they were obtained from the Metropolitan No. 2 Argand burner and are probably about three candles higher than would have been obtained had the Sugg D Argand been used, as was done in the other case.

Experience with the United Gas Improvement Company verticals operated with a large free space above the coal seems to show that the provision of this free space leads to an improvement in the illuminating and calorific value of the gas, which is obtained at the expense of the extra quantity of tar produced when the retorts are completely filled according to the strict use of the Dessau system.

As far as the quality and quantity of the gas are concerned, intermittent vertical retorts of the Dessau system give poorer results than are obtained in horizontal retorts, while the intermittent verticals of the United Gas Improvement Company type and the continuous verticals do not give any better results along these lines than can be obtained from properly operated horizontal retorts. The improvements effected by the use of vertical retorts consist in a saving of labour in medium size plants in which it is impossbile to work charging and discharging machinery for horizontal retorts to advantage, and in greater freedom from trouble caused by free carbon and naphthalene, while the sulphur compounds other than sulphuretted hydrogen are also produced in smaller amount. In addition there is a saving in the ground space required, although it is necessary to go higher into the air with verticals. To these advantages the continuous vertical retort system adds that of practically complete avoidance of the smoke and steam emitted during the charging and discharging of either horizontal retorts or intermittent vertical ones.

The work recently done in determining the character of the products given off by coal subjected to distillation at different temperatures indicates that the greatest efficiency, from the gas making standpoint, in the carbonization of coal could be obtained by so adjusting the heating of continuous vertical retorts that the temperature of the upper 2 ft. or 3 ft. of the charge should never exceed 1000° to 1100°F., while that of the lower portion of the charge would be carried as high as 1800°F. By this method of heating the rich hydrocarbons would be driven off from the coal without having to come into contact with very highly heated surfaces, while the gas remaining after these hydrocarbons were driven off, which is of such a character as not to suffer to any great extent from such contact, would be entirely expelled from the coal in the lower portion of the retort. In order to decompose the heavy hydrocarbon vapours, which would otherwise condense into tar, in such a manner as to convert them into the maximum amount of permanent gas mixed with hydrocarbon vapours that could be carried by the gas, with the setting free of the minimum amount of carbon, all the gas leaving the top of the charge should then be passed through a free space exposed to heat radiated from walls carried at a temperature adjusted to the rate of travel of the gas, but probably about 1400° to 1500°F. This free space could be maintained either in the upper part of the retort or, if this leads to difficulty in feeding the coal, it might be entirely separate from the retort and possibly common to several retorts.

This method of manufacture would increase the quantity and quality of the gas at the expense of the tar and would not be advantageous unless the value of the gas gained was greater than that of the tar lost. It has never been actually worked but in my opinion is entirely feasible.

The recent improvements in connection with the manufacture of carburetted water gas consist in the devising, and putting into general use, of appliances for measuring the amount of air blown through the fuel bed during the "blow," or heating up period, and the amount of steam passed through the fire during the "run," or gas making period, together with the use of electric pyrometers for indicating the temperatures existing at selected points in the checker brick of the carburetter and superheater of the type of apparatus most commonly employed in the manufacture of this gas. The use of these appliances makes it possible to determine, and operate the apparatus constantly under, the conditions of blast, amount of steam used and temperature to which the oil vapours are subjected which give the best results, and by so doing to decrease the amount of fuel used and increase the efficiency of the conversion of the oil into oil gas, as compared with the former more or less hit-or-miss operation.

Purification.

In the second division of the process of gas manufacture, that of the preparation of the crude gas for delivery to the consumer, the recent improvements have been chiefly in connection with the removal of hydrogen sulphide and the other sulphur compounds present in the crude gas. For many years attempts have been made to use for the removal of hydrogen sulphide from coal gas the ammonia obtained from the gas itself. About 1886 a process for doing this was devised by Claus in Belfast, Ireland. Although chemically correct it proved too complicated mechanically and was finally abandoned largely because it was impossible to keep in working order the numerous pumps required for its operation. It is possible that if modern centrifugal pumps had been available the process might have been successfully operated.

In the United States an extremely simple method of purification of gas from sulphuretted hydrogen by means of ammonia has been recently devised by Mr. Jas. G. O'Neill and used on gas produced in coke ovens and sold for for illuminating purposes.

The ammonia in ordinary ammoniacal liquor is already largely saturated with sulphur and carbon dioxide, and one of the chief problems in connection with the use of this liquor for more complete removal of sulphuretted hydrogen is to accomplish its conversion into a condition suitable for combination with sulphuretted hydrogen without introducing too much complication of apparatus. Mr. O'Neill has solved this problem in a very simple manner by using liquor withdrawn from the still of the Coffey type, which is in general use in gas works for the concentration of ammoniacal liquor. He finds that when the liquor fed to the still has reached the point at which it has a temperature of 214° to 215°F., it has lost 80 per cent. to 90 per cent. of the hydrogen sulphide and 70 per cent. to 80 per cent. of the carbon dioxide, but still retains practically all the ammonia, which it contained when it entered the still. When brought in contact with crude coal gas in scrubbers of the ordinary type this liquor can take up on an average 500 grains of hydrogen sulphide per gallon and if used in sufficient quantities will reduce the hydrogen sulphide from as much as 900 grains, down to from 20 to 30 grains, per 100 cu. ft. of gas. If the complete removal of the hydrogen sulphide with liquor is attempted the average efficiency of the liquor is much less than this, and it is more economical to use the liquor only to the extent named and then finish the removal of the sulphuretted hydrogen by the ordinary process of purification by means of hydrated sesquioxide of iron.

The process devised and used by Mr. O'Neill adds to the apparatus customarily found in gas works only a heat exchanger, in which heat is transferred from the hot liquor coming from the concentrating still to the cool liquor on its way to the still, and a cooler for further cooling the treated liquor, both of which are simple and inexpensive.

Apparently this process could be adopted in many coal gas works with a saving in the labour required to operate the oxide of iron purifiers and also in the investment in the purifiers required for a given quantity of gas.

In Europe, where the gas coals contain as a rule more sulphur than do those in common use in the United States, and on the Pacific Coast, where gas is largely made from crude petroleum containing a somewhat high percentage of sulphur, the problem of reducing the amount of sulphur compounds, other than hydrogen sulphide, contained in crude illuminating gas has had some importance. In those parts of the world, therefore, attention has recently been paid to new methods of removing the principal one of these sulphur compounds, carbon bisulphide.

Of the more recent processes having this object the one first brought to the attention of gas engineers was that devised by Messrs. Hall and Papst and used since 1908 for the treatment of all the gas made, about 3,000,000 cu. ft. per day, in the works at Portland, Oregon. In this process the gas is merely heated to a temperature of from 1300° to 1600° F. by being passed through tall cylindrical vessels, formed of steel plates lined with fireclay blocks and filled with a checker work of firebrick, which are heated by the combustion in them of fuel oil. The vessels are in pairs, one being in process of heating while gas is being passed through the other. The operations are reversed as soon as the vessel through which the gas is passing becomes cooled below the effective temperature. Under the effect of heat, the carbon bisulphide reacts with the water vapour present in the gas and is largely converted into hydrogen sulphide, which is removed by passing the gas through an additional set of purifiers containing oxide of iron.

Another process which has been employed on a large working scale is that devised by Mr. E. V. Evans and used since the beginning of 1913 to treat all the gas made, about 10,000,000 cu. ft. per day, at a works of the South Metropolitan Gas Company, of London. This process utilises the catalytic effect of nickel in accelerating the reaction between carbon bisulphide and steam, by which hydrogen sulphide is produced and carbon set free. The catalyst is in the form of balls, presumably of fireclay, 1 in. in diameter impregnated with nickel obtained by the reduction of the chloride in a current of hydrogen. These balls are contained in tubes having a length of 11·5 ft. and a diameter of 6 in., through which the gas to be treated is passed. Before reaching the catalysing tubes the gas passes through heat exchangers, or recuperators, in which it absorbs heat from the gas passing out from the apparatus, and then through preheating tubes in which its temperature is raised to 750° F. With this preheating of the gas it is possible to carry on the process while maintaining a temperature of 800°F. in the catalysing tubes, and the principal direction in which the process has been gradually improved has been this preheating of the gas before it enters the catalysers. A single combustion chamber, supplied with producer gas from an outside producer, furnishes the heat required by both the preheating and the catalysing tubes. After about thirty days' use it is necessary to stop the flow of gas through a set of catalysers and blow air through them in order to burn off the deposited carbon which is found to be, at times, 50 per cent. in excess of the quantity calculated from the amount of carbon bisulphide reduced to hydrogen sulphide. This carbon may be obtained from the decomposition of hydrocarbons in the gas, but analyses of the gas made before and after treatment, which are given below, show that the quantity so decomposed is negligible.

No information has been given as to the cost of operating this process, and although it does not require the maintenance of as high a temperature as is employed in the Hall and Papst process it would seem to be somewhat more complicated and expensive, even though no loss of nickel be suffered.

Another process which has only been tried at an experimental plant of the Heidelberg, Germany, Gas Works, consists in treating the gas, entirely freed from tar, ammonia, sulphuretted hydrogen, and carbon dioxide, with a compound of soda and cellulose obtained by treating cellulose sulphite with soda lye. The resulting material, after having been rolled and crumbled to a powder, is placed on trays in purifying vessels in the same way as oxide of iron. When brought into contact with carbon bisulphide the soda cellulose is changed into cellulose xanthogenate or viscose, the raw material from which are obtained cellulose hydrate and the formyl-cellulose used in the manufacture of non-inflammable celluloid. In the experimental plant ten tons of the soda cellulose material, known as "Athion," absorbed 1·25 tons of carbon bisulphide, so that with gas containing 45 grains per 100 cu. ft., ten tons would purify over 35,000,000 cu. ft. of gas, but the cost of operation is not given.

Since it is not the custom in the United States to remove carbon dioxide from illuminating gas, the employment of this process would involve the installation of additional apparatus for that purpose.

A very promising process, which, however, has not yet been tested on a working scale, is based upon the fact that at temperatures above 100° F. metallic iron acts as a catalyst that brings about and accelerates the reaction between bisulphide of carbon and moisture in illuminating gas. The fact that gas, free from sulphuretted hydrogen originally, contained this substance after having passed through a wrought iron service pipe which, because of running near a steam pipe, was heated to temperatures varying between 90° and 158° F., attracted the attention of Mr. J. G. Taplay, and a number of experiments made by him showed that at a temperature of 158° F. the reaction between the bisulphide of carbon and moisture with the formation of sulphuretted hydrogen took place quite rapidly in gas travelling through a wrought iron pipe, and also that as the interior of the pipe became rusted the sulphuretted hydrogen produced was absorbed by the oxide of iron and did not show at the outlet of the pipe.

A French gas engineer, M. Guillet, observed the same action taking place inside a gasholder, and by experiments determined that when gas containing bisulphide of carbon was passed through ordinary oxide of iron purifying material at temperatures above 25° C. (72° F.) 25 per cent. of the original content of carbon bisulphide was removed. He found 100° C. (212° F.) to be the temperature at which the change became interestingly rapid, while at a temperature of 130° C. (266° F.) more than 67 per cent. of the bisulphide of carbon originally present was converted into hydrogen sulphide and removed as the gas passed through the material. The percentage removed increased with the amount originally present, the treated gas containing only from 3·01 to 5·82 grains, while the original gas contained from 9·48 to 24·42 grains of bisulphide of carbon per 100 cu. ft.

Since the efficiency of oxide of iron for the removal of sulphuretted hydrogen is very much increased by heating and it should not be difficult to maintain the temperature of the purifying material at the comparatively low temperature of, say, 250° F., this process would seem to offer the simplest and most inexpensive means of removing from illuminating gas the larger portion of the bisulphide of carbon which it still contains after the treatment ordinarily given to it in gas works, whenever the amount of this impurity present is sufficiently large to make it important that it should be reduced.

Yorkshire Section.

Meeting held at the University, Leeds, on Monday, January 26th, 1914.

MR. GEO. WARD IN THE CHAIR.

CORROSION BY DISSOLVED OXYGEN.

BY PROF. J. W. COBB AND G. DOUGILL.

It has long been recognised that the presence of dissolved oxygen in water is practically certain to increase its corrosive action on iron, whether by its depolarising action (the electrochemical view) or in some other way. On the other hand, data are not available, so far as the authors are aware, to demonstrate how far this action goes in practice, whether a negligible, a small, or a large proportion of the dissolved oxygen is likely to combine with the iron in any ordinary water system, particularly when the water is being subjected to heat and so to increasing inability to hold the oxygen in solution. For this reason it is notorious to those concerned with actual practice in these matters, that the consideration given to the possible effect of dissolved oxygen, when water-heating plant is designed and erected, is usually of a cursory kind. Our results were obtained in connection with an industrial problem, and are published by consent. Their theoretical interest is small, but it is hoped that they may be useful practically. They illustrate to what a marked extent the phenomenon in question may be manifested in an ordinary water-heating apparatus.

The object of the series of experiments was to determine the extent to which dissolved gases might be responsible for extensive rusting in hot water pipe systems. Such an inquiry seemed very necessary because several cases of such rusting had come to the notice of one of us, when the water was satisfactory to the ordinary chemical tests, and there was no reason to suspect abnormality in the iron. For this purpose an apparatus was set up (Fig. 1) in which to some extent conditions of practice were reproduced.

The iron pipe shown was 6 ft. long and 1 in. internal diameter, heated by a small tube furnace. Water was fed from a constant-head apparatus, open to the atmosphere, into the lower end of the iron pipe, passing on its way through a bottle which acted as an air-trap. The rate of flow was controlled by the insertion of a glass tube drawn down to a jet, in the inlet connecting length before the iron tube. The average rate of flow was 10 litres per 24 hours, and the pipe held 0·93 litre, so that the water was about 2¼ hours in the pipe before coming out at the upper end. There it passed through a gas holder, where any liberated gas collected, through a guard bottle, D, and finally out by a long glass capillary tube into a measuring cistern.

The water entered at air temperature, was near boiling point on reaching the thermometer bulb 5 inches up the tube, and averaged 65° C. on leaving. Daily tests were made of the quantities of water passed and gas collected in the 24 hours, and oxygen contents of inlet and exit water and gas were determined. The methods of determining the oxygen dissolved in the water are appended. Gas analyses were made in the Hempel apparatus. A colorimetric method was used for determining the dissolved and finely suspended iron, which coloured the exit water decidedly red-brown when air-saturated water was used. A description of this method is also appended.

The apparatus was run for some time in this way, and then, as a sort of blank test, was run with air-free instead of air-saturated water. By-passed bottles were found necessary for obtaining water samples without possibility of air contact. The results of the run on air-free water are given in Table II., and those on air-saturated water in Table I.

The air-free water was prepared in the apparatus shown in Fig. II. J, a vessel of 5—6 litres capacity, was exhausted by a water pump to about 30 mm. mercury pressure. Water was boiled in the flask, A, and the steam and expelled gases passed out at B into the beaker, E, which was thereby raised to boiling point. After A had boiled for 10 minutes, the water was drawn through the cooling worm, W, into J. When the flask, A, was nearly empty, the tap, H, was closed and the bunsen removed. This caused the steam in A to condense, and drew in a fresh charge of hot water from E. By repeating the process air-free water was accumulated in J. In the blank run this

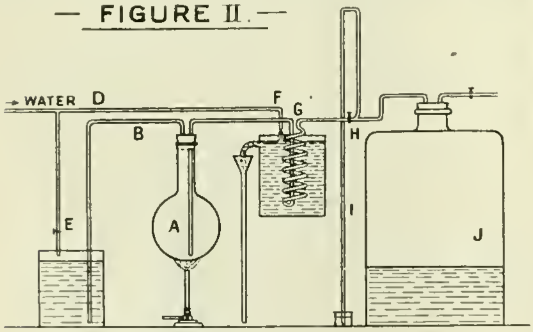
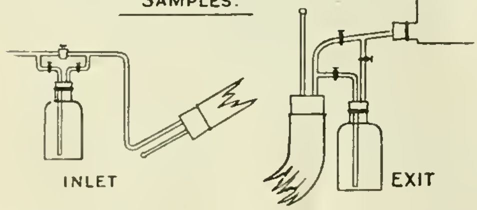
water was driven through the heating apparatus by compressed nitrogen from a cylinder. The results showed that with air-free water very little oxygen entered the heating apparatus, and since no gas was collected at the upper end, was presumably absorbed by the metal. Incidentally, the iron in the exit water, determined by the colourimetric method, was smaller than with air-saturated water, but this result was of little significance, as the amount would depend partly on agitation detaching rust from the walls.

— FIGURE II. —



— ARRANGEMENT FOR BYPASSING — SAMPLES.



After the first run lasting about 3 weeks, and before using air-free water, the iron pipe was taken down and examined. The accumulation of chocolate-coloured rust in the lower end of the pipe was plain proof of extensive rusting.

A simple interpretation can be placed on results given in Table I. The gases dissolved in cold water if simply expelled would contain 30 per cent. oxygen. The gas collected after passing through the tube contained only from 5—10 per cent. of oxygen. Moreover, the oxygen in the exit water and gas together, easily calculable from the experimental results, was only a fraction of the total oxygen dissolved in the water entering. This was plainer from experiments made later for the express purpose of obtaining a balance. The results obtained were in agreement with those already given (see Table III.).

The loss of nitrogen is disregarded as being within the limits of probable experimental error. The loss of oxygen presumably represents oxygen which has been absorbed by the metal forming oxide rust. It represents 95 per cent. of the total oxygen dissolved in the inlet water. The loss of CO_2, also presumably absorbed by the iron to form rust, represents 30 per cent. of that originally present.

Since the dissolved gas was likely to be expelled on boiling in the first length of the iron pipe, it was interesting to know what would be the effect if the gases were as far as possible removed by some method just after heating. For that purpose the apparatus was altered as shown in Fig. III.

One foot from the lower end of the sloping tube was inserted a piece of thin sheet iron, and a length of iron tubing was tapped into the main tube so as to stand vertically immediately below the inserted strip. Gas evolved from the water on heating was trapped by the inserted strip and collected in the vertical tube. Water at this point was drawn off by a vertical glass tube connected with a sampling bottle.

Air-saturated water was run through the apparatus and results are given in Table IV. A typical result was as follows :—

O_2 entering.	O_2 collected at lute.	O_2 in water at lute.	O_2 in exit water and gas.
6 c.c./lH_2O	3 c.c./lH_2O	nil	all

This indicated that about half the originally dissolved oxygen had been absorbed by the pipe in the first foot length of the tube. The remainder was collected as gas at the lute, and air-free water passed up the rest of the apparatus, *i.e.*, no rusting from the action of dissolved oxygen in the water-supply could take place beyond the lute.

*Average of a large number of readings = 3·0 c.c. O_2/litre.

When the gases were not separated at the lute, most of the remaining oxygen was absorbed in the further length of the tube.

Up to 5 per cent. of CO_2 was found in gas collected at the lute, and practically none in the water, but when no lute was used 2/3 of the CO_2 originally present was found in the exit water, and none in the gas, indicating extensive re-solution of CO_2 in the cooler end of the tube beyond the heated portion and lute.

The following results were obtained from an experiment in which the gas was collected at the lute (see Table V.).

TABLE V.

	O_2 c.c.		CO_2 c.c.		N_2 c.c.
Dissolved in 1 litre of inlet water	5·9		1·7		15·3
Dissolved in 1 litre of water at lute	0·0	3·0	0·1	1·3	0·5
Gas accompanying 1 litre of water at lute	3·0		1·2		14·8 (diff.)
Absorbed by iron between inlet and lute (by diff.)	2·9		0·4		—

Summarising the results so far obtained, the actions indicated as taking place are as follows: Cold water enters and is raised to boiling point. The dissolved gases are liberated, and about half the oxygen present is absorbed by the tube. At a point one foot from the lower end of the tube the system consists of

(1) Gas-free water.

(2) Gas containing (*a*) all the nitrogen; (*b*) most of the CO_2; (*c*) half the oxygen originally dissolved.

If the gas is tapped off here a large amount of rusting during the rest of the tube due to oxygen and CO_2 is avoided. If it is left to pass up the tube most of the oxygen unites with the iron, while some nitrogen and all the residual CO_2 are redissolved in the exit water. In any case, about half the oxygen and a small proportion of CO_2 are absorbed by the metal of the tube in the heated length. (Much less stress is laid on the CO_2 than on the oxygen results; they are deduced from a very much smaller number of experiments.)

TABLE VI.

Time in mins.	Temp. °C.	Conditions.

60	91	" " " and very little gas rising.
105	91	Surface covered with rust and no gas rising.

It was therefore made plain that a considerable amount of rusting from dissolved oxygen could be avoided by mechanical removal of the gases evolved at the end of the heated length, before the water came into the rest of the system. It also appeared that considerable absorption of gas and rusting took place in the heater itself. We decided to see how far the action was manifested on a still smaller scale, and whether the destruction of dissolved oxygen by simple chemical means was useful. The following experiments were made.

A litre flask was fitted with a cork, holding a capillary tube to allow for expansion, a glass hook, and a thermometer. A small piece of Kahlbaum's pure iron foil was suspended from the glass hook. The flask was filled with tap water, and left for 1¾ hours on a steam bath. Table VI. shows the progress of the experiment. Rusting was extensive.

Another similar flask was filled with water, and boiled to expel the gas. The foil was suspended in it, and left on the steam bath alongside the first. No gas bubbles appeared, and no rusting. Preliminary removal of oxygen by boiling is then an effective means of minimising rusting.

Removal of oxygen by chemicals.

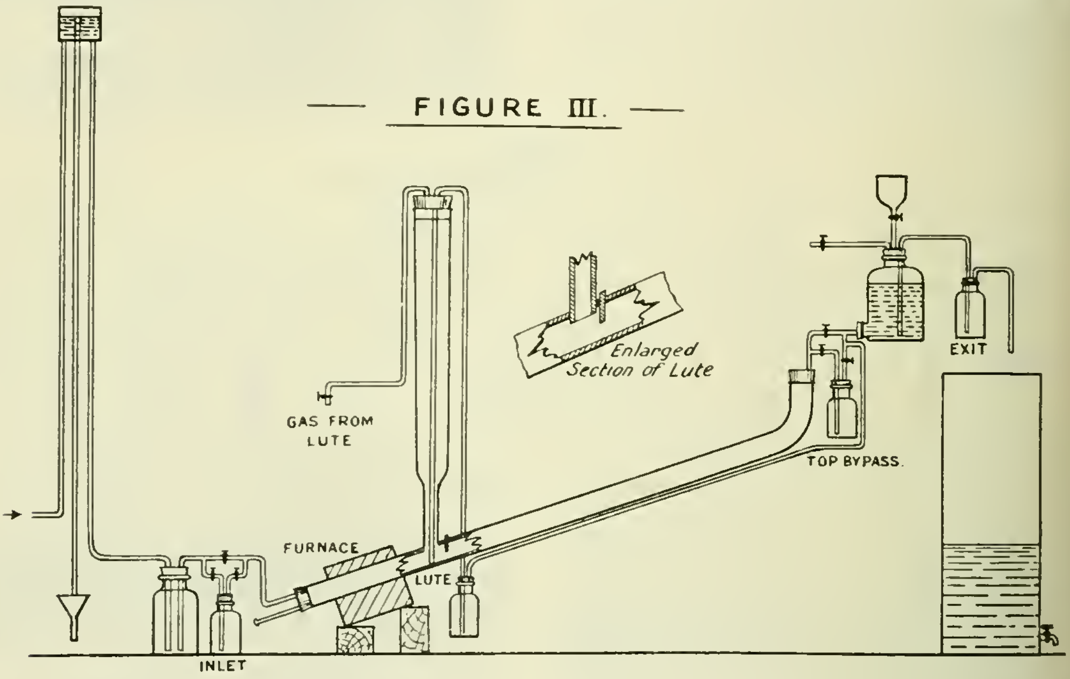
The next experiments were made with chemicals which would themselves take up the dissolved oxygen, and the first tried was sodium arsenite, of which 0·11 grm. per litre of water (the quantity theoretically required) was used.

The sodium arsenite was added to the cold air-saturated water, which was then heated in contact with pure iron foil as before. The rusting was decidedly lessened. The proportion of sodium arsenite was then varied by stages from 50 per cent. of the theoretical to three times the theoretical quantity. The rusting was reduced with increasing quantities of arsenite to a very small amount, but not entirely prevented. The results were interesting, but in order to test materials which were possible in practice on the large scale, a mixture of sodium hydroxide and ferrous sulphate was added in the proportions necessary to take up the dissolved oxygen according to the equation :—

$$4NaOH + 2FeSO_4 = 2Na_2SO_4 + 2Fe(OH)_2.$$
$$2Fe(OH)_2 + O_2 = Fe_2O_2(OH)_2.$$

Commercial caustic soda and green vitriol were used. On adding the substances separately in solution a bulky green precipitate formed, which rapidly turned reddish-brown and settled to the bottom of the flask. The prevention of rusting was found to be nearly but not completely effected by theoretical quantities. The cost of chemicals for such a treatment, which may often be practicable, especially as a finishing process in the elimination of oxygen, would be 2d.—2½d. per 1000 gallons for an ordinary water containing 6—7 c.c. of oxygen per litre: 1·3 lb. caustic soda and 4·5 lb. ferrous sulphate, quantities 20 per cent. in excess of the theoretical, are here assumed necessary, and the whole of the dissolved oxygen is supposed to be treated.

FIGURE III.



Summarising, we found :—

(1) That in our experiments a very large proportion of the dissolved oxygen in the water supply, used for a simple heating system consisting of one pipe, was not present in the water or gas leaving, but had been absorbed in the pipe. It was presumably used up in rusting the iron, and a large quantity of rust was actually formed.

(2) That about half the loss of oxygen occurred in the first foot length of the pipe—the heater.

(3) That the further loss of oxygen occurred in the 5 ft. of pipe beyond the heated length, and could be prevented if the expelled gases were mechanically taken off at the end of the heated length.

(4) That in small scale experiments with pure iron foil the expulsion of dissolved gas from the water by previous boiling was an effective means of preventing rusting.

(5) That in similar small scale experiments it appeared that the rusting of iron foil could be almost prevented by treating the cold air-saturated water with the sodium hydroxide and ferrous sulphate necessary to take up the oxygen dissolved in the water supply.

Appendix on methods of analysis.

The following were used :—

(1) The gasometric method described in Lunge and Keane's Technical Methods of Analysis, Vol. I., p. 776. This method depends on the expulsion of dissolved gases by CO_2; the gases are collected over caustic potash and, of course, any CO_2 dissolved in the water is not estimated.

(2) Winkler's titration method. In this well-known and widely-used method the power of manganous hydrate for taking up oxygen is utilised. Only oxygen is estimated. Methods (1) and (2) were compared on the waters used and gave identical results.

(3) The gases were boiled off the water, collected over mercury, measured and analysed. This gave all the dissolved gases.

The following method was used for the determination of dissolved and finely suspended iron compounds.

50 c.c. of the water, containing 1 c.c. of strong nitric acid, were brought to boiling point and kept hot for 1 hour. This was necessary to ensure complete solution of suspended iron oxide. 5 c.c. of the cooled solution were poured into a graduated comparison tube with 2 c.c. of potassium thiocyanate, and 5 c.c. ether added to extract the red compound. After shaking, the colour of the ether was compared with that obtained with a standard solution. This standard was made by running into 2 c.c. of potassium thiocyanate and 5 c.c. of ether an iron solution of known strength from a burette until the ether layer was about the same colour as the layer in the other tube. Distilled water was added until the volumes were equal, and then a little more iron solution to make the colours match exactly. The iron solution was made by dissolving 0·1 grm. of iron wire in sulphuric acid, oxidising by nitric acid and making up to 1 litre. 5 c.c. were diluted to 500 c.c. as required. 1 c.c. of solution = 0·000001 grm. iron. To match the colour usually produced about 2·5 c.c. of iron solution was required.

DISCUSSION.

Mr. G. **Ward** asked whether the nature of the iron of the pipe used for the experiment was at all comparable to th cast iron tubes employed in heating apparatus. He supposed it would be a piece of gas tubing, which was ver different to the tubing used by water engineers. Probabl the cast iron pipes used by engineers were very much les liable to corrosion.

Mr. J. **Miller** said that when engineers used condense water they expected to have little or no corrosion, as th water contains no dissolved solids. However, the con denser water got thoroughly mixed with air, and extensiv corrosion occurred. If means were taken to prevent ad mixture of air, no corrosion took place.

Dr. **Meyer** said that when water contained not more tha 5 c.c. of dissolved oxygen, his experience was that the was very little corrosion. When 5·5 c.c. of oxygen were present, there was some corrosion, whilst if there were between 20 and 30 mgrms. of free carbonic acid present with 5·5 c.c. of oxygen, there was very great corrosion. He would like to know the limit. He would also like to know whether Professor Cobb included all the organic acids in his free CO_2, as he had found that when 1 to 2 or 3 c.c. of organic acids were present, the water was very corrosive.

Mr. W. G. **Young** asked as to the condition of the iron pipe before the experiment. Was it cleaned or burnished, or was it simply a piece of rough gas piping. Was any attempt made to weigh roughly the iron oxide formed. Under the conditions of the experiment he supposed that some of the oxygen would be used up by the organic matter, as all water contained organic matter. Would it be possible to use some simple mechanical means to get rid of the dissolved gases before the water entered the boiler ?

Dr. **Meyer** said that if a water contained 6 c.c. of dissolved oxygen per litre, it was possible to bring it down to 2 c.c. by heating to 60° C. Would it be possible to do this first, and then to put soda and ferrous sulphate into the boiler. Also did Prof. Cobb agree to use manganese permutite to remove the last trace of iron, after removing the oxygen by means of soda and ferrous sulphate.

Mr. C. P. **Finn** asked if the oxide produced was removed mechanically by the flow of the water up the pipe, or did it remain more or less as a firm coat. In either case was corrosion continuous, or did it reach a point when it began to be less. Pointing out that the conditions which existed in the experiments were similar to those in the case of economisers, he asked whether the authors could say to what extent economiser pipes suffered.

Dr. H. T. **Calvert** asked whether the amount of corrosion increased with increasing amounts of oxygen in the feed water. One would imagine oxygen would readily escape with the steam. A large excess of ammonium thiocyanate was necessary to obtain the maximum colour in the method used for estimating iron. This, he presumed, had been taken into account in the estimation.

Mr. **Rushby** did not think that corrosion would take place to the same extent with cast iron tubes as with those made of wrought iron. What was the reaction when a slight excess of an alkali carbonate or hydroxide was added to a water to prevent corrosion. He thought corrosion was due not so much to the oxygen alone, as to the oxygen plus acids. For instance corrosion could be avoided by adding seaweed extract ; also by adding an alkali. He had noticed that corrosion took place most extensively along the seating of a boiler, which is the coolest part. Could Professor Cobb explain this. He also pointed out that boilers worked under high pressures, and this would probably modify the results.

Prof. **Cobb**, in reply, said that the nature of the metal would no doubt influence its corrosion as suggested. Their experiments were made with a wrought iron tube. Small cast iron pipes were almost unknown, but larger sizes were, of course, extensively used. It was inadvisable to assume that cast iron necessarily corroded less than wrought iron. The "skin" of cast iron had a protective influence, but when that was removed, as by machining, the exposure of graphite and iron and carbide opened the way to electro-chemical action. In confirmation of Mr. Miller's remarks, he said that in a particular case which had come to his notice one set of pipes carrying condensed water, freed from air, suffered no corrosion, while another set, fed with the same water, air-saturated for make up, was badly corroded. They had not studied possible corrosion due to peat acids. Reducing the dissolved oxygen by a preliminary heating to about 60° C. and treating chemically to remove the rust, seemed to be a promising way of working in practice. Treatment with manganese permutite would apply particularly to the removal of that small proportion of the oxidised iron which had gone into solution. The pipe used was ordinary wrought iron steam pipe, and was not prepared in any way. Attempts to weigh the rust formed had been made, but were useless. Most of the oxide remained attached to the iron pipe. The organic matter in the water might be responsible for the destruction of a small portion of the dissolved oxygen. But the heating or boiling of waters in the ordinary process of estimating organic matter with permanganate would seem to indicate that any error arising from this cause would be small. In the colourimetric process for estimating iron, a large excess of thiocyanate was present. The use of alkali to lessen corrosion due to acid in water, was no doubt of service. Corrosion along the seating lines of a boiler was, so far as he knew it, external, and was probably due to low temperature and "pocketing" of the flue gases along those lines.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows :—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows : Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.) ; Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT ; MACHINERY.

Patents.

Refrigerating apparatus. E. C. R. Marks, London. From The Iceless Refrigerator Co., Chicago, Ill., U.S.A. Eng. Pat. 27,598, Nov. 30, 1912.

The apparatus consists of a pair of vessels each of which acts alternately as a generator or an absorber of, for example, ammonia vapour. Heating and cooling devices are mounted on a rocking frame so that they can be changed over and the functions of the vessels reversed as required. The reversing gear is controlled by devices in the vessels sensitive to heat and pressure.—W. H. C.

Separation of impurities from liquid by centrifugal force ; Method of and apparatus for ——. J. Hamill, Liverpool. Eng. Pat. 6333, Mar. 14, 1913.

The centrifugal is divided horizontally into compartments wherein the suspended impurities, respectively denser and lighter than the liquid itself, may be separately and successively removed.—J. L. F.

Incrustation in boilers and the like ; Prevention of ——. I. Radaeff, Moscow. Eng. Pat. 11,354, May 15, 1913.

A mixture of sodium hydroxide, sodium carbonate, tannin and tannin extracts and a mucous vegetable substance obtained by boiling linseed, Iceland moss or similar bodies with water is introduced into the boiler.—W. H. C.

Charging and discharging retorts, muffles and the like. R. von Zelewski, Engis, Belgium. Eng. Pat. 12,120, May 24, 1913. Under Int. Conv., May 31, 1912.

A scraper with a series of equally spaced blades has a working stroke equal in length to the space between successive blades, so that the muffle, etc., may be gradually charged or discharged by a succession of strokes of the scraper.—J. L. F.

Drying apparatus; Air or gas supply arrangement for ——. W. P. Thompson, Liverpool. From A/S. Myrens Verksted, Christiania. Eng. Pat. 21,276, Sept. 20, 1913.

In apparatus for drying boiled crang (whale flesh), and the like, a series of superposed, concentric, cylindrical chambers is used, over the bottoms of which a series of arms carrying scrapers or knives revolve on a vertical shaft, so as to loosen and disintegrate the material. Drying and heating gas or air is admitted through the central hub of the scrapers, through the rear of the latter, and thence through the hub of the set of scrapers in the chamber immediately above, and so on from chamber to chamber.—J. L. F.

Drying chambers. E. C. R. Marks, London. From The Cutler Dry Kiln Co., Inc., New York. Eng. Pat. 22,985, Oct. 11, 1913.

Air enters and leaves the drying chamber through one or more porous walls and is forced through the interstices of the heat-radiating device by a fan fixed within the chamber.—W. H. C.

Drying apparatus. W. J. Elsworth, W. H. Allen and O. Elsworth, Newcastle-on-Tyne. Eng. Pat. 25,956, Nov. 12, 1913.

The heating furnace is enclosed by a casing which conveys hot air to the drying chamber. The latter contains the furnace flues, which terminate in a chimney surrounded by the annular duct discharging the moist air. By reducing the area of the moist air outlet to less than that of the dry air inlet, a small increased pressure can be obtained in the drying chamber.—J. L. F.

Desiccating and collecting apparatus. I. S. Merrell, Assignor to Merrell-Soule Co., Syracuse, N.Y. U.S. Pat. 1,088,436, Feb. 24, 1914.

The material is forced by a current of air into one end of a desiccating chamber having a number of collecting chambers at the opposite end, each fitted with a filter and a valve. Some of the dried dust falls to the bottom of the chamber where it is carried forward on a travelling conveyor to a discharge outlet at the side, while the dust which collects on the filters is caused to drop on to the conveyor from time to time by closing the outlet valve of any one collecting chamber to prevent air from passing, and shaking the filter.—H. H.

Conveying and mixing slurry, mud, sludge and the like; Method of and apparatus for ——. O. Polysius, Dessau, Germany. Eng. Pat. 21,481, Sept. 23, 1913.

The compressed air used for conveying the mixture also serves for stirring it, a number of similar holders being arranged so that as one fills, a second is emptied, and a third, which has been emptied, is connected with a compressed air collector, in which the pressure of the air is reduced to render it suitable for agitating the mixture in the storage tank. The holders, fitted with automatic inlet and outlet valves, are supplied from a constant level feed-tank, or tanks, and are successively placed into communication with the delivery, the air collector and the atmosphere by means of three-way cocks operated by floats. The surplus air, if any, is discharged when the holder is connected to the air prior to filling. The agitation is effected by means of an air-lift device, consisting of a vertical pipe connected with the exhaust air collector at its lower end, open at both ends, and perforated or slotted to permit of its working independently of the height of the mixture to be agitated.
—J. L. F.

Pumping or raising liquids; Method of and apparatus for ——. H. J. Mellis, London. Eng. Pat. 22,012, Sect. 30, 1913.

To overcome the difficulty of accurately timing the periodic application of pressure to a column of liquid caused to oscillate by means of an elastic body, (usually a gas or air pocket), to which it is connected at its lower extremity, floats, pistons or the like, operated by the movements of the column of liquid are provided, and mechanically connected with suitable valves in such a way that the periodic application of pressure is dependent upon the movement of the oscillating column.—J. L. F.

Grinding, crushing, pulverising and the like; Roller and ring mills for ——. J. Y. Johnson, London. From Gebr. Pfeiffer, Kaiserslautern, Germany. Eng. Pat. 24,822, May 8, 1913.

The grinding rolls and rings are supported by flexible bearing awhich move in relation to the grinding ringa, radially, and to the rolls, axially.—W. H. C.

Furnaces provided with regenerative chambers. H. Poetter and Poetter, Ges. m. b. h., Düsseldorf, Germany. Eng. Pat. 26,411, Nov. 18, 1913.

A slide which runs on rails and moves across the flues leading to the regenerative chambers, has three ports, of which the central one is always used for supplying air for combustion, whilst the two outer ports alternately conduct the waste gases to one of the two regenerative chambers and the air to be preheated to the other.—J. L. F.

Furnace for baking refractory earths. A. Valuy. Fr. Pat. 463,574, Oct. 13, 1913.

A calcining furnace for refractory earths heated by cheap fuels such as lignite, is formed with a central calcining chamber having a furnace at one side. The furnace gases enter the calcining chamber through a horizontal passage at the top and are deflected downwards by a curved roof or partition separating the calcining chamber from a chamber above it which acts both as a flue and as a drying chamber for the refractory earth. The air supply passages are in the heated walls of the furnace.—H. H.

Catalyser and process of making same. C. Ellis, Montclair, N.J. U.S. Pat. 1,088,673, Feb. 24, 1914.

Finely divided carbonaceous or other porous granular material is impregnated first with a precipitant of nickel and then with a solution of a nickel salt, in such proportions that not more than 15 per cent. of "nickel material" is precipitated.—H. H.

Coating objects with subdivided material; Process of ——. F. F. Bradley, Assignor to Bradley and Vrooman Co., Chicago, Ill. U.S. Pat. 1,088,874, Mar. 3, 1914.

Bodies having a multiplicity of surfaces to be coated wit subdivided material are first coated with adhesive materia and then placed in the centre of a chamber into whic opposing streams of gas carrying the finely divided coatin material in suspension are projected.—H. H.

Evaporator. J. T. Wann, Berkeley, Cal. U.S. Pa 1,089,027, Mar. 3, 1914.

A series of racks carrying trays for fruit, etc., is arrange in the upper part of a chamber with vertical inlet an outlet flues for hot air between the racks. The tray are inclined upwards from the inlet to the outlet flue and the inlet flues are fitted with deflectors to direct t hot air between the trays.—H. H.

Evaporating apparatus for all kinds of liquids. E. Barbet. First Addition, dated Dec. 26, 1912, to F Pat. 461,890, Nov. 8, 1912 (this J., 1914, 188).

The envelope enclosing the tubes is made cylindric instead of pyramidal. This arrangement is to strength the apparatus and make it possible to have two removal ends, so as to facilitate cleaning.—N. C. A.

Dried or concentrated products; Process for obtaini without loss ——. G. A. Krause. Fr. Pat. 463,3 Oct. 6, 1913. Under Int. Conv., Oct. 12, 1912.

The finely-divided particles carried away when substan in the form of spray are evaporated or dried by a curr of hot air or other gas are caused to deposit by the action of a high-tension electric current. The wall of the metallic containing vessel, or a metallic lining or plates suspended in the vessel, may form one electrode, the other being fine wires or wire gauze. Ozone or oxides of nitrogen may also be produced by the current whereby the product is bleached or otherwise modified.—N. C. A.

Separating fluids having different characteristics; Method and means for ——. C. S. Brown, Nashville, Tenn. U.S. Pat. 1,089,187, March 3, 1914.

The fluids are caused to flow through an orifice in a plate or other surface and then to spread out in a thin film between the surface and a thin plate movably supported upon the surface. The passage between the plate and surface rapidly increases in area as the fluid moves away from the orifice and the pressure in the passage varies correspondingly but is different for different fluids. The distance between the plate and surface adjusts itself automatically so that one fluid is able to escape whilst the escape of the other is substantially prevented.—H. H.

Grading powdered material; Apparatus for ——. Comp. de Fives-Lille and P. Habets and A. France. Fr. Pat. 463,864, Oct. 21, 1913.

The material (fine coal, ores, grain, etc.) is fed from a hopper by a rotating feeder, into a chamber in which it is submitted to an upward blast of air, which carries with it the finer particles. The heavier particles fall into an hydraulic seal at the bottom of the chamber from which they can be continuously removed without disturbing the air pressure. The intensity of the blast and the size of the outlet through which the air carrying the fine particles escapes are regulated by valves. The plant can be used as a unit or in batteries.—N. C. A

Crystallisation of hot saline solutions; Continuous ——. Häberlein. Ger. Pat. 271,102, June 18, 1912.

The quantity of cooling liquid supplied to the different compartments or groups of compartments of the crystallising vessel is progressively diminished so as to ensure that the requisite conditions in regard to fall of temperature and temperature difference between cooling surface and solution are maintained in the different parts of the apparatus.—A. S.

Drying apparatus; Shaft or tower ——. A. Huillard, Suresnes, France. Eng. Pat. 17,521, July 30, 1913.

See Fr. Pat. 461,612 of 1913; this J., 1914, 187.—T. F. B.

Desiccating fluid substances; Method for ——. W. B. McLaughlin, New York. U.S. Pat. 1,090,740, March 17, 1914.

See Fr. Pat. 441,742 of 1912; this J., 1912, 947.—T. F. B.

Separating mixtures of gases. A. Sinding-Larsen, Christiania. U.S. Pat. 1,091,023, March 24, 1914.

See Eng. Pat. 8211 of 1910; this J., 1910, 1092.—T. F. B.

Filter plate. P. Porges, Vienna, Assignor to L. Steinschneider, Brünn, Austria-Hungary. U.S. Pat. 1,091,080, March 24, 1914.

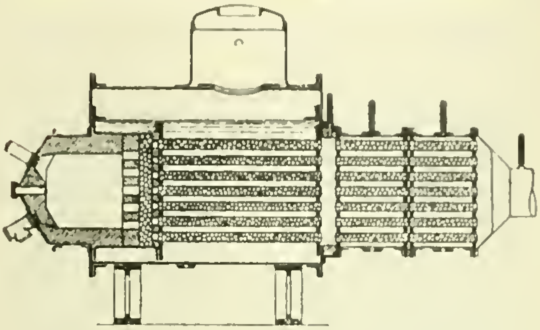
See Eng. Pat. 12,737 of 1912; this J., 1913, 740.—T. F. B.

Method and apparatus for expressing oil from seeds, nuts, and other oleaginous substances, and juice or fluid from fruits, herbs, flowers, peat, etc. Eng. Pat. 29,331. *See* XII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Flameless surface combustion. O. Dobbelstein. Stahl u. Eisen, 1914, 34, 561—578. (See also this J., 1911, 527; 1912, 61, 524; 1914, 303.)

Details of tests of the "Bonecourt" boiler installed at Krupp's works are given. Considerable difficulty was experienced on account of the strong corrosion of the tubes and clogging of the material with which they were packed, mainly due to the sulphur contained in the coke-oven gas.



In every test several of the tubes did not work satisfactorily, and with the present arrangement it was difficult to ensure equal distribution of, and resistance to, the gas in all the tubes. The Berlin-Anhaltische Maschinenbau A.-G. have constructed a small experimental boiler, fired with tar-oil, embodying certain features (see Fig.), designed to eliminate this difficulty of unequal distribution, etc. This boiler on test evaporated no less than 26·3 lb. per sq. ft. of heating surface per hr.—about twice the rate of the Krupp boiler—with a heat-efficiency of 0·90, and a net efficiency of about 0·82. Existing designs of this type of boiler did not prove suitable to he demands of practical steam-raising.—J. L. F.

Flame; Initiation and propagation of ——. H. B. Dixon. J. Gas Lighting, 1914, 125, 819—822.

Experiments by Falk (this J., 1908, 324) in which a mixture of gases was heated by sudden compression by a falling piston in a steel cylinder, appeared to indicate that the mixture of oxygen and hydrogen most easily ignited was one of equal proportions of the two gases. In these experiments the greatest depth reached by the piston before it was shot upwards by the force of the explosion was observed, it being assumed that since the whole gas column was compressed and heated to the ignition point, the flame would spread through the gas as an explosion wave, and hence the time elapsing between the initiation of the flame and the reversing of the motion of the piston could be neglected. Using a method of photographic analysis the author found that when the gases were compressed to the ignition point and the movement of the piston then artificially arrested, a flame appeared at some spot in the heated gas after an interval and spread slowly throughout the mixture. The flame did not start as an explosion wave, though it quickly set up such a wave in a sensitive mixture such as electrolytic gas. In the case of the latter mixture the pre-flame period was short and would not appreciably affect the results obtained by Falk, but with a mixture containing 3 vols. of oxygen to 1 vol. of hydrogen. it was so prolonged that the piston moved in a considerable distance after the "ignition point" was reached, and an appreciable distance even after the flame appeared. The duration of the pre-flame period of combustion varied with different gases; it was remarkably prolonged in the case of methane. It was only in this initial stage of combustion that the influence of water vapour was exerted: pure mixtures of hydrogen or a hydrocarbon and oxygen were ignited by a spark however thoroughly they were dried, and the flame was propagated more rapidly than when water vapour was present. The ignition point of a gaseous mixture may be accurately determined by compression in a steel cylinder by a falling piston provided with a head-piece which is arrested at the desired moment by a collar through which the piston-rod passes. Successive trials are made, with increasing compression, till the mixture fires. The values so obtained are lower than those determined at atmospheric pressure, *e.g.*, 526° C. as compared with 585° C. in the case of electrolytic gas.

The possibility of determining the specific heats of gases at high temperatures by measuring the velocity of sound therein is discussed and some experiments in this direction are described.—A. S.

Producer gas; Chemical changes occurring during the passage of —— through pipes. E. Schmatolla. Chem.-Zeit., 1914, 38, 409—410.

When an installation of gas-fired furnaces or retorts is first set to work, the gas conduits become thickly coated with a mixture of tar and soot which can only be removed by laborious scraping, or by burning. After normal working conditions have been reached, the conduits require cleaning only at long intervals, and only soot is deposited, which can easily be removed by admitting a blast of compressed air into the conduit, which should for safety be above the ignition temperature. The deposit formed at first is produced by the adherence of soot to the tar which condenses on the cold walls of the new conduit, and at temperatures of about 450° C., the gas is partially decomposed with deposition of more carbon: $2CO+C=CO_2+2C$. The reverse reaction which occurs at 700°—800° C. can be used for partially cleaning out the conduits, the supply of fresh coal to the producer being interrupted so that a very hot gas is passed through the conduits.
—A. T. L.

Carbonising chamber for gas-works; New type of ——. The Koppers combination oven. G. S. Cooper. J. Gas Lighting, 1914, 125, 813—815.

The oven can be used as a gas-oven heated entirely by producer gas or as a coke-oven heated by part of the gas produced from the coal: the change can be made in a very short time and without interfering with the working of the oven. The oven is provided with divided regenerators and with a distribution pipe for supplying gas to the heating flues direct. When used as a coke-oven, all the regenerators serve for preheating the air, the coke-oven gas used for heating being supplied direct to the heating flues. When used as a gas-oven, one pair of regenerators serves to preheat the air and the other the heating gas (producer gas or blast-furnace gas). When using the oven as a coke-oven, benzol may be recovered from the portion of the gas used for heating purposes. Installations of 35 of these combination ovens have been in operation for some time at Koenigsberg, Germany, and at Joliet, Ill., U.S.A.—A. S.

Self-ignition temperature of motor oils; Determination of the ——. E. J. Constam and P. Schläpfer. Les Matières Grasses, 1914, 7, 4037—4042. (See also this J., 1913, 1096.)

A small crucible is imbedded in calcined silica in a larger platinum crucible, through the cover of which is passed a platino-rhodium thermo-element and a tube for admitting a current of oxygen or air. When the required temperature is attained, a drop of the oil is introduced, and this is repeated at gradually increasing temperatures until ignition takes place. A sharp explosion in a current of oxygen or a dull explosion in air occurs at the moment of ignition. The following results were thus obtained in the examination of 117 samples of oils:—Diesel motor naphthas, 300° to 350° C.; Borneo liquid fuel, 400° C.; creosote oil, 550° C.; and arachis and palm oils, 400° C.
—C. A. M.

Gasoline from natural gas in the United States. U.S. Geol. Survey. Oil, Paint, and Drug Rep., March 30, 1914. [T.R.]

The number of gasoline plants in operation in the United States increased from 176 in 1911 to 250 in 1912, and the daily capacity almost doubled. These figures included the regularly established compressor plants, also those which use the simple method called the "gas-pump" or vacuum process. The natural gas gasoline industry was confined to eight States in both 1911 and 1912; West Virginia takes first place in the quantity produced. The total production of gasoline from gas in 1912 was 12,081,179 gallons, valued at $1,157,476, as compared with 7,425,839 gallons, valued at $531,704, in 1911. The estimated quantity of gas used in the extraction of 12,081,179 gallons of gasoline in 1912 was 4,687,796,329 cubic feet, an average yield of 2·6 gallons of gasoline per thousand cubic feet of gas used. Various uses are made of the residue or "exhaust" gas, which is the gas left after the gasoline has been extracted. In some places it is sold to gas companies and run through their lines to consumers; in other places it is used to drive gas engines and the gasoline plant of the operator; but it is most commonly returned to the original producer for field purposes. In some few places it is wasted.

Alkali fusions. [Formation of acetic acid and ethane from acetylene.] Feuchter. *See* IV.

Direct recovery of ammonia as sulphate without distillation. Strommenger. *See* VII.

Determination of carbon monoxide by means of yellow mercuric oxide. Moser and Schmid. *See* XXIII.

Patents.

Coal and other slimes and materials of a like nature; Method of and apparatus for draining and concentrating ——. S. Hunter and Simon-Carves Bye-Product Coke Oven Construction and Working Co., Manchester. Eng. Pat. 22,189, Oct. 2, 1913.

The washed material is passed over an inclined sieve and the slimes which pass through the sieve are collected in a settling tank. The concentrated slimes from the tank are passed over a fine inclined sieve and from the upper surface of this sieve to a rocking sieve. The fine material which passes through the rocking sieve is delivered upon the washed material passing down the first sieve which acts as a filter.—A. T. L.

Graphite and combustibles in general; Process and apparatus for the enrichment of ——. J. Mauduit. Fr. Pat. 463,609, Dec. 20, 1912.

Graphite etc. is purified by the volatilisation of the impurities in an electric furnace. The furnace is preferably formed from a block of graphite, the openings for charging, introduction of electrodes, and escape of volatilised bodies being sealed against ingress of air. A number of electrodes may be used, and the top of the furnace through which the electrodes pass may be partly isolated from the rest by the interposition of cooling chambers to protect the packing material round the electrodes from the effect of very high temperatures.
—H. H.

Combustible; Agglomerated —— and process for manufacture thereof. Comp. d'Agglomérés d'Anthracite Pur. Fr. Pat. 463,138, Dec. 9, 1912.

Anthracite dust is mixed with 5 to 8 per cent. of finely powdered soft coal and with an agglutinant, and moulded into blocks, which are heated to 900° or 1000° C. The agglutinant is eliminated at the high temperature, the soft coal then acting as the binding agent.—H. H.

Coke-ovens; Gas-inlet nozzles for ——. H. Gossler, Herne, Westphalia. Eng. Pat. 14,241, June 19, 1913.

The nozzle is fitted coaxially with the gas supply conduit and is so tapered towards its discharge orifice as to produce eddies which serve to prevent the deposition of tar vesicles upon its sharp edge.—J. L. F.

Coke ovens; Regenerative ——. N. Schuster, London Eng. Pat. 29,517, Dec. 22, 1913.

Coke ovens having regenerative tunnels in the base o the structure are constructed so as to secure equal heatin of the whole foundation and consequent equality c expansion and contraction therein. Two pairs of tunnel run at right angles to the coke chambers, each bein divided by transverse partitions into separate regenerativ chambers equal in number to half the number of cok chambers and also to half the number of heating chambers in the oven side walls. One half of any one heating chamber is connected by a passage with one of the regenerative chambers in one tunnel of a pair, while the other half is connected with one of the regenerative chambers in a tunnel of the other pair. The two halves of the next heating chamber communicate respectively with regenerative chambers in the other tunnels of each pair, so that uniform conditions of heating always obtain. The regenerative chambers act alternately as inlet and outlet chambers for gases in the usual manner.—H. H.

Coke ovens. C. Semmler. Fr. Pat. 463,299, Oct. 6, 1913.

The hot coke from coke ovens is cooled in chambers having double walls through which water is circulated under pressure so as to become superheated, the waste heat being thus rendered available for power or heating purposes.—H. H.

Coke oven; Recuperative ——. T. von Bauer. Ger. Pat. 267,480, Feb. 13, 1913.

The heating walls of the oven are subdivided horizontally by rows of perforated boxes filled with fragments of firebrick. Air and heating gases are supplied to passages between the rows of boxes and have to pass through the masses of granular material in the boxes, whereby intimate mixing and more complete combustion are attained. —A. S.

Coke oven. Gebr. Hinselmann. Ger. Pat. 268,327, Jan. 14, 1913.

To obtain uniform heating of coke-ovens with vertical heating flues, the flues start from different heights, or some of them are made of small cross-section up to a certain height, so that the flame opens out only in the upper part of the flue.—A. S.

Coke low in sulphur; Manufacture of ——. A. Fingerland, A. Indra, and A. Lissner. Ger. Pat. 270,573, July 7, 1913.

Coal is carbonised, or coke is heated, after addition of metals, oxides, hydroxides, or salts capable of acting catalytically in the subsequent treatment, and the hot coke is then treated, preferably in a separate apparatus, with gases or vapours, which in conjunction with the substances added previously, serve to remove sulphur. For example with iron filings as catalyst and chlorine as the gas, ferric chloride and sulphur chloride are formed, both of which are volatilised.—A. S.

Gaseous fuel; Production of ——. A. W. Southey, Mill Hill. Eng. Pat. 4006, Feb. 17, 1913.

A spray of liquid fuel is injected by a jet of gas from an internal combustion engine cylinder into a chamber to which air is admitted so that partial combustion and consequent vaporisation of the fuel takes place, ignition being effected by a sparking plug. The spray is preferably directed upwards from the surface of liquid fuel maintained at a constant level in a well at the bottom of the vaporising chamber, so that it impinges against a horizontal baffle-plate from which the excess of fuel drips back into the well, while the mixture of vapour, air, and products of combustion passes on through an annular channel surrounding the baffle into the inlet pipe of the engine. See also Eng. Pat. 27,612 of 1911: this J., 1913, 77.) —H. H.

as-producers. J. B. Jolly, Chorley, Lancs. Eng. Pat. 13,737, June 13, 1913.

N a producer of the multi-chamber, shaft, regenerative ype, suitable for the treatment of sewage coke, a secondary nd temporary pronged grate is introduced above the ain grate, to hold up the fuel bed while the latter is ithdrawn and the clinker removed.—J. L. F.

as-generators. T. de Fontaine, Hanover, Germany. Eng. Pat. 18,413, Aug. 31, 1913. Under Int. Conv., Aug. 13, 1912. Addition to Eng. Pat. 24,611, Oct. 26, 1909.

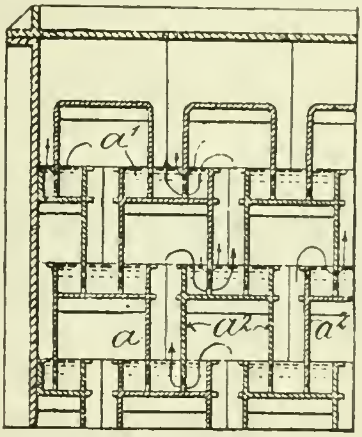
HE rotary grate generator with helical projections scribed in the chief patent (this J., 1910, 684) removes the clinker from caking coals too rapidly. To avoid this the pitch of the helical crushing surface of the breaking-jaws is gradually and continuously diminished towards their bases.—J. L. F.

Gas; Apparatus for manufacturing ——. E. C. and L. B. Jones, San Francisco, Cal. U.S. Pat. 1,089,926, March 10, 1914.

The generator comprises two lined shells, connected at the base, the shorter containing two and the longer three chambers divided by chequerwork. The lower chamber in the shorter and the middle one in the longer shell are provided with oil-inlets. The top chambers have inlets for steam and gas. The other usual inlets and outlets are provided.—J. L. F.

Washing or scrubbing gas; Apparatus for ——. P. E. Williams, Wanstead. Eng. Pat. 10,066, April 29, 1913.

The stationary washer is built up of similar units, each consisting of a chamber, *a*, open at the bottom and provided with a recessed top, a^1. The sides, a^2, stand in the corresponding recesses of the row below, and are both notched to allow free downward flow of scrubbing liquid, and perforated to permit the independent passage of ascending gas. Alternate rows are staggered to produce a cellular structure. The gas-distributing chamber units are closed and laterally flanged at each end.—J. L. F.



Purifying "producer" and like gas; Materials for ——. J. M. Wallwin, Salford, and F. S. Sinnatt, Manchester. Eng. Pat. 28,682, Dec. 12, 1913.

The purifying material is mixed with particles of cork. —J. L. F.

Blast-furnace gas; Purification of ——. W. Schwarz. Ger. Pat. 271,067, Nov. 17, 1912.

Purification is effected by a revolving washer, and the impurities, in the form of sludge, pass into an adjacent tank provided with a revolving drum, the interior of which is connected with a suction device. The impurities form a cake on the surface of the drum; this is removed by a scraper, whilst the water is returned for use again.—A. S.

Separating light oils from washing oil and regenerating the latter; Process of ——. H. Koppers, Essen-Ruhr, Germany. Eng. Pat. 15,965, July 10, 1913.

Light oils which have been separated from gas by heavier washing oils are distilled out by steam and the vapours passed through a fractionating column. The liquid condensing in the column passes into a steam-heated chamber from which a further quantity of light oil is distilled and conducted to the top of the fractionating column to mix with the other light oil vapours, while the unvaporised heavy oil passes out into cooling vessels where the naphthalene separates. The heavy oil can then be again used for washing gas.—H. H.

Carbon ; Conversion of —— into liquid hydrocarbons and halogen derivatives thereof. G. Tischenko and H. Plauson, St. Petersburg, Russia. Eng. Pat. 27,430, Nov. 28, 1912.

Coke, coal, charcoal or other carbonaceous material is impregnated with a saturated solution of the oxides, hydroxides or salts of alkali or alkaline-earth metals or of aluminium, iron, zinc, copper, lead, tin, or antimony, or the carbon is mixed with the dry salts or with the metal powder, and the mixture heated in a closed furnace by means of the electric arc in the presence of free hydrogen. water vapour, or combined water. Various hydrocarbons are formed according to the metal used, including acetylene and benzene. The gases are cooled and washed, and the hydrocarbons which have not been polymerised are passed through tubes packed with catalytic material (spongy nickel or iron) at 450°—500° C. Aluminium salts yield hydrocarbons of the methane series ; alkali carbonates yield aromatic hydrocarbons ; sodium aluminate yields a mixture of paraffins, aromatic hydrocarbons and terpenes. Halogen derivatives are obtained by using chlorides of the metals. (See also Eng. Pats. 27,428 and 27,429 of 1912 ; this J., 1914, 244.)—A. T. L.

Petroleum ; Process and apparatus for the transformation of —— and similar hydrocarbons into products having a lower boiling point. G. Renard, Brussels. Eng. Pat. 3413, Feb. 10, 1913.

A stream of liquid petroleum is forced through an uninterrupted passage, *e.g.*, a nickel steel tube 10 mm. inside and 21 mm. outside diameter, and 60 metres long, the first part of which is maintained at 400°—450° C. and at a pressure in excess of the vapour tension, such as 40 to 50 atmospheres, while the second part serves for cooling. A weighted valve at the end of the passage may be used to maintain the pressure.—H. H.

[*Mineral oil*] *Lubricant.* W. M. Simpson, Hastings. Eng. Pat. 24,461, Oct. 28, 1913.

Crude or heavy refuse mineral oil (80 to 95 per cent.) is heated to 300°—350° F. (149°—177° C.) and mixed with hot asphaltum (20 to 5 per cent.). 0·25 per cent. of graphite or mica may also be added. The lubricant is suitable for heavy machinery.—A. T. L.

Coal ; Process for converting fine —— into a marketable fuel. J. Evans, Melbourne. Eng. Pat. 18,270, Aug. 11, 1913. Under Int. Conv., Aug. 19, 1912.

See Fr. Pat. 461,400 of 1913 ; this J., 1914, 243.—T. F. B.

Gas producers. L. Carretero, Lugo, Spain. Eng. Pat. 6262, March 13, 1913. Under Int. Conv., March 14, 1912.

See Fr. Pat. 455,518 of 1913 ; this J., 1913, 936.—T. F B.

Sulphuretted hydrogen from gases ; Process for removing ——. K. Burkheiser, Hamburg, Germany. Eng. Pat. 13,724, June 13, 1913.

See Ger. Pat. 263,593 of 1912 ; this J., 1913, 971.—T. F. B.

Distilling or mixing petroleum, tar oils, etc. Ger. Pat. 270,832. *See* III.

Calorimeter for flowing liquids or gases. U.S. Pat. 1,088 280. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION ; HEATING ; LIGHTING.

Direct recovery of ammonia as sulphate without distillation. Strommenger. *See* VII.

Patents.

Distillation of bituminous matters ; Process and apparatus for the continuous fractional ——. J. G. Aarts. Fr. Pat. 463,739, July 23, 1913. Under Int. Conv., Aug. 1, 1912, July 10, 17, and 19, 1913.

Coal, etc., is supplied to a continuously acting vertical retort in such a manner that it becomes closely packed and compressed near the walls of the retort but remains loosely packed at the centre, thus allowing the distillation gases to escape readily. The coal is fed through an annular passage and is forced downwards at the sides of the retort by a spiral screw working in this passage, or by reciprocating stamps, or merely by the weight of the coal itself. The temperature increases progressively as the coal descends in the retort. The coke produced enters a cooling zone where steam is injected into the mass, and is discharged through a water-seal by a reciprocating grate or other mechanical device.—H. H.

Heating kilns and retorts ; Method of ——. D. S. Jacobus, Jersey City, Assignor to The Babcock and Wilcox Co., Bayonne, N.J. U.S. Pat. 1,086,716, Feb. 10, 1914.

In operating a series of steam heated drying kilns, saturated steam and then superheated steam are admitted to the kilns in turn. The superheated steam passes without condensation through the kiln to which it is first supplied and is then conducted into one or more of the other kilns where it condenses.—H. H.

Electric filaments ; Manufacture of ——. C. Auer von Welsbach, Vienna. U.S. Pat. 1,090,111, March 10, 1914.

A solution of a mixture of salts of osmium and of a refractory oxide is treated with a reagent such as ammonium sulphydrate which precipitates both the osmium and the refractory oxide. The precipitate is washed, dried, and heated in a reducing atmosphere till the osmium is reduced to metal, whilst the other compound remains as a refractory oxide. The resulting mixture is then formed into filaments.—W. H. C.

III.—TAR AND TAR PRODUCTS.

Tar treatment of roads. Revision of Road Board specifications. J. Gas Lighting, 1914, **125**, 807.

The chief modifications of the earlier specifications (this J., 1911, 676) are as follows : *Tar No.* 1 (*for surface tarring of roads*). The requirement that the distillate between 170° and 270° C. shall remain clear and free from crystals of naphthalene, etc., when kept at 30° C. for ½ hour, may be waived in the case of tar supplied direct from gasworks, but it is preferable not to use tar containing much naphthalene. The tar should contain from 12—21 per cent. of " free carbon " (*i.e.*, residue left after extraction with benzene and carbon bisulphide). *Tar No.* 2 (*for making tar-macadam and for surface tarring in very hot weather when the road crust is exceptionally dry*). The tar should contain 12—22 per cent. of " free carbon " and may contain up to 25 per cent. by vol. of tar (or distillates or pitch therefrom) produced in the manufacture of carburetted water-gas. *Pitch and tar oils.* Prepared pitc from tar distilleries should contain 16—28 and com mercial soft pitch 18—31 per cent. of " free carbon." Th soft pitch and tar oils may contain up to 25 per cent. o products from carburetted water-gas tar.—A. S.

Patents.

Coal tar or its products ; Treatment of —— for the remov of the properties therein tending to induce pitch cance H. W. Robinson, Sedgley. Eng. Pats. 4159 and 10,15 Feb. 18 and April 30, 1913.

The addition of small quantities of formaldehyde or oth aldehyde, or their equivalents, to coal tar at a suita stage in the distillation process, results in the producti of a pitch entirely or almost free from "auxetics" and therefore harmless as regards liability to induce pitch cancer. Should it be inconvenient to add formaldehyde during the distillation, sugar or other substance which decomposes at a temperature below 250° C., with formation of formaldehyde, may be used. When formaldehyde is to be added to the tar during distillation, it is advisable to remove the lighter fractions in the usual manner, and when the temperature of the residue reaches 250°—270° C., to introduce the formaldehyde along with the steam. Successful results have been obtained by using about 1½ gallons of 40 per cent. formaldehyde to 2000 galls. of tar. A special apparatus is described for mixing formaldehyde with the steam to be introduced into the stills. —T. F. B.

Pitch ; Hard commercial —— and method of preparing the same. C. N. Stevens, Kenilworth, Assignor to Barrett Manufacturing Co., Chicago. U.S. Pat. 1,088,635, Feb. 24, 1914.

Hard pitch in a granular and globular form is obtained by allowing the molten material, in the form of small particles, to fall through an ascending current of air into a cooling bath, and subsequently removing the product from the bath and drying it.—T. F. B.

Tar oils and tars of vegetable, animal, or mineral origin, and similar products ; Process for treating ——. R. J. Zink. Ger. Pat. 269,261, Dec. 15, 1912.

Tars or tar oils are treated with neutral or alkaline solutions of sulphonated soaps, sulphonated oils or fats, etc., such as Turkey-red oil, and the solutions or emulsions thus formed are heated or mixed with large quantities of water to separate the soluble from the insoluble fractions of the tar.—T. F. B.

Distilling or mixing petroleum, tar oils, etc. ; Process for ——. L. Steinschneider. Ger. Pat. 270,832, Jan. 7, 1913.

Steam or air is introduced intermittently under pressure into the distilling or mixing apparatus : for this purpose a series of cylinders may be provided, through which the steam or air is forced by means of pistons worked by suitable gearing : pipes with perforated distributing nozzles serve to lead the steam or air from the cylinders to suitable points in the apparatus.—T. F. B.

n-Cresol from p-cresol ; Process for separating ——. H. Terrisse. Fr. Pat. 463,221, Sept. 26, 1913.

HE mixture of *m*- and *p*-cresol is treated with the amount f 70 per cent. sulphuric acid theoretically necessary to ulphonate the *m*-cresol : this process is carried out in partial vacuum, *e.g.*, under a pressure of about 30 mm., nd preferably at a temperature of 35° to 40° C. The -cresolsulphonic acid is converted into its sodium salt y adding sodium carbonate or normal sodium sulphate nd the *p*-cresol is separated from it by distillation with eam : the residue of sodium *m*-cresolsulphonate is conerted into the free acid by treatment with sulphuric id, and the *m*-cresol is separated by means of superheated eam.—T. F. B.

on-explosive preparations [nitro-compounds] ; Process for making ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 463,288, Oct. 4, 1913. Under Int. Conv., Oct. 19 and Nov. 5, 1912, and Sept. 10, 1913.

PLOSIVE nitro-compounds, such as di- and polynitroenols and their salts, can be rendered entirely nonplosive by adding to them either waste sulphite-cellulose s, with or without addition of caustic soda or sodium rbonate, or certain inorganic salts, such as common salt, c chloride, phosphates, etc., or a phenol or salt of a enol. For example, the nitro-compound may be mixed th its own or a greater weight of sulphite lyes and the ste evaporated to dryness at a moderate temperature : product is dry and non-explosive. The addition of phenols or of the inorganic salts is especially suitable en the nitro-compounds are to be used for impregnating od.—T. F. B.

Nitrosulphazones ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 269,747, Nov. 12, 1912.

Nitrosulphazones are obtained by treating sulphazones in concentrated sulphuric acid solution with nitrating agents at low temperatures. The products can be reduced to amino-compounds, and can be combined with diazo-compounds in alkaline solution.—T. F. B.

Sulphazonesulphonic acids ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 269,748, Nov. 16, 1912.

Sulphazones can be sulphonated by treating them with sulphuric acid containing anhydride at moderate temperatures. The products are capable of combining with diazo compounds to form azo dyestuffs.—T. F. B.

Condensation products of the anthraquinone series ; Process for preparing nitrogenous ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 269,749, Jan. 26, 1913. Addition to Ger. Pat. 265,725 (see this J., 1913, 1060).

1-Amino-4-chloroanthraquinone is condensed with β-naphthol in presence of zinc chloride, at a temperature below 200° C., preferably at 180°—190° C. The product is insoluble in alcohol, acetone, and aromatic hydrocarbons, but is easily soluble in pyridine. The chlorine atom is highly reactive.—T. F. B.

Anthraquinone derivatives containing nitrogen ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 269,842, Jan. 21, 1913.

A diazonium salt of o-aminomethylanthraquinone or a derivative thereof is heated in feebly acid solution or is treated with a substance which will unite with mineral acid, or an o-aminomethylanthraquinone is treated with nitrous acid in absence of other mineral acid. The products are formed by the elimination of the elements of water or of a hydrohalogen acid from *o*-diazomethylanthraquinone or of a salt thereof, and are therefore indazole derivatives.—T. F. B.

IV.—COLOURING MATTERS AND DYES.

Iron salts of phenols. VI. Salts of alizarin ferri-acid. R. F. Weinland and K. Binder. Ber., 1914, **47**, 977—985. (See also this J., 1913, 1029.)

Alizarin forms a ferri-acid of formula :

$$[Fe(C_6H_4(CO)_2C_6H_2O_2)_3]H_3$$

which gives well crystallised sodium, potassium and ammonium salts in the form of dark reddish-black crystalline powders. These are soluble in alcohol and water ; no precipitation occurs on adding alkali to the aqueous solutions, but dilute acids destroy the colour and give a precipitate of alizarin. The calcium salt is not crystalline and is only sparingly soluble in water. A crystalline brownish-red acid potassium alizarate,

$$C_6H_4(CO)_2C_6H_2(OK)OH+C_6H_4(CO)_2C_6H_2(OH)_2,$$

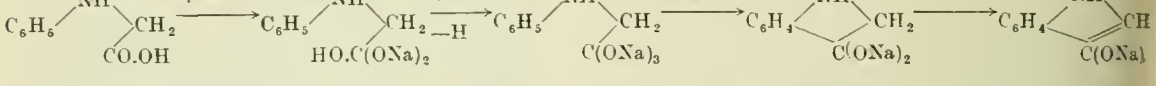
is described and also a similar tri-potassium-dializarate. —G. H. F.

Galloflavin and purpurogallin. J. Herzig. Ber., 1914, **47**, 953—955.

By the oxidation of galloflavin, or of isogalloflavin (this J., 1914, 131) with dilute nitric acid, the author obtained a crystalline substance of m. pt. 101°—103° C., proved to be oxalic acid. It was similar in properties, m. pt., and m. pt. of its dimethyl derivative, to the compound obtained by Dean and Nierenstein [Ber., 1913, **46**, 3868] by oxidising purpurogallin with dilute nitric acid and described by them as dihydroxyhemimellitic acid. Moreover, the product obtained from purpurogallin by working according to Dean and Nierenstein's method, also proved to be oxalic acid.—G. H. F.

Alkali fusions. [*Formation of indoxyl from phenylglycin and of acetic acid and ethane from acetylene.*] H. Feuchter. Chem.-Zeit., 1914, **38**, 273—274.

Theory of indoxyl ring formation in the fusion of phenylglycin with alkali. By the action of metallic sodium on anhydrous sodium acetate in presence of fused alkali at 200°—220° C., 1 mol. H_2 is evolved and 2 mols. Na consumed per 2 mols. CH_3CO_2Na, and the whole of the acetic acid of the sodium acetate can be recovered from the reaction product. This indicates that reaction takes place only at the CO-group, with formation of alkali ortho-acetate, $CH_3C(ONa)_3$, which is decomposed by water into alkali and alkali acetate. Alkali orthosulphate, $S(ONa)_6$, is formed in an analogous manner from anhydrous sodium sulphate at 260° C.: and the improved yield of alkali-indoxyl from the alkali compound of phenylglycin and fused alkali produced by addition of sodium, is attributed to an analogous formation of the ortho-salt of phenylglycin-alkali :—



Behaviour of acetylene in the alkali fusion. Acetylene is completely absorbed by fused alkali (caustic potash plus caustic soda) at 220° C., hydrogen being evolved, and the reaction product when treated with water yields alkali acetate. Alkali ortho-acetate is probably formed as intermediate product :

$$CH{\vdots}CH+2NaOH=$$

$$CH_3.CH(ONa)_2 \xrightarrow[-2H]{+NaOH} CH_3\,C(ONa)_3 \longrightarrow CH_3.CO.ONa.$$

Up to 60 per cent. of the theoretical quantity of acetic acid is produced. If metallic sodium be added to the fused alkali, acetylene is still absorbed but no hydrogen is evolved, and the residue, which is free from acetate, when treated with water evolves a volume of ethane equal to that of the acetylene absorbed.—A. S.

Bisazophenolphthalein and the coloured salts of phenolphthalein ; Constitution of ——. B. Oddo. Ber., 1914, **47**, 967—972.

EVIDENCE in support of the lactone formula,

$$(HO.C_6H_4)_2:\overline{C.C_6H_4.CO.O},$$

for phenolphthalein is given by the formation of bisazo derivatives of the type :

$$(R.N_2.C_6H_3.OH)_2:\overline{C.C_6H_4.CO.O}.$$

The latter give di-acetyl compounds, and on reduction diaminophenolphthalein, identical with the diamine formed by reducing dinitrophenolphthalein :

$$(\overset{3}{NO_2}.\overset{4}{C_6H_3}.OH)_2:\overline{C.C_6H_4.CO.O}.$$

—G. H. F.

1.2-*Naphthoquinone-4-sulphonic acid ; Condensations with* ——. F. Sachs and L. Öholm. Ber., 1914, **47**, 955—961.

OXYTHIONAPHTHENE and fluorene behave as "negative" methylene compounds (Sachs, this J., 1905, 1327), giving coloured condensation products with 1.2-naphthoquinone-4-sulphonic acid. The product from oxythionaphthene crystallises from alcohol, xylene or nitrobenzene, in fine brown-violet needles, having a metallic lustre and subliming at 170° C. It is a mordant dyestuff, and also dyes as a vat colour because of its indigoid structure, giving upon air oxidation a beautiful blue shade, very sensitive to acids.—G. H. F.

Dyestuffs ; A relation between constitution and depth of colour of ——. E. R. Watson. Chem. Soc. Trans., 1914, **105**, 759—767.

THE possession of a deep shade (*i.e.* blue, etc.) by a dyestuff is not merely a question of molecular complexity : dyestuffs which vary in shade from one end of the spectrum to the other may have similar general configurations and molecular weights, *e.g.*, hexahydroxybenzophenone and Anthracene Blue WR, diaminoazobenzene and indamine, quercetin and gallacetein, etc. The theory is put forward that if a dyestuff be quinonoid in all its possible tautomeric forms it will show a deep colour, however simple the molecule may be. If, on the other hand, there is a possibility of the molecule existing in a non-quinonoid form it will not attain a deep colour, although the molecule may be complex. Thus, the triphenylmethane dyestuffs, the pyronines, benzeins, fluorones, indophenols, indamines, oxazines, thiazines and azines all satisfy the test for a deep colour. On the other hand the benzophenone and xanthone derivatives, the flavones and flavonols, ellagic acid and the azo-dyestuffs can all be represented by non-quinonoid formulæ and many members of these groups, despite considerable molecular complexity, have no great depth of colour. To ensure a deep colour it is not sufficient that a substance should have a permanently quinonoid structure, but it must be capable of tautomerisation from one quinonoid arrangement to another, the change taking place in one and the same benzene ring. Dyes which have possible non-quinonoid forms are not included, many of these (*e.g.* indigo) having deep colours. Irregularities are introduced into the author's scheme by certain factors well known to have a deepening effect on the shape of dyestuffs, *e.g.*, increasing the number of auxochromes, the replacement of hydroxyl- by substituted amino-groups, and so on. The theory explains the contrast in shade between auramine, which can be represented in a non-quinonoid form, and the triphenylmethane dyestuffs, which are quinonoid in all their possible tautomeric forms.—J. B.

Secondary colours : Contribution to the question of ——. E. Havas. Ber., 1914, **47**, 994—995.

SPECTROSCOPICAL examination of 1-aminophenylphenazonium chloride, and of 1-aminophenylnaphthophenazonium chloride, support the view of Kehrmann and Cordon (this J., 1913, 973) that the greenish yellow colour of thes compounds is to be regarded as secondary yellow.—G. H. I

PATENTS.

Azo dyestuffs ; Manufacture of yellow ——. P. A. Newto London. From Farbenfabr. vorm. F. Bayer und C Elberfeld, Germany. Eng. Pat. 8415, April 9, 1913.

THE diazo compounds of toluidines or their sulphon acids are combined with 1-chlorophenyl-3-methylpyrazolonesulphonic acids, or the diazo compounds a combined with acetoacetic ester and the resulting co pounds are condensed with chlorophenylhydrazines phonic acids. The products dye wool from acid bat level greenish-yellow shades, fast to light.—T. F. B.

Monoazo dyestuffs ; Process for producing ——. Farb fabr. vorm. F. Bayer und Co. First Addition, dat Oct. 2, 1913, to Fr. Pat. 457,840, April 21, 1913. Un Int. Conv., Oct. 15, 1912.

DYESTUFFS analogous to those described in the princi patent (see this J., 1913, 1004) are obtained by combin with naphtholsulphonic acids, aminonaphtholsulpho acids, etc., the diazo compounds of the aminobenzin azole or *p*-aminophenylazimino derivatives of amisalicylic acid. The benziminazole derivatives may be obtained by condensing aminosalicylic acid with dinitrochlorobenzene, reducing, and treating the resulting 2.4-diaminophenylaminosalicylic acids with acidylating and saponifying agents. The aminophenylazimino compounds may be obtained by reducing 2.4-dinitrophenyl-*p*-aminosulphosalicylic acid to the nitro-amino compound, treating with nitrous acid, and reducing the product. The resulting dyestuffs furnish fast shades varying from yellowish-red to bluish-red and red-violet.—T. F. B.

Vat dyestuffs of the anthraquinone series containing sulphur ; Process for producing ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 463,698, Oct. 16, 1913. Under Int. Conv., Oct. 25, 1912.

SUBSTANCES which dye cotton yellow to red shades from the vat, are obtained by the action of a polythiophenol on at least two mols. of a negatively-substituted anthraquinone derivative, or by the action of a derivative of benzene containing two or more halogen atoms on at least two mols. of an anthraquinonyl-mercaptan. The dyestuff from α-chloroanthraquinone and benzene-1.3-dimercaptan gives yellow shades from the vat, whilst that from 1-benzoylamino-4-chloroanthraquinone and benzene-1.3-dimercaptan dyes scarlet shades.—T. F. B.

Vat dyestuffs of the anthraquinone series ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 270,579, Aug. 13, 1912.

AMINOANTHRAQUINONES or their derivatives are treated with oxalic esters in presence of alkaline condensing agents. The products dissolve with difficulty, and may be used as vat dyestuffs.—T. F. B.

Pyridone dyestuffs ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 269,894, Jan. 4, 1913.

α-PYRIDONES are condensed with secondary or tertiary aromatic amines in presence of dehydrating condensing agents. The resulting dyestuffs can be applied to wool and to tannin-mordanted cotton. Orange-red shades are obtained with the products from the simplest pyridones and from the quinolones, whilst blue dyeings are produced with those from the anthrapyridones.—T. F. B.

Polyazo dyestuffs ; Manufacture of ——. R. B. Ransford, London. From L. Cassella und Co., G. m. b. H., Frankfort, Germany. Eng. Pat. 8984, April 16, 1913.

A *p*-NITROAMINE is diazotised and combined with a naphtholsulphonic acid, the monoazo dyestuff is reduced, diazotised, and combined with 1.6- or 1.7-naphthylaminesulphonic acid, and the product is diazotised and combined with resorcinol : the same result is obtained by saponifying the monoazo dyestuff from an acetyl-*p*-diamine and a naphtholsulphonic acid and then proceeding as above. Identical dyestuffs are obtained by combining diazotised 4-nitro-1-naphthylamine-6- or -7-sulphonic acid or 4-acidylamino-1-naphthylamine-6- or -7-sulphonic acid with an amine having a free *p*-position, diazotising, combining with a naphtholsulphonic acid, reducing or saponifying, again diazotising, and finally combining with resorcinol. Another method for preparing the dyestuffs is to diazotise a monoazo dyestuff of the type, $NH_2.X.N_2$-Clève's acid, combine with a naphtholsulphonic acid, diazotise, and finally combine with resorcinol. The products dye cotton fine greenish to reddish blue shades, fast to washing and to light : the fastness to washing may be improved by after-treatment with formaldehyde.
—T. F. B.

Basic dyestuffs ; Process for preparing ——. L. Cassella und Co. Ger. Pat. 269,802, Jan. 8, 1913.

AMINOACRIDINIUM dyestuffs are treated with aqueous solutions of metallic cyanides, and the products are oxidised. The intermediate compounds possess no tinctorial properties, but oxidation converts them into basic dyestuffs which dye red to violet shades.—T. F. B.

Vat [anthracene] dyestuffs and process for their formation. M. Iljinsky, and R. Wedekind und Co., Uerdingen on Rhine, Germany. Eng. Pat. 19,435, Aug. 27, 1913.

DYESTUFFS containing sulphur, which produce olive and brown shades from the hydrosulphite vat, are obtained by heating with thiosulphates in absence of any solvent or liquid diluent, anthraquinonesulphonic acids or their salts, alizarinsulphonic acids or their salts, sulphonic acids of anthraflavic acid or of *iso*-anthraflavic acid or their salts, or their halogen derivatives, or 2-hydroxyanthraquinone or its 1-chloro- or dibromo-derivatives. All the products are insoluble in sodium sulphide solutions. The dyestuffs obtained by this process from 2-hydroxyanthraquinone, 1-chloro-2-hydroxyanthraquinone, or dibromo-2-hydroxyanthraquinone may be dissolved in concentrated sulphuric acid, precipitated by adding water, and treated with an alkaline solution of chlorine ; this treatment converts the brown dyestuffs into orange-red dyestuffs of very pure shade.—T. F. B.

Polyazo colouring matters ; Process for the manufacture of bronze-brown to olive-brown direct dyeing ——. Chem. Fabrik vorm. Sandoz, Basle. Eng. Pat. 23,119, Oct. 13, 1913. Under Int. Conv., Feb. 12, 1913.

A TETRAZOTISED *p*-diamine of the diphenyl series is combined with one mol. of a phenol-*o*-carboxylic acid and with one mol. of 1.8-aminonaphthol-3.6-disulphonic acid, and the amino group is diazotised and combined with resorcinol ; if this trisazo dyestuff is combined with a nitro-diazo compound of the benzene series in feebly alkaline solutions or in solutions made feebly acid with a fatty acid, polyazo dyestuffs are obtained, which are readily soluble in water and dye unmordanted cotton from neutral or feebly alkaline baths, bronze-brown to olive-brown shades fast to washing. Subsequent treatment of the dyeings with chromium fluoride or with bichromate and acetic acid increases their fastness to washing without appreciably altering the shade.—T. F. B.

Safranine dyestuffs ; Derivatives of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 463,357, Oct. 7, 1913. Under Int. Conv., July 15, 1913.

NEW derivatives of dyestuffs of the Safranine series, which are insoluble or very sparingly soluble in water, can be obtained by treating the dyestuffs or their salts with tannin. The products are especially suitable for use in making colour lakes. *Example :* 1000 parts of Tolusafranine hydrochloride are dissolved in hot water and 500 parts of sodium acetate and then an aqueous solution of 2000 parts of tannin are added. The tannin derivative separates and is filtered, washed with cold water, and dried.—T. F. B.

Condensation products [dyestuffs] from carbazoles and phthalic anhydride. Badische Anilin und Soda Fabrik. Fr. Pat. 463,508, Oct. 10, 1913. Under Int. Conv., Nov. 1, 1912.

CARBAZOLE or one of its derivatives is condensed with phthalic anhydride in presence of concentrated or slightly diluted sulphuric acid. The products which do not contain sulphonic groups are vat dyestuffs, whilst the sulphonated products are direct wool dyestuffs. They are formed by the condensation of one or two mols. of phthalic anhydride with each carbazole nucleus, and are probably anthraquinone derivatives. The products may with advantage be treated with a hypochlorite. The sulphonated product from carbazole and phthalic anhydride, when so treated, dyes wool golden yellow shades fast to washing. The phthalic anhydride may be replaced by its substitution products, such as the chloro derivatives. The new products are different from those formed when condensation is effected in presence of aluminium chloride and the products treated subsequently with sulphuric acid.—T. F. B.

Acridones and thioxanthones of the benzanthrone series ; Process for preparing ——. Badische Anilin und Soda Fabrik. Ger. Pat. 269,850, Sept. 21, 1912.

THE products obtained by condensing aromatic amino- or mercapto-compounds with halogenbenzanthronecarboxylic acids, in which the halogen and carboxyl groups are adjacent, are treated with condensing agents in such a manner that the acridone or thioxanthone ring is formed. The products dye indigo-blue to green shades from the vat.—T. F. B.

Indigoid dyestuffs; Process for preparing ——. Kalle und Co., A.-G. Fr. Pat. 463,772, Oct. 4, 1913. Under Int. Conv., Nov. 14 and 19, 1912, and Feb. 15, 1913.

See Ger. Pat. 269,123 of 1912; this J., 1914, 247. The pheno-hydroxynaphthocarbazoles derived from α- or β-naphthylamine may also be condensed with homologues or substitution products (in the position 2) of 2.3-diketodihydro-(1)-thionaphthene and the products treated with halogens. The condensation product from 2.1-pheno-5-hydroxynaphthocarbazole and 2-dibromo-3-ketodihydro-(1)-thionaphthene after bromination dyes cotton violet-blue shades from the vat. Again, products which dye deep blue or green to black shades from the vat, are obtained by condensing α-isatin derivatives with derivatives of naphthols such as arylamino, aryltriazole, aryltriazine, aryliminazole, or arylthiazole derivatives: the tinctorial properties of these products are improved by halogenation. Further, vat dyestuffs which furnish deep blue to black shades are obtained by condensing α-derivatives of isatin with the acidyl derivatives or the ureas of heteronuclear aminonaphthols or their homologues or substitution products; for example, the product obtained by condensing 2-benzoylamino-5-naphthol with isatin-α-anilide in presence of acetic anhydride, dyes textile fibres fast black shades from the vat.—T. F. B.

Monoazo dyestuffs for wool; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 269,799, Oct. 13, 1912.

The diazo compound of an aminodiarylsulphone, aminodiarylsulphoxide, or aminodiarylsulphide is combined with an alkylbenzylanilinesulphonic acid. The products dye wool level yellow to orange-red shades, which are faster to washing and fulling than other known dyestuffs derived from alkylbenzylanilinesulphonic acids.—T. F. B.

Monoazo dyestuffs for wool; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,942, Dec. 7, 1912. Addition to Ger. Pat. 269,799.

The acids obtained by sulphonating dibenzylaniline and benzyl-o-toluidine are used in place of the alkylbenzylanilinesulphonic acid mentioned in the principal patent (see preceding abstract). The products dye wool fast yellow to orange shades. When sulphuric acid monohydrate at 100° C. is used for the sulphonation of the above amines, the products are dibenzylanilinedisulphonic acid and benzyl-o-toluidinemonosulphonic acid.—T. F. B.

Vat dyestuffs of the anthraquinone series; Process for preparing ——. A. Schaarschmidt. Ger. Pat. 269,800, Oct. 5, 1912.

The o-cyanimines or o-cyanothioethers, obtained by condensation of o-halogen-nitriles of anthraquinone or its derivatives with amino- or thio-anthraquinones, are treated with condensing agents. The products, which are vat dyestuffs, consist of dianthraquinonylacridones and dianthraquinonylthioxanthones, respectively.—T. F. B.

2-Thionaphthene-2-indole-indigo or its derivatives; Preparation of transformation products of ——. Ges. f. Chemische Industrie in Basel. Ger. Pat. 270,334, April 6, 1913.

2-Thionaphthene-2-indole-indigo or one of its derivatives is treated with benzoyl chloride or an analogous substance, preferably in presence of a diluent or a condensing agent. Red or violet products are obtained, which have the properties of vat dyestuffs.—T. F. B.

Azo dyestuffs; Process for preparing ——. Anilinfarben und Extrakt-Fabrik vorm. J. R. Geigy. Ger. Pat. 270,831, Dec. 14, 1912. Addition to Ger. Pat. 261,047 (see Fr. Pat. 450,866 of 1913; this J., 1913, 593).

Azo dyestuffs derived from diazophenols or their derivatives are treated in alkaline solution or suspension with an arylsulphochloride. The products are suitable for use in dyeing silk and wool and in preparing lakes.—T. F. B.

Colouring agents and processes for their production. R. Vidal, Asnières, France. Eng. Pat. 17,982, Aug. 7, 1913.

See Fr. Pat. 458,545 of 1912; this J., 1913, 1061.—T. F. B.

Vat dyestuffs; Manufacture of ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 22,528, Oct. 6, 1913. Addition to Eng. Pat. 19,599, Aug. 27, 1912.

See Addition of Sept. 24, 1913, to Fr. Pat. 447,592 of 1912; this J., 1914, 247.—T. F. B.

Anthracene dyes and process of making same. O. Bally, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,086,123, Feb. 3, 1914.

See Fr. Pat. 408,787 of 1909; this J., 1910, 621.—T. F. B.

Anthraquinone vat dyes. M. H. Isler, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,090,621, March 17, 1914.

See Eng. Pat. 21,615 of 1912; this J., 1913, 694.—T. F. B.

Vat [anthracene] dye; Brown ——. A. Lüttringhaus, Mannheim, O. Lohse, and A. Sapper, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,090,636, March 17, 1914.

See Eng. Pat. 28,361 of 1912; this J., 1913, 1004.—T. F. B.

Cotton [azo] dyes. A. Blank, C. Heidenreich, and J. Jansen, Leverkusen, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,090,379, March 17, 1914.

See Eng. Pat. 8767 of 1913; this J., 1913, 905.—T. F. B.

Disazo dyestuff. A. L. Laska and A. Zitscher, Offenbach, Assignors to Chem. Fabr. Griesheim-Elektron, Frankfort on Maine, Germany. U.S. Pat. 1,091,148, March 24, 1914.

See Fr. Pat. 461,644 of 1913; this J. 1914, 195.—T. F. B.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Artificial silk manufacturing results. Chem. Trade J., April 4, 1914. [T.R.]

The viscose process for the manufacture of artificial silk is making rapid progress among Continental manufacturers, and the financial results of two important concern that have discarded other processes in favour of th viscose process is sufficient to show that the change ha not been made at the expense of the profits. The Fabriqu de Soie Artificielle de Tubize, which has hitherto manu factured by the guncotton process, is increasing its capita by two million francs in order to acquire a controllin interest in a new company which will work the viscos system in Belgium. The last report shows a net profi of 1,088,902 francs, and dividends of 25 per cent. on th preference shares and 20 per cent. on the ordinary shar are being paid. The report issued by the Vereinigt Glanzstoff-Fabriken, Elberfeld, probably the largest pr ducers of artificial silk in the world, shows a net profit

5,743,598 marks, against 3,726,825 marks in the previous year, and a dividend of 34 per cent. is proposed. Up to about two years ago this company worked only the cuprammonium process, but it has since adopted the viscose one, with good results.

Patents.

Medicated fibrous substances. P. H. Head, Horley, Surrey. Eng. Pat. 7650, April 1, 1913.

Wool or other animal fibre is scoured, carded into the state of a flat band resembling wadding, and impregnated with capsicum or capsicin, or other drugs of a stimulating nature such as iodine, iodoform, eucalyptus or terebene. —J. B.

Plastic composition, its manufacture and industrial application; A new ——. Y. Charuel. Fr. Pat. 463,156, Oct. 2, 1913.

The composition contains 4—25 per cent. of cellulose acetate, 60—95 of acetone and 1·5—5 per cent. of refined paper pulp, which may be either moist or dry. It is suitable for packing joints, insulating cables or the manufacture of plates, discs, etc. Neutral bodies, such as resin, shellac, asbestos, etc., may be incorporated for special purposes.—J. F. B.

Artificial silk; Process for increasing the flexibility and strength of articles composed of ——. J. A. E. Friedel. Fr. Pat. 463,160, Oct. 2, 1913. Under Int. Conv., July 31, 1913.

Articles of artificial silk, *e.g.*, stockings, are rendered supple by stretching them upon a block, immersing in water, or steam, not too hot, and then rapidly drying. —J. F. B.

Textile articles from solutions of cellulose or plastic masses; Process and apparatus for producing ——. B. Borzykowski. Fr. Pat. 463,400, Oct. 8, 1913. Under Int. Conv., Oct. 9, 1912.

A thin layer of a solution of cellulose or other plastic composition is discharged from the orifice of a spreading machine upon a smooth surface and is then impressed by an engraved roller, situated in front of the spreading machine, with designs representing a woven fabric or other tissue. A mass composed of cellulose beaten up with caustic soda with the addition of starch and gluten may also be employed; decorative substances and metallic powders may be incorporated with the mass. The depressions on the engraved roll may contain coagulating liquids or other substances. The tissue is neutralised, fixed and purified in subsequent baths.—J. F. B.

Viscose and similar products; Process of rendering impermeable, articles made from ——. P. Lagrange. Fr. Pat. 463,613, Dec. 21, 1912.

Articles of cellulose manufactured from viscose or uprammonium solution, *e.g.*, artificial flowers, leaves, etc., re rendered impermeable by a thin coating of an ester of ellulose.—J. F. B.

ellulose products [*viscose*]*; Manufacture and strengthening of* ——. A. Chesnais. Fr. Pat. 463,693, Dec. 23, 1912.

N the manufacture of cellulose products from the xanthate uitable derivatives of phosphorus, particularly hypohosphorous acid, are employed to dehydrate the cellulose olecule. The hypophosphorous acid may be added to he viscose itself or may be used in the coagulating or xing baths or may be applied to the already fixed roducts.—J. F. B.

elluloid substitute and process of manufacturing same. A. S. von Szolayski. Fr. Pat. 463,906, Oct. 22, 1913.

solution of 3 parts by vol. of gelatin in cold water is corporated with a mixture of 3 parts by vol. of casein d 3 parts of sodium silicate and the whole is hardened alum or equivalent tanning substance.—J. F. B.

Sulphite pulp from resinous woods; Manufacture of ——. O. Carr, Asheville, N.C. U.S. Pat. 1,089,691, March 10, 1914.

Before digesting with sulphite the chips are extracted with turpentine and with an alkaline solvent to remove resinous substances.—J. B.

Paper pulp; Apparatus for straining ——. W. W Beaumont. Fr. Pat. 463,392, Oct. 8, 1913. Under Int. Conv., Oct. 10, 1912.

In a drum strainer, the drum is oscillated silently at a high speed in a circular or elliptical path by means of vibro-motors operating through arms on which the drum is suspended. Silence is obtained by means of springs which take up the reciprocating motion of the articulated joints. Means are provided for rotating the drum simultaneously about its axis, also for regulating the amplitude and varying the path of the oscillatory motion of the arms.—J. F. B.

Paraffined paper, pasteboard, etc.; Process for preparing ——. A. Lutz. Ger. Pat. 269,963, March 29, 1912.

An aqueous emulsion of paraffin is applied to the paper on the machine during the manufacturing or finishing process. In particular, it may be added to the water used for moistening the web.—T. F. B.

Ethers of cellulose, its conversion products and derivatives; Process for the manufacture of ——. L. Lilienfeld, Vienna. Eng. Pat. 6035, March 11, 1913. Under Int. Conv., March 16, 1912.

See Fr. Pat. 447,974 of 1912; this J., 1913, 420.—T. F. B.

Plastic and elastic compositions, artificial filaments, films, coatings, and the like products [*from cellulose ethers*]*; Manufacture of* ——. L. Lilienfeld, Vienna. Eng. Pat. 6387, March 14, 1913. Under Int. Conv., March 16, 1912.

See Fr. Pat. 459,972 of 1913; this J. 1913, 1153.—T. F. B.

Films; Apparatus for the production of ——. B. Borzykowski, Berlin. U.S. Pat. 1,090,649, March 17, 1914.

See Fr. Pat. 454,692 of 1913; this J., 1913, 865.—T. F. B.

[*Paper*] *pulp; Preparing* ——. C. Bache-Wüg, Portland, Maine, U.S.A. Eng. Pat. 944, Jan. 13, 1914.

See U.S. Pat. 1,084,244 of 1914; this J., 1914, 196.—T.F.B.

Extracting resinous and other products from wood, with simultaneous production of paper pulp Fr. Pat. 463,879. *See* XIII.

Imitation rubber with a basis of acetylcellulose. Fr Pat. 463,622. *See* XIV.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Glycollic acid and its application [*in dyeing and printing*]. O. Diehl. Färber-Zeit., 1914, 25, 138—141.

Glycollic acid, prepared electrolytically from oxalic acid, is now available for industrial purposes. Its properties are comparable with those of tartaric acid, over which it is stated to have many advantages for use in dyeing and printing. For example, it has a highly solvent action on the tannin lakes of basic dyestuffs and can be advantageously used in the printing of such colours on cloth prepared with β-naphthol. Patterns are given illustrating its use in this way for New Methylene Blue and Para Red effects. In wool printing the use of glycollic acid is said to decrease the marking off which is a defect of the Ponceaux and Bordeaux. In wool printing also the use of ammonium glycollate is recommended instead of ammonium oxalate. Aluminium and tin glycollates are stated to give good results in Alizarin and Alizarin Orange printing, and in printing with chromium acetate the addition of glycollic acid is said to preserve the colour without interfering with lake formation on steaming. The replacement of part of the hydrochloric acid in Aniline Black dyeing by glycollic acid reduces the risk of tendering.—J. B.

Patents.

Bleaching textiles by stearine emulsions. E. Lasbordes. Third Addition, dated Sept. 25, 1913, to Fr. Pat. 399,514, Feb. 8, 1909.

A violet (preferably acid) dyestuff, capable of resisting the action of sulphurous acid, is added to the bleaching agent described in the chief patent and previous additions thereto, and also in Fr. Pat. 400,792 (this J., 1909, 979, 1094, 1122; 1911, 1052).—J. B.

Mercerising; Process for purifying caustic soda solutions used in ——. E. V. Chambers and T. C. Hammond, Huddersfield. Eng. Pat. 3063, Sept. 6, 1913.

Mercerising liquor which has become too impure for further use is carbonated by means of flue gases which have been washed free from acids and dust. The organic impurities are thereby precipitated and after the separation of these the sodium bicarbonate solution is re-causticised by means of lime. Alternatively the carbonation may be carried only to the normal carbonate stage and pure sodium carbonate obtained by crystallisation.—J. B.

Silk weighting with haematoxylin; Process of ——. F. Müller, Zürich, Switzerland. Eng. Pat. 26,735, Nov. 20, 1913. Under Int. Conv., April 5, 1913.

A water-soluble phosphate is added directly to the hæmatoxylin bath, with or without the addition of soap, whereby an increased weighting is obtained; for example, scoured silk, previously weighted as usual with zinc hydroxide, phosphate or phosphate-silicate, is treated with 100 per cent. of hæmatoxylin and 50 per cent. or more of sodium phosphate, the temperature being gradually raised from 50° C. until the required weight is attained.—J. B.

Aniline Black; Process for dyeing ——. A. E. Vergé, Vincennes, France. Eng. Pat. 15,668, July 7, 1913.

The process differs from the known air-oxidation method in the use of a greater proportion of aniline and *p*-phenylenediamine and a smaller proportion of copper salt and metabisulphite, and in the omission of ammonium chloride. After partial drying and a cold air ageing, the goods are "finished" by impregnating in a chromate bath containing about ½ per cent. of aniline and passed over drying cylinders, or the chromate bath itself is heated. The aniline may, alternatively, be applied separately before chroming. (Reference is directed to Eng. Pat. 16,189 of 1907; this J., 1908, 854.)—J. B.

Aniline Black on cotton; Process for producing —— *by the cold process.* K. Biltz. Ger. Pats. 270,059 and 270,060, Nov. 19, 1912, and April 1, 1913.

(1) Cotton is immersed for one hour in a bath containing aniline salt, sodium chlorate, ammonium chloride, copper sulphate, and aluminium acetate, together with an amount of oxalic acid corresponding to 1 to 2 per cent. of the weight of the goods to be dyed; the impregnated fibre is freed from excess of liquid, and then immersed, without drying, for three hours in a bath containing aniline salt, sodium bichromate, and sulphuric acid, together with oxalic acid (5 per cent. of the weight of the cotton). The goods are finally treated with a solution of ferrous-ammonium sulphate, sodium bichromate, copper sulphate, and sulphuric acid. The dyeings are very fast to fulling, and compare favourably with those produced by the usual methods as regards fastness to light, acid, and alkali; they do not bleed on white goods. (2) The second and third baths may be combined, with the result that the entire process only occupies from three to four hours.—T. F. B.

Dyeing and otherwise treating cloth with liquids; Machine for ——. A. J. and J. A. Rau. Fr. Pat. 463,603, Oct. 14, 1913. Under Int. Conv., Oct. 17, 1912.

The machine is a form of jigger, in which the cloth passes through the bath along with an endless apron of woven wire revolving under tension between two rollers, one vertically above the other. A casing encloses the apron, and the dye-liquor is caused to circulate from the outside, through the casing (which is constructed of filtering material) thence through the moving cloth and into the interior of the apron, whence it is returned to the circulating apparatus.—J. B.

Machine for dyeing cotton and linen with vat or sulphide dyestuffs. P. Kaufmann. Fr. Pat. 463,779, Oct. 18, 1913.

The cloth is passed from the preparing bath over a stretcher and into the dyebath, through which it passes along with an endless apron. The dyebath is made deep (2 to 3 metres) and narrow (1 to 1·20 metres) and has a curved bottom on which the cloth is fed in pleats by a pair of rollers fitted to with a scraper to prevent entanglement.—J. B.

Discharging vat and sulphide colours with reducing agents; Process for ——. R. B. Ransford, London. From L. Cassella und Co., Frankfort-on-Maine, Germany. Eng. Pat. 17,031, July 24, 1913.

In cases where a satisfactory white cannot be obtained in discharging vat and sulphide dyestuffs (*e.g.*, Hydron Blue R, Tetrabromoindigo, etc.) with reducing agents (*e.g.*, Hydraldite CL combined with Leukotrope W), the cloth is padded with a solution of an alkali such as caustic soda, sodium carbonate, borax or sodium silicate, then dried and printed with the discharge.—J. B.

Discharges on indigo and other reducible dyestuffs; Process for producing coloured —— *by means of vat dyestuffs.* Gebr. Enderlin, Druckfabr. u. Mechanische Weberei A.-G. Ger. Pat. 270,124, Aug. 26, 1913. Addition to Ger. Pat. 263,647.

The discharge colours mentioned in the principal patent (see this J., 1913, 1007) are replaced by mixtures containing the vat dyestuff and the discharging agent (*e.g.*, Rongalite CL), together with anthraquinone and zinc oxide; the iron and tin salts are omitted.—T. F. B.

Reserving gallocyanine dyestuffs and their leuco compounds on cotton fibre; Process for ——. Farbwerke vorm. L. Durand, Huguenin und Co. Ger. Pat. 269,933, May 3, 1913.

The fibre is printed with a reserve paste containing chromium phosphate and the chromium salt of a hydroxycarboxylic acid of the aliphatic series, before the application of the dyestuff. Pure white reserves are obtained, even with dark shades.—T. F. B.

Lustre resistant to water and soap; Process for giving cotton goods a silky ——. C. Rumpf. Fr. Pat. 464,114 Oct. 25, 1913. Under Int. Conv., Oct. 28 and Nov. 16 1912.

The goods are moistened with an oxidising agent (*e.g.*, solution of 100 to 250 grms. of potassium bichromate i 100 litres of water, or a solution of 5 to 35 parts of 10 pe cent. by vol. hydrogen peroxide in 100 parts of water) an then hot calendered with pressure. Or, the goods may b treated with the oxidising agent and then dyed an finally calendered; for example, goods are boiled for 45 t 60 mins. in a solution of 15 to 70 parts of hydroge peroxide (10 per cent. by vol.) in 100 parts of water, t which a little ammonia is added, and finally washed, drie moistened and calendered.—J. B.

Dyeing machines. W. Schlbach, Barmen, Germany. Eng. Pat. 13,947, June 16, 1913. Under Int. Conv., June 14, 1912.

See Fr. Pat. 459,196 of 1913; this J., 1913, 1106.—T. F. B.

Dyeing vegetable fibres. J. Turner and H. Dean, Assignors to Read Holliday and Sons, Ltd., Huddersfield. U.S. Pat. 1,090,176, March 17, 1914.

See Fr. Pat. 455,803 of 1913; this J., 1913, 940.—T. F. B.

Dyeing and washing machine. W. Higgins and J. Rhodes, Bradford. U.S. Pat. 1,090,397, March 17, 1914.

See Eng. Pat. 14,190 of 1911; this J., 1912, 638.—T. F. B.

Fabrics; Apparatus for drying —— A. T. Metcalf and H. V. Nunn, Assignors to Bradford Dyers' Assoc., Ltd., Bradford. U.S. Pat. 1,090,934, March 24, 1914.

See Eng. Pat. 8756 of 1911; this J., 1912, 122.—T. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Boric acids; Complex ——. N. Dhar. Z. anorg. Chem., 1914, **86**, 196—200.

The effect of the added glycerol or mannitol in the titration of boric acid is probably to form a complex anion which can unite with the hydrogen ion to give an acid much stronger than boric acid. The salts of the new acid are not hydrolysed to such an extent as the borates so that it is possible to titrate it with alkali in the presence of phenolphthalein. If this view is correct the conductivity of boric acid solution should be greatly increased by adding glycerol or mannitol. This is actually the case and, as would be expected from the law of mass action the increase of conductivity is proportional to the concentration of boric acid and of the hydroxy compound in the solution. —W. H. P.

Ammonia; Direct recovery of —— as sulphate, without distillation. W. Strommenger. Stahl u. Eisen, 1913, **41**, 1694—1697.

For removing tar from hot gases previous to the direct recovery of ammonia as sulphate, the author describes a scrubber composed of two superposed chambers containing washing-tar up to the level of an overflow. The gases, brought to the desired temperature by means of a spray of ammonia liquor, are admitted to a number of inverted troughs immersed in the tar, and having serrated lower edges; two perforated plates are also immersed in the tar in order to ensure intimate contact between the gases and the tar. The gases pass first through the lower and then through the upper chamber, and in the latter there s a filter above the tar level, to retain any tar spray. The washing tar is renewed by the tar separated from the gas, and the surplus runs continuously from the overflows. The apparatus has been in use for some time in connection with 120 coke ovens at Ruhrort. No tar could be detected n the gases leaving the scrubber, and the quantity of ammonia in the gases leaving the saturator was only 0·75 grm. per 100 cb. m. The sulphate of ammonia was of a good grey colour, and contained 25 per cent. NH_3 on leaving the hydroextractor.—A. T. L.

Potassium tetroxide. R. de Forcrand. Comptes rend., 1914, **158**, 843—846.

Potassium tetroxide was decomposed with sulphuric acid, and its heat of formation calculated to be: K_2 sol. + O_4 gas = K_2O_4 sol. + 133·74 cals.; K_2O sol. + O_3 gas = K_2O_4 sol. + 46·94 cals. The heat of formation of sodium tetroxide from the monoxide would probably only be about 29 cals., of which 19 cals. are liberated for the change $Na_2O \rightarrow Na_2O_2$, so that trioxide and tetroxide of sodium must be very unstable substances.—G. F. M.

Barium chloride solutions; Electrolysis of —— with mercury cathodes. P. P. Fedotieff. Z. anorg. Chem., 1914, **86**, 325—337.

The Kellner-Solvay method may be applied with good results to the preparation of pure baryta from barium chloride solution, a given current yield being obtained with smaller cathode density than with the alkali chlorides, owing to the relative stability of barium amalgam. The amalgam is, however, rapidly decomposed by water at 60° C. in the presence of iron, and a solution which, on cooling, deposits crystals of $Ba(OH)_2$, $8H_2O$, is readily prepared. Castner's method is less suitable. An increased cathode density is favourable to a high current yield. —F. Sodn.

Nitrates of potassium, barium, and strontium; Solubility of —— and the stability of the double nitrate of potassium and barium. A. Findlay, I. Morgan and I. P. Morris. Chem. Soc. Trans., 1914, **105**, 779—782.

The results of experiments on the solubility of barium nitrate in the presence of potassium nitrate at 9·1°, 21·1°, and 35° C. are given in a table and a curve-diagram. The double salt, $2KNO_3,Ba(NO_3)_2$, has a wide range of stability which increases as the temperature rises. The positions of the curves show that at the temperatures mentioned and at higher temperatures, the double salt could be crystallised only from solutions containing excess of potassium nitrate, whilst on recrystallisation from water it would deposit barium nitrate first and leave a solution relatively rich in potassium nitrate. Using strontium nitrate instead of barium nitrate no double salt was observed at 20° or 40° C. The only solid phases at 20° were KNO_3 and $Sr(NO_3)_2,4H_2O$ and at 40° C. KNO_3 and $Sr(NO_3)_2$.—W. H. P.

Nitrates; Reaction of —— with formic acid and their determination. U. Molinari. Staz. sperim. agrar. ital., 1913, **47**, 24—32. Chem. Zentr., 1914, **1**, 1221—1222.

Experiments with potassium and barium nitrates and formic acid of different concentrations showed that the method proposed by Quartaroli (this J., 1911, 926) for the determination of nitrates is useless, the gases produced containing varying quantities of nitrous and nitric oxides and carbon dioxide under practically constant experimental conditions.—A. S.

Nitrites; Investigations on ——. M. Oswald. Ann. Chim. Phys., 1914, [9], **1**, 32—112. Chem. Zentr., 1914, **1**, 1151—1154. (See also this J., 1911, 359; 1913, 83.)

The only practical method for the preparation of pure nitrites is by fractional crystallisation of commercial sodium nitrite; silver nitrite is prepared from the purified sodium nitrite and then serves for the preparation of other nitrites by double decomposition. The solubility of potassium and sodium nitrites at different temperatures is as follows:—

Parts of nitrite dissolved by 100 parts of water at:—

	0° C.	10° C.	20° C.	30° C.	40° C.	50° C.	60° C.	70° C.	80° C.	90° C.	100° C.	110° C.	120° C.	130° C.
NO_2 ……	281	291	302	313	325	337·5	351	365	380	396	413	432	451	473
aNO_2 ……	73	78	84	91·5	98·5	107	116	125·5	136	147	160·5	178	198·5	—

The solubility of sodium nitrite is diminished by the presence of sodium sulphate. A solution saturated at 16° C. con tains 42·3 per cent. of calcium nitrite. Silver nitrite forms double salts with some nitrites, viz., $K_2Ag_2(NO_2)_4,H_2O$, $Na_2Ag_2(NO_2)_4,H_2O$ and $BaAg_2(NO_2)_4,H_2O$. The temperatures of decomposition of some nitrites are: $NaNO_2$, 320°; KNO_2, 350°; $LiNO_2$, 185°; $Ba(NO_2)_2$, 235°; $Sr(NO_2)_2$, 240°; $Ca(NO_2)_2$, 220° C. (see also this J., 1905, 26). Nitrogen peroxide acts on alkali and alkaline-earth nitrites in two different ways:—

$$NaNO_2+NO_2=NO+NaNO_3;$$
$$2NaNO_2+NO_2=N+2NaNO_3.$$

Solid alkali and alkaline-earth nitrites are not affected by oxygen at temperatures below their decomposition point. Aqueons solutions, also, are stable, if perfectly neutral, but in presence of acid the nitrites are slowly oxidised by air:—

$$3HNO_2=HNO_3+2NO+H_2O;$$
$$2NO+2O+H_2O=HNO_3+HNO_2.$$

—A. S.

Calcium cyanamide; Presence of nitride in ——. C. Manuelli. Annali Chim. Appl., 1914, **1**, 110—114.

Samples of calcium cyanamide of different origin contained up to 0·56 per cent. of nitride, as determined by distilling with water and magnesia under diminished pressure at 35°—40° C., and absorbing the liberated ammonia.—A. S.

Manganous arsenate jellies; Preparation and properties of ——. E. Deiss. Kolloid-Zeits., 1914, **14**, 139—146.

One part of a solution of manganous chloride (100 grms. $MnCl_2,4H_2O$ per litre) is diluted with an equal volume of water and from 1 to 10 parts of a solution of mono-potassium arsenate (90 grms. per litre) added rapidly: the whole soon sets to a stiff colourless clear jelly. The jelly becomes slightly opalescent on standing, and after some weeks, small pink crystals appear in places and these gradually unite to spherolites of 1—2 mm. diam. The formation of crystals takes place more rapidly if the jelly is heated on a steam-bath, evaporation being prevented: in 4—6 hours, it changes into a mass of light violet-pink leaflets of the composition, $MnHAsO_4,H_2O$, very sparingly soluble in water.—A. S.

Chromium hydroxide; Absorption of carbon dioxide from the air by ——. M. Z. Iovitchitch. Comptes rend., 1914, **158**, 872—874.

Pure chromium hydroxide, precipitated by ammonia, and entirely free from alkali, slowly absorbs carbon dioxide from the air, attaining eventually a constant composition represented by the formula $[Cr_2(OH)_5]_2CO_3,8H_2O$, This monocarbonate loses water but retains its carbonic acid when dried at 100° C.—G. F. M.

Chromous oxide. T. Dieckmann and O. Hanf. Z. anorg. Chem., 1914, **86**, 301—304.

Chromous oxide (CrO) was obtained as a black powder by warming chromium amalgam with dilute nitric acid. It was insoluble in this and in dilute sulphuric acid, but dissolved in dilute hydrochloric acid, with evolution of hydrogen. At 1000° C. carbon monoxide converted it into a mixture of carbide and chromic oxide, and hydrogen reduced it to the metal. Chromic oxide was not affected by hydrogen or carbon monoxide even at 1300° C.

—F. Sodn.

Arsenides and phosphides of chromium; Some ——. T. Dieckmann and O. Hanf. Z. anorg. Chem., 1914, **86**, 291—295.

By heating finely divided chromium (prepared from chromium amalgam) with an excess of the metalloid in sealed tubes (see this J., 1911, 1216), Cr_2As_3 and Cr_2P_3 were obtained, and these yielded CrAs and CrP respectively, when heated in a current of hydrogen. All are grey in colour and insoluble in mineral acids.—F. Sodn.

Scandium. R. J. Meyer, A. Wassjuchnow, N. Drapier, and E. Bodländer. Z. anorg. Chem., 1914, **86**, 257—290.

Scandium oxide is best prepared from the oxide residues (0·3 per cent. Sc_2O_3) obtained in the manufacture of tungstic acid from wolframite from the Erzgebirge district of Saxony. For its preparation in quantity, free from thorium, the sodium carbonate method (this J., 1910, 1008) or the ammonium tartrate method (this J., 1912, 720) is preferred. A number of salts and double salts (complex fluorides, sulphates, and oxalates) are described, and it is pointed out that scandium differs from the other rare earth metals in its more pronounced electronegative character, its salts showing a marked tendency to hydrolyse and to form stable complex double salts.—F. Sodn.

Lead peroxide; The Lux method for the determination of ——. A. Ipiens. Z. anal. Chem., 1914, **53**, 261—265.

The modification of the Lux method recommended by Chwala and Colle (this J., 1911, 802) gives high results owing to the combined influence of the lead nitrate and free nitric acid on the permanganate titration of the excess of oxalic acid. The author recommends neutralisation of the nitric acid with sodium hydroxide, and acidification with sulphuric acid previous to the titration. The electrolytic determination of lead as peroxide also gives high results owing to adhering lead nitrate, or combined water, as suggested by A. Fischer ("*Elektroanalyt. Schnellmethoden*") and R. O. Smith (this J., 1905, 1191), and not to the production of higher oxides of lead as assumed by Hollard (this J., 1904, 207).—G. F. M.

Hydrogen peroxide; Synthesis of 100 per cent. —— *by means of the silent electric discharge.* P. M. Wolf. Z. Elektrochem., 1914, **20**, 204—219.

The experiments extend the data and conclusions of Fischer and Wolf (this J., 1911, 1250). The lower limit of pressure for the explosion of electrolytic gas was about 146 mm. With electrolytic gas below this pressure not more than 17 per cent. of the oxygen could be converted into hydrogen peroxide by means of the silent discharge. The limits of composition for the explosion of hydrogen-oxygen mixtures at ordinary pressure were from 5·45 per cent. to 94·7 per cent. of hydrogen by volume. Working outside these limits with excess of hydrogen the author determined the most favourable conditions for the formation of hydrogen peroxide in his apparatus, viz., low temperature, current exciting the coil 4·6 amp., velocity of gas through zone of discharge 400 c.c. per hour, moist gases, oxygen percentage 3·5 per cent. At —80° C., *i.e.* with gases practically free from moisture, but with the other conditions as described above, a 99·9 per cent. yield of peroxide, which must therefore have been free from water was obtained. Electrolytic gas diluted with carbon dioxide till no longer explosive, gave yields of only about 4 per cent. Very small quantities of hydrogen peroxide were obtained by passing non-explosive mixtures of hydrogen with excess of oxygen over glowing wires of various metals. It is concluded that in the reaction between hydrogen and oxygen, the first stage is the direct formation of hydrogen peroxide, which may be followed more or less completely by secondary reactions producing water.—W. H. P.

Acid tanks; Mastic lining for ——. Min. and Eng World, March 28, 1914. [T.R.]

Trinidad asphalt mastic has been found to be a satisfactory material for lining concrete tanks which are subjected to the action of sulphuric acid. Many other materials were tried, but none was found suitable except the asphalt mastic, which showed no deterioration after a year's test.

Sulphate of ammonia in Germany. U.S. Consular Rept. March 30, 1914.

Active competition has started in Germany between two groups of manufacturers of sulphate of ammonia comprising the German ammonia combination of Bochum on one side and the Badische Company on the other. The Bochum Company, a combination of gas and coke works, produces sulphate in the usual manner while the Badische Company produces it by a new method, and has cut prices, being in a position, it is stated, to produce much larger quantities if a market can be found. At present the Bochum combination is now urging buyers to sign agreements pledging themselves not to deal with middlemen, in return for which they are to be allowed a 10 per cent. discount at the end of the year on running contracts.

The quantities of sulphate of ammonia manufactured in Germany were estimated to have been 500,000 metric tons in 1912, and 418,000 tons in 1911. Of this quantity the German ammonia combination in Bochum disposed of about 300,000 tons in 1912 and about 245,000 tons in 1911. The producing concerns in upper Silesia, Rhineland, and Westphalia are said to be willing to engage in competitive contest, claiming that the cost of manufacturing artificial ammonia is more than the cost of producing ammonia in coke and gas works.

Alkali fusions. [*Formation of acetic acid from acetylene.*] Feuchter. *See* IV.

Determination of free sulphurous acid in the presence of thiosulphate or of sulphuric acid. Sander. *See* XXIII.

Patents.

Sulphuric acid apparatus; Structure for carrying the lead chambers or plates of ——. E. Hartmann (vorm. E. Hartmann und F. Benker) Ges. m. b. H., Frankfort-on-Maine, Germany. Eng. Pat. 17,035, July 24, 1913. Under Int. Conv., July 30, 1912.

The chambers or plates are suspended from trestles, preferably of iron, by means of tension rods which are adjustable as regards length and tension and adapted to engage removable carrying bars on the lead plates.
—F. Sodn.

Hydrochloric acid pickle liquors; Apparatus for treating waste ——. G. H. Starck, Waukegan, Ill. U.S. Pat. 1,090,173, March 17, 1914.

A hearth for containing a liquid, a retort for containing a wet solid, and fire grates are so arranged that flames pass from the grate immediately into contact with the retort and then over the hearth. The retort is open at both ends for the passage of air, the vapours evolved passing with the flames over the hearth. Means are provided for regulating the supply of air and the supply and discharge of solid material. A recovery chamber, fitted with water spray, receives the gaseous products.
—F. Sodn.

Acid liquids; Process for the [*continuous*] *distillation of* ——. W. Hof. Fr. Pat. 463,208, Sept. 19, 1913. Under Int. Conv., Sept. 20, 1912.

The acid flows along a slightly inclined tube of quartz-glass or other refractory glass, in the upper part of which it is vaporised. The lower portion of the tube is cooled and serves as a condenser, the residues and non-vaporised acid being tapped off at a point between the heated and cooled portions.—F. Sodn.

Boron nitride; Processes of making ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 16,468, July 17, 1913.

A mixture of boric anhydride and sodium cyanide or of other boron and cyanogen compounds, is heated at a temperature (about 2000° C.) at which all by-products (such as sodium carbonate) are volatilised, until fumes cease to be evolved. The product is pure and stable.
—F. Sodn.

Aluminium nitride; Process for the manufacture of ——. O. Serpek, Paris. Eng. Pat. 24,731, Oct. 30, 1913.

A current of nitrogen, carrying a mixture of carbon and alumina or aluminous material in suspension, is submitted to the combined heat of an exothermic reaction and of an electric arc. For example, the finely divided mixture may fall into a current of heated air (in which the carbon is partially burnt) and then pass, with the nitrogen and combustion products, through an arc flame.
—F. Sodn.

Nitrides; Process of continuous manufacture of ——. Gebr. Giulini Ges. m. b. H. Fr. Pat. 463,232, Sept. 29, 1913. Under Int. Conv., Dec. 6, 1912.

A mixture of alumina (or corresponding oxide or hydroxide and carbon, together with oxides, hydroxides, or salts of alkali, alkaline-earth, or analogous metals (to facilitate reaction) is heated in a current of nitrogen in an apparatus lined with carbon. The lining prevents fusion.—F. Sodn.

Alumina; Method of making ——. H. T. Kalmus and W. L. Savell, Kingston, Ontario. U.S. Pat. 1,090,479, March 17, 1914.

Aluminous material is treated with sulphur dioxide in presence of water. The alumina dissolves as a relatively unstable compound or compounds with sulphur dioxide, and is precipitated by desulphiting the solution (*e.g.*, by heating). If silica also be dissolved and precipitated with the alumina, the precipitate is again treated with sulphur dioxide and a small amount of water so as to dissolve only the alumina which is then reprecipitated as before.
—F. Sodn.

Nitrogen compounds; Apparatus for manufacturing ——. T. Fujiyama, Tokyo, Japan. U.S. Pat. 1,090,391, March 17, 1914.

Material to be treated is fed, preferably in a thin layer, on to a travelling support within a closed chamber, the space between the support and the wall of the chamber being heated electrically. A discharge conduit, surrounded by a cooling jacket, extends from the chamber, and serves also for the introduction of nitrogen, which flows through the chamber over the thin layer of heated material.—F. Sodn.

(1) *Nitric oxide, by electric oxidation of atmospheric nitrogen,* (2) *concentrated nitric acid, by treatment of the diluted oxides of nitrogen obtained by electric oxidation of atmospheric air,* (3) *concentrated nitric acid, by treatment of dilute nitric acid; Production of* ——. C. Rossi. Fr. Pats. 463,821, 463,825, and 463,830, Oct. 20, 1913. Under Int. Conv., Oct. 22, 1912.

(1) A mixture of oxygen and nitrogen is submitted to the action of arcs, formed between electrodes of silicon and aluminium, or other metals of which the oxides have no destructive catalytic action on the nitric oxide formed. Preferably the electrodes are composed of alloys of aluminium and silicon with alkali and alkaline-earth metals, such as calcium, barium, cerium, rubidium, etc., or with thorium, the oxides of which catalytically promote the formation of nitric oxide. (2) Gases resulting from the combustion of atmospheric nitrogen, or those leaving the absorption towers employed for recovery of the nitric acid produced, are charged with water in an atomised condition and submitted to electrostatic precipitation, with a continuous current at high voltage, *e.g.*, by passage between two aluminium plates, one smooth and the other covered with cotton or asbestos fibre; with a potential difference of 20,000—40,000 volts, nitric acid of any desired concentration up to 42° B. (sp. gr. 1·41) can be obtained. (3) Concentration up to 42° B. (sp. gr. 1·41), with a yield of 98 per cent., is effected *in vacuo*.—F. Sodn.

Zinc; Process for extracting —— *from solutions of zinc sulphate or other zinc salt.* R. D. Lance. Fr. Pat. 463,614, Dec. 21, 1912.

Improvements on Fr. Pats. 437,889 of 1911 and 451,680 of 1912 (this J., 1912, 535 and 1913, 663). The solution is treated with calcium sulphite in presence of an excess of sulphurous acid (*e.g.*, by intimately mixing with the calculated quantity of limestone and treating with sulphur dioxide), in such wise that free lime is at no time in contact with the zinc salt and that all the zinc remains in solution as bisulphite. After filtering, the zinc is precipitated as normal sulphite, preferably with zinc oxide. Pure zinc oxide is obtained by calcining the precipitate.—F. Sodn.

Lyes containing potassium sulphate and magnesium sulphate, obtained in the working up of crude potassium salts and the like; Treatment of ——. Heldburg, A.-G. für Bergbau, bergbauliche und andere industrielle Erzeugnisse. Ger. Pat. 270,620, Nov. 10, 1912.

The lyes are treated with a quantity of calcium chloride or other soluble calcium salt corresponding to their content of magnesium sulphate: $K_2SO_4,MgSO_4+CaCl_2+H_2O=K_2SO_4.CaSO_4,H_2O+MgCl_2$. The precipitated double salt (syngenite) is calcined and can then be used directly as a fertiliser or mixed with high-grade potassium sulphate. —A. S.

Sulphuric anhydride; Process for producing —— according to the contact process. Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 15,165, July 1, 1913. Under Int. Conv., July 13, 1912.

See Fr. Pat. 442,820 of 1912; this J., 1912, 1032.—T. F. B.

Potassium and sodium compounds; Method for extracting —— from silicates which contain alkalis. A. Messerschmitt, Stolberg, Germany. U.S. Pat. 1,091,230, March 24, 1914.

See Ger. Pat. 254,544 of 1911; this J., 1913, 194.—T. F. B.

Sulphites or bisulphites; Process of manufacture of ——. *Process of manufacture of solid sulphites or bisulphites of homogeneous chemical constitution.* R. Friedrich, Glösa, Germany, and F. Hirsch, Vienna. U.S. Pats. 1,091,325 and 1,091,429, March 24, 1914.

See Fr. Pat. 421,610 of 1910; this J., 1911, 542.—T. F. B.

Nitrogen; Process of fixing ——. J. E. Bucher, Coventry, R.I., Assignor to Nitrogen Products Co. U.S. Pat. 1,091,425, March 24, 1914.

See Fr. Pat. 455,799 of 1912; this J., 1913, 943.—T. F. B.

Method of heating electric furnaces, more particularly applicable to the manufacture of aluminium nitride. Fr. Pat. 463,390. *See* XI.

VIII.—GLASS; CERAMICS.

Specific heats of some ceramic bodies from observations at two temperatures. W. Steger. Silikat-Zeits., 1914, 2, 51—54.

The bodies were heated to 200° C. and to 400° C. respectively, and the final temperature of the calorimeter was approximately 20° C. The specific heats of: a fireclay body with Marquardt-mixture as binding agent (A), hard porcelain (B), Marquardt body burnt at cone 09 (C), the same burnt at cone 15 (D), and a magnesia body (E), were as follows:—

	A	B	C	D	E
200° C. ...	0·209	0·202	0·212	0·212	0·246
400° C. ...	0·228	0·221	0·229	0·229	0·264

—H. H. S.

Patent.

Porcelain articles [insulators]. J. A. and B. A. Jeffery, Detroit, Mich., U.S.A. Eng. Pat. 16,396, July 16, 1913.

"Blanks" of green clay are allowed to stand until they become hard, bone-dry, and non-plastic, and are then shaped by grinding, and fired. Each blank is provided with a central bore, either before or after drying.—B. N.

IX.—BUILDING MATERIALS.

Tar treatment of roads. Revision of Road Board specifications. See III.

Patents.

Bricks, cement, and the like; Process and apparatus for making ——. The Hewitt Patent Kiln Co., Ltd., London, and W. W. Hewitt, Greenhithe. Eng. Pat. 144, Jan. 2, 1913.

Slurry is dried on travelling trays, forming the top of a furnace, and is moulded into bricks or the like whilst hot, the bricks are piled on trucks and heated in a tunnel, and the trucks are conveyed through the furnace to a cooling tunnel, beneath or beside the first tunnel, which is thereby heated.—F. Sodn.

Stones and plastic material; Process for glazing natural and artificial ——. P. Fenaroli, Milan, and Soc. Anon. "Saces," Genoa, Italy. Eng. Pat. 2197, Jan. 27, 1913.

The stone is sprayed with a glazing composition of sodium silicate and pulverised marble or the like, the glazed surface "varnished" with a solution containing sodium silicate, then heated to about 150° C., and submitted to successive treatments with water and slightly acidulated baths containing free acids (sulphuric acid, fluosilicic acid, etc.) or readily hydrolysable salts (preferably of aluminium), whereby soluble salts are removed and the glaze rendered resistant towards atmospheric changes.—F. Sodn.

Tar macadamised roads; Method of preparing stones for making ——. Ges. für Teerverwertung m. b. H., Duisburg-Meiderich, Germany. Eng. Pat. 23,918, Oct. 22, 1913. Under Int. Conv., Oct. 23, 1912.

Drying, cleaning, and tarring is effected in a single operation by treating the cold stones with an excess of hot tar (preferably at 120°—150° C.), the excess being ultimately drawn off for use again.—F. Sodn.

Concrete structures; Processes of hardening ——. S. W. Flesheim, Cleveland, Ohio, U.S.A. Eng. Pat. 24,420, Oct. 28, 1913. Under Int. Conv., Aug. 11, 1913.

A dry mixture of cement and irregular shaped grains of tenacious metal, preferably iron, is applied to the surface of the concrete before its setting, the mixture being thoroughly rubbed into contact with the surface and finally worked to a smooth burnished surface with a trowel. A first troweling, with feeble pressure, is given immediately after the mixture has been floated upon the concrete, and a second troweling, with heavy pressure, after setting has commenced.—F. Sodn.

Portland cement; Process for the application of slags or residues from the preparation of alloys of manganese, silicon and iron in the electric furnace to the manufacture of artificial ——. J. M. Viélajus. Fr. Pat. 463,362, Oct. 7, 1913

The material is incorporated with the required proportion of lime and treated by the usual methods for the production of cement.—W. E. F. P.

Mortar from lime and sand; Manufacture of ——. C. Czarnikow. Ger. Pat. 270,516, Oct. 27, 1912.

The lime is slaked hot in presence of the sand and of cryolite or a mixture of sodium fluoride and aluminium sulphate. The resulting mortar has improved hydraulic properties.—A. S.

Mortar which does not effloresce ; Manufacture of ——. Mörtelwerk Waidmannslust Nester und Co. Ger. Pat. 270,815, Oct. 27, 1912.

A mixture of lime and sand or powdered stone is treated with strontium carbonate and boracite and the lime slaked hot.—A. S.

Cements or agglomerates for constructional purposes. M. J. and G. H. Langlois, Paris. Eng. Pat. 16,636, July 19, 1913. Under Int. Conv., July 20, 1912.

See Fr. Pat. 446,380 of 1912 ; this J., 1913, 144.—T. F. B.

Making non-explosive preparations [nitro-compounds for impregnating wood]. Fr. Pat. 463,288. *See* III.

X.—METALS ; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Phosphorus in iron and steel ; Determination of ——. H. Phillips. Chem. News, 1914, **109**, 170—171.

The greyish stain appearing on the dried filter-paper containing the phosphomolybdate precipitate in the direct gravimetric determination of phosphorus is attributed to slight reduction of the MoO_3, and to obviate it the following modified process is recommended :—The phosphate solution is treated with 30 c.c. of nitric acid (1·2 sp. gr.), 5 c.c. of ammonia (sp. gr. 0·880), diluted with its own volume of water, and 30 c.c. of nitromolybdate solution (Brearley and Ibbotson, Anal. of Steel Works Materials, p. 56). The mixture is vigorously agitated, warmed to 40° C., and after one hour filtered through a 9 cm. close-textured paper. The precipitate is washed free from soluble salts by 2 per cent. nitric acid, then free from acid with water, dissolved by aqueous ammonia, filtered through the same paper into a light weighed dish, evaporated to dryness and the residue dried in the water-oven till of constant weight. The factor 0·0151 is used, instead of 0·0165, as usual.—J. L. F.

Iron, tungsten, carbon, and iron, nickel, carbon ; The chemical and mechanical relations of ——. J. O. Arnold and A. A. Read. Inst. Mech. Eng., March, 1914. [Advance proof.]

Tungsten steels (W 2·38 to 26·29, C about 0·7 per cent.). The carbides were separated and estimated by making the samples anodes in an electrolyte of dilute hydrochloric acid. Steels with W 26·29, 21·15 and 14·96 per cent. gave residues consisting of mixtures of WC and Fe_2W ; with 9·74 per cent. W. the residue consisted of $19WC + Fe_3C$; and with 5·37 and 2·36 per cent. W, of the same carbides with free carbon. The effect of tungsten is similar to, but much less marked than, that of vanadium (this J., 1912, 492) *e.g.* to displace entirely Fe_3C, about 11 per cent. W is required as compared with 5 per cent. V. High tungsten accelerates the segregation of tungsten carbide in sorbitic tungsten pearlite into tungsten cementite, just as high vanadium hastens the segregation of vanadium cementite (V_4C_3). Whilst vanadium pearlite (like iron pearlite) is transformed with a marked thermal abruptness into vanadium hardenite, the transformation of tungsten pearlite spreads over the very wide range of about 300° C. before completion : there was no evidence of the formation of tungsten troostitic pearlite. *Nickel steels.*—In ordinary (somewhat manganiferous) structural steels containing Ni up to about 7 per cent., the nickel is not associated with the carbon, but is alloyed with the iron and manganese. Tests made on very pure iron-nickel alloys indicated the existence of a definite alloy, Fe_7Ni, which is remarkably hard and tough. An alloy with Ni 13 per cent. gave a yield point of 59 tons and a maximum stress of 88 tons per sq. in. Alloys with Ni 7 and 33 per cent. both gave a yield point of about 30, and a maximum stress of about 38·5 tons per sq. in. No evidence of a double carbide of iron and nickel was obtained. There appears not to be a nickel pearlite, the carbide (Ni_3C) always being in solid solution as nickel hardenite, which on annealing or rolling, precipitates practically all its carbon as graphite, owing to the remarkably unstable character of the carbide. Fe_7Ni is very tough though machinable, but a steel with Ni about 13 per cent. and C 0·55 per cent. could not be turned or drilled, being rendered harder by the dissolved Ni_3C.—T. St.

[Gold and silver.] Cyanide precipitate ; Treatment of ——. H. A. Megraw. Eng. and Min. J., 1914, **97**, 505—509, 606—612.

The elimination of the zinc from cyanide precipitate by an acid treatment or volatilising roast is now generally omitted, the material being melted down at once into doré bullion which is parted. Reverberatory lead smelting of the precipitate and cupellation of the lead bullion is practised on the Rand and in New Jersey, U.S.A. ; smelting and cupelling may be carried out in the same furnace by using a different bottom for each operation. The introduction of oil-fired tilting furnaces has resulted in a quicker and cheaper process : the Monarch-Rockwell is a double-chamber furnace heated with an oil burner through a hollow trunnion upon which it turns for discharging the metal. In the Merrill process used at the Homestake Mill, S.D., the zinc is extracted by sulphuric acid ; high-grade precipitate is briquetted and cupelled direct, low-grade material is melted into lead bullion in a circular water-jacketed blast furnace having a lead well ; copper if present is recovered in a forehearth as matte by adding pyrite to the charge. Electric arc furnaces have been successfully applied to precipitate smelting ; the melting is rapid, especially if the material has been previously dried. Working costs of the various methods of treatment are given.—W. R. S.

Zinc ; Electro-deposition of —— *at high current densities.* J. N. Pring and U. C. Tainton. Chem. Soc. Trans., 1914, **105**, 710—724.

At current densities up to 40 amps. per sq. dcm. the satisfactory electrodeposition of zinc can be effected in the presence of free acid up to 15 grms. H_2SO_4 per 100 c.c., at which concentration the efficiency is highest. The potential differences are about 5 volts with lead and 3 with zinc anodes. The presence of colloids causes the production of smooth bright-surfaced deposits and permits the use of higher current densities. A strong retardation of the iron was observed, a deposit containing only about 0·1 per cent. Fe being obtained from an electrolyte containing 1·0 per cent. Fe. (See also Eng. Pat. 7235 of 1911 ; this J., 1912, 780.)—J. L. F.

Delta metal ; Analysis of —— *by the electrolytic method.* R. Belasio and M. Marchionneschi. Annali Chim. Appl., 1914, **1**, 127—133.

One grm. of the alloy is dissolved in 10—12 c.c. of nitric acid of sp. gr. 1·2, the solution filtered, evaporated with 5 c.c. of sulphuric acid (1 : 1), heated with 30 c.c. of water, cooled, and treated with 5 c.c. of 95 per cent. alcohol. After 1 hour, the lead sulphate is filtered off, washed with a mixture of water, alcohol, and sulphuric acid (60 : 10 : 0·5 c.c.), dried and weighed. The filtrate, after distilling off the alcohol, is diluted to 150 c.c., and the copper deposited electrolytically (ND_{100}=0·1—0·2 amp., 1·7—2 volts). Any manganese dioxide deposited on the anode is dissolved by adding a few drops of hydrogen peroxide and heating, and the solution, containing zinc, iron, manganese and aluminium, is concentrated to 30—40 c.c., and added gradually to a solution of 10 grms. of sodium hydroxide in 30—40 c.c. of water, whereby iron and manganese are precipitated. The solution is filtered into 100 c.c. of 20 per cent. sulphuric acid, the precipitate washed with dilute sodium hydroxide, then dissolved and re-precipitated. The iron and manganese may be separated electrolytically (see this J., 1912, 926). The solution is acidified with sulphuric acid, concentrated to 200—250 c.c., made alkaline with caustic soda, and then slightly acid with 20 per cent. formic acid, and the zinc deposited electrolytically at 40°—50° C. (ND_{100}= 1—1·5 amp., 4—5 volts), using a rotating anode. The aluminium is determined as oxide.—A. S.

Aluminium and its light alloys; Analysis of commercial ——. R. Belasio. Annali Chim. Appl., 1914, 1, 101—110.

THE finely-divided sample (2—4 grms.) is mixed with about 5 times its weight of tartaric acid and a few c.c. of water, and dissolved in dilute hydrochloric acid. The solution is heated with 2—3 c.c. of nitric acid, treated with excess of caustic soda and then with hydrogen sulphide to precipitate copper, lead, iron, manganese, zinc and cobalt, whilst aluminium and tin remain in solution. If the sulphide precipitate be considerable it should be dissolved and re-precipitated; the metals present are determined by known methods. The solution is diluted to a known volume, and an aliquot part is treated with 20—25 c.c. excess of hydrochloric acid, the tin sulphide dissolved with the aid of potassium chlorate, 25—30 grms. of ammonium oxalate added, and the tin determined electrolytically at 50°—60° C., using a current density, ND_{100}= 1 amp. at 3—3·5 volts. If nickel be present it is determined with dimethylglyoxime (this J., 1907, 643, 1217), before precipitating with hydrogen sulphide as above. From another portion of the sample, aluminium and iron are precipitated as oxides, the aluminium taken by difference, the iron determined with "cupferron" (this J., 1910, 115, 721). Silicon is determined by Handy's method (J. Amer. Chem. Soc., 1896, **18**, 736) and sodium by Moissan's method (this J., 1896, 136).—A. S.

Silver and tin; The ageing of alloys of ——. W. A. Knight. Chem. Soc. Trans., 1914, **105**, 639—645.

THE ageing of filings of alloys of silver and tin (see this J., 1913, 1112) was not accompanied by a change in weight nor by superficial oxidation. A contraction in volume of about 0·4 per cent., however, was observed.—J. L. F.

Sodium; Studies on the preparation of ——. *II.* B. Neumann. Z. angew. Chem., 1914, 194—200.

CAUSTIC soda containing 12—17 per cent. of sodium carbonate, when electrolysed in the apparatus and under the conditions described previously (this J., 1914, 263), gave current yields of about 63 per cent. The presence of sodium chloride lowered the efficiency. In each case the highest yields were obtained with eutectic mixtures. The theoretical explanation of these results and their bearing on the technical manufacture of sodium are discussed, and it is stated that better results would be obtained if the caustic soda, as free as possible from sodium chloride, were completely dehydrated before use, and more care taken to control the temperature of the bath and removal of water at the anode.—J. L. F.

PATENTS.

Blast-furnaces; Working of ——. C. Semmler. Fr. Pat. 463,524, Oct. 11, 1913.

THE coke is charged into the furnace in a red-hot condition from a closed vessel lined with refractory material. —W. E. F. P.

Cast-iron; Malleable metal product from ——. E. A. Custer, Assignor to The Custer Sandless Casting Co., Philadelphia, Pa. U.S. Pat. 1,086,652, Feb. 10, 1914.

MALLEABLE iron castings are obtained, without annealing, from ordinary molten foundry iron, comparatively high in silicon and low in combined carbon, in a permanent metal mould. After setting, the casting is removed from the mould and allowed to cool under normal atmospheric conditions.—T. ST.

Iron; Method of working pure ——. R. B. Carnahan, jun., Assignor to International Metal Products Co., Middletown, Ohio. U.S. Pat. 1,090,115, March 10, 1914.

THE working of the metal, commenced at a temperature above the zone of non-malleability, is suspended until the metal has cooled to a temperature below this zone, and then continued.—W. E. F. P.

Steel; Refining ——. A. Hethey, London. U.S. Pat. 1,089,410, March 10, 1914.

THE steel is treated in an open-hearth or electric furnace with an oxidising slag, manganese being added from time to time to prevent the formation of iron oxide in the metal; and the slag is then solidified by addition of lime or dolomite and the refining completed at an increased temperature.—W. E. F. P.

Galvanising, or like coating of wire, hoops, sheets, and the like. H. H. Field, Grappenhall, Chester, M. Howarth, Warrington, and E. A. Atkins, Liverpool. Eng. Pat. 27,641, Nov. 30, 1912.

After treatment with acid, the (iron) wire, etc., is subjected to electrolytic action in an aqueous solution of zinc or stannous chloride, and then passed into the bath of molten zinc.—W. E. F. P.

[*Lead pipes, etc.*]. *Pumping apparatus for the manufacture of products of indefinite length from molten lead or other metals or alloys.* H. Debauge, Paris. Eng. Pat. 5639, March 6, 1913. Addition to Eng. Pat. 3944 of 1913, dated March 9, 1912 (this J. 1914, 320).

Molten lead is pumped into a die by pistons worked from a horizontal shaft. In each case the latter actuates a pitman resting in a slide-piston which acts on the forcing piston through the medium of a ball. The upper end of each pitman is constructed with a fork which embraces the lower part of an eccentric on the operating shaft. The pitman thus acts only by thrust, and is raised by a strong spring disposed under the head of the piston. If any piston jams, the action of the others is thus not interrupted. Several cylinders are contained in a single block divided at the upper part to allow the molten metal to surround the cylinders and so obviate the effects of unequal expansion. Means are provided for keeping the pump cylinders vertical during normal working, and for tilting the cylinders and casing enclosing the operating mechanism as a whole about the shaft in either direction, in order to allow of air being replaced by lead in the cylinders and in a bell placed over the die when the pump is started, and also permit of the pump being raised out of the molten bath for inspection during working. Connected with the outlet from the pump cylinders is a cylinder of small section containing a rod, the upper end of which is acted on by a strong spring in compression, the whole acting as a pressure-regulator, pressure-gauge, and safety-valve.—T. St.

Copper; Preparation of finely divided metallic ——. T. J. I. Craig and Peter Spence and Sons, Ltd., Manchester. Eng. Pat. 6161, March 12, 1913.

Finely-divided copper is obtained by electrolysis, using a copper anode, a lead cathode, and an electrolyte containing about 6 per cent. of titanic sulphate and about 6 per cent. of sulphuric acid. The titanic sulphate is reduced at the cathode, and the resulting titanous sulphate is re-oxidised in precipitating the dissolved copper in a finely-divided condition. To ensure the reduction of all the oxidised precipitating agent, current in excess of that passing through the copper may be used. Suitable conditions are:—2 to 4 volts per cell; density 30 to 40 amps. per sq. ft. of anode surface; cathode surface about 20 times as large as the anode surface.—T. St.

Metals or other materials; Means for ascertaining the hardness of ——. Rudge-Whitworth, Ltd., and H. L. Heathcote, Coventry. Eng. Pat. 6622, March 18, 1913.

The working of the various forms of apparatus proposed, depends upon the fact that the friction between the body to be tested and a hard rough surface, such as that of a file, is less for the harder body, the patentees having found that "if one of the surfaces be hard and rough, i.e. ridged or pointed, the friction, and consequently the angle when movement just begins, or continues, depends upon the degree of hardness of the softer surface."—T. St.

Magnetic separators. F. Krupp A.-G. Grusonwerk, Magdeburg-Buckau, Germany. Eng. Pat. 14,427, June 21, 1913. Under Int. Conv., July 15, 1912.

The strength of the magnetic field, across which the material travels, is adjusted by constructing the armature of adjustable disc-shaped members distributed along a horizontal axis about which the armature rotates, and by giving the underlying magnet an upper face inclined longitudinally.—B. N.

Magnetic separation of several kinds of materials in a single operation. F. Krupp A.-G. Grusonwerk. Fr. Pat. 464,156, Oct. 27, 1913. Under Int. Conv., Nov. 27, 1912.

The intensity of the magnetic field increases progressively in the direction in which the material is travelling, so that the latter is attracted to a moving cylinder and forms superposed layers, which fall off from the cylinder in the reverse order as the material passes out of the magnetic field.—B. N.

Metal [*Tungsten*]*; Method and apparatus for sintering* ——. R. B. Walling, Harrison, N.J., U.S.A. Eng. Pat. 14,795, June 26, 1913. Under Int. Conv., Oct. 7, 1912.

In sintering a rod of compressed tungsten by an electric current, in an inert atmosphere, the rod is held without lateral support between two relatively movable contacts, so that the whole of the rod is raised to a uniform sintering temperature. The lower contact is floated in mercury so that it continuously exerts a pressure on the end of the rod as the latter contracts during sintering, and thus maintains good electrical contact. Apparatus is described showing details of mounting. The copper containing bottle and the contacts are water-cooled.—T. St.

Furnace; Metal melting ——. I. Hall, Birmingham. Eng. Pat. 21,158, Sept. 18, 1913.

In a furnace for melting type-metal, etc., by means of a gas flame, the closed chambers above and below the melting pot are connected by external flues, so that the gases from the lower combustion chamber pass continuously over the surface of the molten metal.—W. E. F. P.

Metallurgical furnace. H. D. Hibbard, Plainfield, N.J. U.S. Pat. 1,089,377, March 3, 1914.

The furnace comprises a fire-chamber and a melting chamber, the inclined floors of which merge without substantial break into the floor of an interposed collecting chamber. The fuel is burned in the fire-chamber by a down-draught blast and the combustion gases pass through the collecting and melting chambers to the stack at the upper end of the latter; the floor of the collecting chamber slopes downwards to an outlet for the fused metal. In an alternative form, a combined ore and fuel charge is burned by means of a down-draught blast, and the fused metal received in a similar collecting chamber. The metal is thus removed from the reaction zone immediately after it is melted or produced.—A. S.

Alloy for white metal goods. H. Wilkins, Sheffield. Eng. Pat. 27,406, Nov. 28, 1913.

A hard white metal suitable for hollow-ware is composed of: Sn 100, Cu (2—4) 2·5, Sb (7—10) 8, Ni (0·5—6) 0·5, Mn (0·015—2) 0·125, parts by weight.—T. St.

Titanium and other alloys; Method of making ——. E. Kraus, Lynn, Mass., Assignor to General Electric Co. U.S. Pat. 1,089,773, Mar. 10, 1914.

The process depends upon reactions of the aluminothermic type. For example, alloys of aluminium and titanium are prepared by addition of aluminium to fused titanium oxide.—W. E. F. P.

Zinc furnace with integral condenser; Electric ——. J. Thomson, New York. U.S. Pats. 1,090,427 and 1,090,428, March 17, 1914.

(1) The charge rests on a horizontal resister bed of carbon, supported by a grate, underneath which is a chamber for receiving inert residual matter. The lower inner faces of vertical carbon terminals at the ends of the grate, are in contact with the resister, and are grooved to give an increased area of contact. The inner faces above the resister are separated from the charge by insulating blocks, and the outer faces of the terminals are in contact with the end walls of the resister chamber, the upper ends being connected by metallic electrodes with the power circuit.

(2) Parallel carbon resisters extending longitudinally are made porous so that fumes may pass through, and parallel condensing chambers containing broken coke are disposed in the same horizontal plane to receive the fumes from the resisters. The charge is supplied from galleries or pockets to one of the vertical faces of the resisters, the volatile products passing through the resisters to the condensers, whilst the inert residue falls towards the bottom of the reaction zone. A reservoir for the liquid zinc is provided under the condensers, and the latter have exits for gases at or near the top.—B. N.

Furnace ; Universal electric ——, combined with means for condensing zinc. J. Thomson, New York. U.S. Pat. 1,090,429, March 17, 1914.

The resister, extending in a longitudinal direction, and the transverse form of which is trapezoidal, rests on an open table or grate, towards which the charge-receiving floor slopes in a downward direction. A number of vertical spaced plates, extending transversely, and provided with abutments containing the terminals, rest on the grate, and underneath is a sump.—B. N.

Metals ; Process of precipitating and recovering ——. C. H. Urquhart, Newark, N.J. U.S. Pat. 1,090,661, March 17, 1914.

A solution containing dissolved metals is passed over granulated zinc contained in a closed chamber, the latter being completely filled with the solution to exclude air. The zinc is continuously subjected to agitation in order to remove the precipitated metals by abrasion.—T. St.

Ores ; Process and apparatus for extracting from pyritic and other ——, their metals in the metallic state or in the form of sulphates, sulphides or oxides. R. D. Lance. First Addition, dated Dec. 21, 1912, to Fr. Pat. 458,816, Aug. 17, 1912 (this J., 1913, 1075).

Before treatment with sulphuric acid, the ore is agitated with sulphurous acid to remove oxides, carbonates, etc. ; ores containing ferric oxide are agitated with hot sulphurous acid and air to form ferrous sulphate, which is subsequently calcined to produce sulphur trioxide. Sulphate solutions are treated with calcium chloride and the resulting chloride solution is treated with lime to precipitate compounds of the dissolved metals and regenerate calcium chloride.—W. E. F. P.

Bi-metal, e.g., steel with brass, with nickel or steel with any metal other than copper ; Process for making plates, sheets or leaves of ——. Soc. Internationale de Métallurgie Nouvelle. Fr. Pat. 463,155, Oct. 2, 1913.

Plates of brass, nickel, aluminium, etc., each having a polished face in contact with a thin sheet of copper, are placed in a pack and subjected to hydraulic pressure. The resulting composite plates are rolled into sheets and united (on the copper side) to the steel.—W. E. F. P.

Metals, ores, etc. ; Process and apparatus for the fusion of ——, by means of induced electric currents. S. Guggenheim. Fr. Pat. 463,233, Sept. 30, 1913. Under Int. Conv., Sept. 30, 1912.

The material is disposed between the poles of several magnetic circuits so that it is permeated by lines of force from each and absorbs sufficient energy to cause fusion. When a three-phase current is employed, the differences of phase between the magnetic fields are rendered unequal by means of auxiliary windings by which the directions of the lines of force are influenced locally ; opposite poles of the magnetic circuits have a smaller cross-sectional area than the material under treatment.—W. E. F. P.

Waste heat ; Process and apparatus for the utilisation of the ——, of slags and metallurgical works. C. Semmler. Fr. Pats. 463,298 and 463,300, Oct. 6, 1913.

(1) Molten slag is cooled in receptacles provided with hollow partitions through which water is circulated under a pressure sufficient to prevent vaporisation, the heat absorbed being transmitted to a heat accumulator. (2) A system of heat-absorbing units (similar to the above in principle) provided with a common pressure regulator in addition to the regulators of the separate units. The absorption and transmission of heat are effected in a series of steps corresponding to the different temperatures of the various sources of waste heat.
—W. E. F. P.

Iron and steel ; Prevention of corrosion of ——. H. Hanemann, Berlin-Wilmersdorf, and F. Hanaman, Berlin-Charlottenburg. Eng. Pat. 11,966, May 22, 1913. Under Int. Conv., June 1, 1912.

See Fr. Pat. 458,283 of 1913 ; this J., 1913, 1072.—T. F. B.

Case-hardening iron and steel articles ; Process for ——. C. Burian, Assignor to Gebr. Schubert, Berlin. U.S. Pat. 1,091,286, March 24, 1914.

See Eng. Pat. 13,805 of 1913 ; this J., 1913, 1016.—T. F. B.

Steel and iron ; Method for treating —— in their manufacture. C. R. Gostling, Eustis, Fla. U.S. Pat. 1,091,330, March 24, 1914.

See Eng. Pat. 17,869 of 1913 ; this J., 1914, 318.—T. F. B.

Welding powder for welding iron and steel. E. Eisengräber, Frankfort, Germany. U.S. Pat. 1,091,312, March 24, 1914.

See Eng. Pat. 17,046 of 1913 ; this J., 1914, 319.—T. F. B.

[Metallic] catalysts. K. H. Wimmer, Bremen, Germany, and E. B. Higgins, Wallasey. Eng. Pat. 4144, Feb. 18, 1913. Under Int. Conv., Feb. 19, 1912.

See Fr. Pat. 454,501 of 1913 ; this J., 1913, 870.—T. F. B.

Wires ; Process for sharpening the ends of fine ——. P. Friedrich, Wendenschloss, Assignor to J. Pintsch, A.-G., Berlin. U.S. Pat. 1,090,469, March 17, 1914.

See Ger. Pat. 251,836 of 1911 ; this J., 1912, 1173.—T. F. B.

Minerals ; Apparatus for washing ——. J. Dodds, Rutherglen. U.S. Pat. 1,091,047, March 24, 1914.

See Eng. Pat. 24,406 of 1911 ; this J., 1912, 863.—T. F. B.

Furnace for treating ore and the like. K. J. Beskow and A. Ramén, Helsingborg, Sweden. U.S. Pat. 1,091,182, March 24, 1914.

See Fr. Pat. 442,472 of 1912 ; this J., 1912, 932.—T. F. B.

Metals ; Separation of —— from zinc-bearing ores or compounds. E. A. Ashcroft, Balestrand, Norway. U.S. Pat. 1,091,269, March 24, 1914.

See Eng. Pat. 19,257 of 1911 ; this J., 1912. 931.—T. F. B.

Application of the slags or residues from the preparation of alloys of manganese, silicon, and iron in the electric furnace to the manufacture of artificial Portland cement Fr. Pat. 463,362. *See* IX.

Apparatus for removing iron from basic slag. Ger. Pat 268,500. *See* XVI.

XI.—ELECTRO-CHEMISTRY.

Alternating currents ; Chemical action stimulated by —— S. G. Brown. Roy. Soc. Proc., 1914, A90, 26—32.

In a simple voltaic cell consisting of a zinc anode ar a carbon cathode, the polarisation which soon ensu when the cell was joined through a low resistance circui was diminished or completely abolished by passing alternating current of suitable value through the cell. When the zinc anode was caused to project only slightly into the solution, something similar to polarisation was produced in an ordinary cell owing to the exhaustion of the electrolyte in the neighbourhood of the anode. This effect was also removed by a superimposed alternating current and the cell gave a greater output of current. Several metals (*e.g.* gold and platinum) normally insoluble in the liquid used were made to dissolve by the aid of alternating current. Similar stimulating effects were observed without the use of fluid dielectric.—W. H. P.

Electrolysis of barium chloride solutions with mercury cathodes. Fedotieff. *See* VII.

Synthesis of 100 *per cent. hydrogen peroxide by means of the silent electric discharge.* Wolf. *See* VII.

Patents.

Electrode holders for electric furnaces. F. Krupp A.-G., Essen, Germany. Eng. Pat. 5414, March 3, 1914. Under Int. Conv., Dec. 13, 1913.

The electrode, which passes with little clearance through a curb ring in the cover of the furnace, is attached to one end of a horizontal arm made in two parts, one portion guiding the electrode holder vertically by means of a standard. The second part is made adjustable so that it can be moved in the longitudinal direction of the arm, and also rotated about the longitudinal axis of the arm, thus enabling the electrode to be adapted to changing positions of the curb ring.—B. N.

Furnaces; Starting the arcs of electric ——. E. K. Scott, Bromley, Kent. Eng. Pat. 6136, March 12, 1913.

In an alternating current furnace, in which the arcs are struck and blown out periodically, the electrodes are provided with a nozzle supported on an insulating tube and with an adjustable diaphragm, for the purpose of admitting air to the arc. The electrodes are at such a distance from each other that the arc cannot be struck or maintained by the voltage of the power circuit alone, and a wire or conductor, supported by the nozzle, is placed in the gap between the electrodes, and connected through a condenser with a high-voltage and high-frequency supplementary circuit, a switch being provided in the latter circuit for striking, maintaining or stopping the arc. —B. N.

Furnace; Electric ——. S. Peacock, Chicago, Ill. U.S. Pat. 1,090,107, March 10, 1914.

The tapered, vertical furnace chamber has two fixed, horizontal electrodes near the base and an adjustable, vertical electrode at the top. The charge is introduced through two inclined pipes at the upper part, and "gas" through a pipe immediately below these. The air-tight outer casing is extended at the lower part to form, below the high-temperature zone of the furnace, a chamber (water-jacketed) provided with an outlet for the gases and from which the solid product is continuously removed by means of a screw conveyor.—W. E. F. P.

Furnaces; Method of heating electric ——, *more particularly applicable to the manufacture of aluminium nitride.* Soc. Générale des Nitrures. Fr. Pat. 463,390, Dec. 14, 1912.

The furnace consists of a slightly inclined rotating tube, through which the charge (a mixture of alumina and carbon, together with an excess of carbon, or iron or copper, to maintain its conductivity) passes downwards, meeting an ascending current of nitrogen. The charge serves as a heating resistance. The terminals are arranged at intervals along the length of the furnace, and are connected alternately with the two poles of the generator, so as to divide the furnace into a number of sections. As the material progresses through the furnace it becomes poorer in carbon, and the intermediate terminals are therefore arranged nearer to each other The intermediate terminals may be in the form of annular diaphragms, with orifices which gradually diminish in diameter, in order to increase the thickness of the layer in treatment as it becomes depleted of carbon and therefore less conductive.—B. N.

Batteries; Electric dry ——. S. Stern, London. From C. Hubert, New York. Eng. Pat. 6950, March 20, 1913.

The manganese compounds, obtained as a by-product in the manufacture of saccharin, are employed in the preparation of the depolarising agent for dry batteries. —B. N.

Battery cell; Electric ——. H. A. Thomas, Springfield, Ill. U.S. Pat. 1,090,763, March 17, 1914.

The anode consists of 92 per cent. of zinc shavings, 0·75 of bismuth, 7 of mercury and 0·25 of platinum, and the electrolyte contains one part of hydrochloric acid, one of sodium silicate, and eight of water, or as an alternative with sulphuric acid in addition, together with a depolarising liquid containing hydrochloric acid, sodium silicate, nitric acid and water.—B. N.

Galvanic elements; Electrolytic material for ——. A Lessing. Fr. Pat. 463,751, Sept. 11, 1913.

The electrolyte comprises zinc and ammonium chlorides together with mercuric oxide mixed with powdered tragacanth or salep, and with substances having the property of absorbing water, such as pumice, clay, etc. —B. N.

Electrode for ozoniser. C. Hemmerlin and J. Simonet. Fr. Pat. 463,711, Oct. 17, 1913.

The surface of a metallic plate is provided with a great number of projecting metallic points. The plate may be cylindrical, and the points, instead of being arranged regularly, may be disposed in appropriate divisions in order to prevent undue heating of the electrode.—B. N.

Gas with preservative properties; Production by means of the electric arc of a ——. International Ionising Process Co. Fr. Pat. 463,728, April 5, 1913.

Air is submitted to the action of the electric arc, and at the same time mixed with vapours of an organic vegetable substance, *e.g.*, such as are obtained from certain kinds of wood and which may be condensed at the ordinary temperature. The vapours are produced by bringing the wood in contact with the arc.—B. N.

Insulating products free from organic materials; Manufacture of light ——. A. C. D. Duchemin. Fr. Pat. 463,949, Dec. 30, 1912.

Volatile salts, such as ammonium carbonate, are mixed with plastic materials, such as plaster, clay, lime, cement, etc., and the mixture heated to about 100° C. to volatilise or dissociate the salts, thus producing a cellular structure in the material.—B. N.

Diaphragm for electrochemical or electro-osmotic purposes Ges. für Elektroosmose m. b. H. Ger. Pat. 271,001, April 15, 1913.

A diaphragm of regenerated cellulose, intended especially as a substitute for parchment paper.—A. S.

Heating articles in electric furnaces; Process for ——. F. Fischer, Charlottenburg, Germany. Eng. Pat. 17,490, July 30, 1913. Under Int. Conv., Nov. 5, 1912.

See Fr. Pat. 460,526 of 1913; this J., 1914, 90.—T. F. B.

Chemical, electro-chemical and electric treatment of plants, fields, sown seeds, crops, etc. Eng. Pat. 11,997. *See* XVI.

[Electrical] Treatment of milk or cream during churning. Eng. Pat. 6418. *See* XIXa.

XII.—FATS; OILS; WAXES.

Arachis oils; Residues from the refining of ——. G. Bouchard. Les Matières Grasses, 1914, **7**, 4027—4028.

In France arachis oils are refined with soda or ammonia The residues from the soda treatment are utilised directly in soap-making, but the paste-like deposit from the ammonia treatment (*pâtes d'arachide*) is treated with a mineral acid to separate the fat, which is then sold as "arachis oil, No. 2." The arachis pastes are soft and have a rancid odour and a green or brown colour; their price is based upon the oil-content. The disagreeable odour usually disappears in the manufacture of soap. "Arachis oils No. 2" are dark brown mixtures of fatty acids and neutral oil. Eight commercial samples gave the following results :—Free acids (as oleic acid) 55·8 to 70·2 per cent.; saponif. value, 192·4 to 195·9; glycerol, 3·18 to 4·60 per cent.; iodine value, 83·4 to 92·2; and unsaponifiable matter, 0·65 to 1·10 per cent. The values given by six samples of arachis pastes were :—Fat, 66·9 to 74·8 per cent. Characters of fat :—Free acids (as oleic acid) 51·1 to 75·9 per cent.; saponif. value, 193·2 to 196·1; glycerol, 2·50 to 5·08 per cent.; iodine value, 80·1 to 93·0; and unsaponifiable matter, 0·50 to 0·98 per cent. There are many abnormal arachis oils on the market derived, in particular, from Coromandel nuts. A few years ago these oils had an acidity of only 13 to 15 per cent. when freshly expressed, with a maximum in winter of 18 to 20 per cent. At the present time the acidity is frequently 27 to 28 and rarely less than 20 per cent., owing to the better quality of kernels being used for food purposes. These oils are sold as "industrial," "red," "soap" oils, "thickened" oils, etc. The "thickened" oils contain from 5 to 50 per cent. of impurities (seed débris) insoluble in carbon bisulphide. The arachis "margarines," which consist of the thick deposits from the oil tanks, contain from 25·3 to 29·4 per cent. of free acids (as oleic acid). As a rule they are darker and more acid than Coromandel oils.—C. A. M.

Fat as a by-product in the manufacture of glue from hide trimmings. H. Dubovitz. Seifensieder-Zeit., 1914, **41**, 341.

Hide trimmings are soaked in weak milk of lime for several weeks whereby a liquor is obtained from which glue is prepared by concentration. The residue is dried and, because of its nitrogen and lime content, is used as manure. It contains about 17 per cent. of fatty acids combined with lime and 6 per cent. of free fat which can be recovered by treating the material with sulphuric acid so as to decompose the lime soap and leave the mixture in a condition in which it can be satisfactorily treated with a fat solvent. This method of recovery is costly and the fat obtained contains about 4·5 per cent. of unsaponifiable matter. It is proposed to cheapen the process of recovery and obtain a fat containing less unsaponifiable matter by treatment with the "foots" obtained in the refining of oils with sulphuric acid, whereby the fatty constituents of both materials would be made available for extraction; by means of the Krebitz process of lime saponification (this J., 1906, 434) whereby the fatty material could be converted into soap; or by using the material as the source of lime required in the autoclave process of fat hydrolysis, its fatty constituents thus forming a proportion of the larger amount treated in the autoclave.—J. A.

Lipase of castor oil seeds; Activity of —— at low temperatures. A. Blanchet. Comptes rend., 1914, **158**, 895—896.

That the enzymic hydrolysis of fats in foodstuffs is possible at the usual refrigerator temperatures, is shown by experiments on the hydrolysis of castor oil by the enzyme contained in a suspension of the crushed seeds. At 0° C., 42 per cent., and at —5° C., 21 per cent. of the oil was hydrolysed in 24 hours.—G. F. M.

Unsaponifiable matter; Determination of —— in oils and fats. H. Salomon. Ber. deuts. Pharm. Ges., 1914, **24**, 189—193.

Klostermann's modification of the method of Marcusson and Schilling (see this J., 1913, 1118) for the detection of vegetable in animal fats can be further modified to allow of the simultaneous determination of unsaponifiable matter. 50 or 100 grms. of the oil are saponified with alcoholic potash, the soap dissolved in water, extracted with ether, the ether distilled off and the residue dried and weighed. The crude phytosterol or cholesterol so obtained is dissolved in hot alcohol and precipitated hot with excess of an alcoholic solution of digitonin, 1 grm. of crystallised digitonin being required for each 0·4 grm. of unsaponifiable matter. The precipitate is separated, acetylated and the phytosteryl acetate recrystallised as described by Klostermann (*loc. cit.*). The liquid unsaponifiable matter can be estimated in the filtrate from the digitonin precipitate by adding water, extracting with ether, distilling off the ether and weighing the dry residue. The relative proportions of solid (precipitated by digitonin) and liquid unsaponifiable matter in a number of oils and fats are tabulated.—T. C.

Patents.

Oil; Method of and apparatus for expressing —— from seeds, nuts and other oleaginous substances, and juice or fluid from fruits, herbs, flowers, peat and the like. A. W. Sizer, Kingston-upon-Hull. Eng. Pat. 29,331, Dec. 20, 1912.

Seeds, or other oil-containing or juicy substances are forced by means of a worm-screw into an annular chamber the walls of which are made up of juxtaposed staves or rings, having scratches or marks upon the surfaces in contact, the purpose of which is to allow the expressed oil or juice to pass through the walls of the chamber, whilst preventing the egress of solid material. The latter, in the form of a compressed mass, exudes through holes in a cap or die-plate on the front of the compression chamber, and may be cut up into lengths by means of a revolving knife rigidly attached to the spindle of the worm-screw and revolving in front of the die-plate.
—E. W. L.

Fats or oils from bones, seeds and other oleaginous substances; Process and apparatus used in extracting ——. W. Schmidt, Leipzig-Plagwitz, Germany. Eng. Pat. 5368, March 3, 1913.

The vaporised solvent leaving the extractor is fractionally condensed in a series of communicating compartments, at a temperature just below the b. pt. of the solvent or the respective fractions thereof, and the condensed liquids are led through pipes in each compartment to a common separator, where the solvent is freed from water before being returned to the extractor.—C. A. M.

Fats, rubber, waxes, etc.; Process of extracting —— by means of solvents. J. Margoles. Fr. Pat. 463,178, July 24, 1913.

The solvent (vapour or liquid) is circulated by aspiration, etc., either continuously or intermittently through the material contained in one or more extractors. It may be condensed, purified, and heated again before each passage through the apparatus —C. A. M.

Oils and the like; Apparatus for treating [hydrogenating] —— with gases, etc. C. Ellis, Montclair, N.J. U.S. Pat 1,084,203, Jan. 13, 1914.

Oil containing a catalytic agent is heated and drawn into an "inductor" at the top of a closed vessel, where it encounters a current of hydrogen, or gas containing hydrogen, under pressure, the mixture being then discharged tangentially against the bottom of the tank.

The application is in part a continuation of U.S. Pat. 1,059,720 of 1913 (this J., 1913, 612).—C. A. M.

Fats and oils; Preparation of a solid or liquid hydrolytic agent for ——. Sudfeldt und Co. Fr. Pat. 463,912, Oct. 22, 1913.

The impurities in sulpho-aromatic fatty acids which give a dark colour to the products of hydrolysis of fats and oils, are eliminated by converting the mixture of sulphonated acids into alkali salts and separating the sulpho-aromatic fatty acids from the sulphonated aromatic acids by the addition of salt. Fatty acids are then removed by extraction with a solvent (*e.g.*, petroleum spirit, carbon tetrachloride). A solid hydrolytic agent is obtained by adding a suitable metallic salt such as barium chloride to an aqueous solution of an alkali salt of a sulpho-aromatic fatty acid, and drying the precipitate.—C. A. M.

Fatty acids, their glycerides and other esters; Process for the preparation of saturated ——. F. Bedford and C. E. Williams, Sleaford, E. Erdmann, Halle, Germany, and Hydroil, Ltd., London. Eng. Pat. 28,981, Dec. 16, 1912. Addition to Eng. Pat. 29,612, Dec. 20, 1910.

See Addition of Aug. 19, 1913, to Fr. Pat. 436,295 of 1911; this J., 1914, 324.—T. F. B.

Preparation of india-rubber substitute. Eng. Pat. 4214. *See* XIV.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Cobalt-magnesium red. J. A. Hedvall. Z. anorg. Chem., 1914, **86**, 296—300.

An examination (chiefly microscopic) of the red products obtained by igniting mixtures of magnesia and cobalt oxide indicated that these, as in the case of Rinman's green (this J., 1914, 363), are solid solutions; the two oxides appear to form solid solutions in all proportions. —F. Sodn.

Oil of turpentine; The "heat number" of ——. A. Heiduschka. Chem.-Zeit., 1914, **38**, 441.

Twenty c.c. of a 2 per cent. solution of the turpentine in chloroform were treated in a vacuum flask, with 1 c.c. of bromine. The rise of temperature was only about 0·8° C. for dextrorotatory turpentine, 23°—24° for French turpentine, about 17° for German turpentine, 23° for rectified oil of turpentine, 13·6° for rosin oil, — 0·85° for ligroin, and 2·3° C. for petroleum. The method is thus valuable for distinguishing dextro- from lævo-rotatory products, and may be of assistance as a rapid method of detecting impurity.—W. H. P.

Linoxyn; Characters of ——. F. Fritz and C. Zymandl. Chem. Rev. Fett Ind., 1914, 21, 43—44.

The following values were obtained with samples of solid oxidised linseed oil :—

Description.	Consistence.	Sp. gr. compared with water at 4° C.	Iodine value (Wijs).	Ash.	Unoxidised fatty acids.	Oxidised fatty acids.	Water-soluble fatty acids.
				per cent.	per cent.	per cent.	per cent.

—C. A. M.

American colophony; Water-soluble rosin acids of ——. L. Paul. Chem. Rev. Fett Ind., 1914, **21**, 5—8, 36—39, 53—56, 78—80.

American colophony is composed of a portion insoluble in cold petroleum spirit but readily soluble in dilute sodium carbonate solution, and a portion soluble in petroleum spirit, which dissolves with difficulty in the alkaline solution. On treating the sodium carbonate solution with hydrochloric acid a rosin acid separates as a scum. The portion insoluble in sodium carbonate solution dissolves in water, but on the addition of hydrochloric acid forms an emulsion from which the rosin acid separates as a coagulated mass. This acid melts at 74° to 75° C., and is the main constituent (about 80 per cent.) of American colophony: acids of higher m. pt. are only present in small proportion. The amount of insoluble deposit obtained by treating colophony with petroleum spirit varied in one experiment from 18 to 36 per cent., according to the amount of large glassy particles in the sample. This was attributed to intramolecular decomposition of the rosin with the absorption of water, and the formation of a hydrate of the principal acid. The principal rosin acid absorbed water when exposed to the air for a long time and yielded gradually increasing amounts (2·4 to 12 per cent.) of the compound insoluble in petroleum spirit. Other acids were also formed by hydration, and these were present in varying quantities in the original colophony. The products of the distillation of colophony differed considerably from the corresponding fractions obtained by distillation with petroleum, the differences being attributed to the formation of hydration compounds of the main acid. The insolubility of the sodium salt of this acid in 5 per cent. sodium carbonate solution may be used as a test of the presence of the acid in other resins. The hydration of this acid is to be regarded as the cause of the disintegration of colophony into powder.—C. A. M.

Patents.

White-lead; Apparatus for making ——. R. A. Stewart, Los Angeles, Cal. U.S. Pat. 1,088,041, Feb. 24, 1914.

The fumes from lead ore, roasted in a furnace, are drawn, by means of a fan, through a supplementary roasting chamber, provided with baffle-plates, in which the fumes are roasted by means of burning jets of carbonaceous fuel and air, and thence into a collecting chamber in which the white lead is intercepted by filters, from which the white lead is continuously removed.—E. W. L.

Lampblack from hydrocarbons or hydrocarbon mixtures; Process for producing ——. K. Bosch. Ger. Pat. 270,199, Feb. 8, 1913.

Dry and very finely divided lampblack, free from mechanically combined hydrogen, is obtained by introducing the hydrocarbon (*e.g.*, acetylene) into the decomposition chamber through a rotating tube, to give it a circular motion.—T. F. B.

Ink. T. M. Price, Washington, D.C. U.S. Pat. 1,088,840, March 3, 1914.

The ink is composed of lanolin—or other fat, solid at 35° C. (95° F.)—50; glycerin, 10; carbon (or other colouring matter) 40 per cent., worked together into a plastic mass. —E. W. L.

Polishing composition. J. W. Aylsworth, East Orange, Assignor to Halogen Products Co., Glen Ridge, N.J. U.S. Pat. 1,090,440, March 17, 1914.

Chloronaphthalene or other higher halogen substitution compound of naphthalene is incorporated with a fusible soluble phenolic or cresolic resin melting at not less than 100° C. and a volatile solvent, such as acetylene-tetrachloride, or a mixture thereof with a rapidly drying solvent.—C. A. M.

Varnish and the like ; Method of and means for curing and drying articles coated with moist substances such as ——. W. J. Mellersh-Jackson, London. From Greeff Engineering and Manufacturing Co., Newark, N.J., U.S.A. Eng. Pat. 11,193, May 13, 1913.

THE articles are subjected to a current of warm moist air, under pressure, in a chamber with a restricted inlet and outlet. The air may be brought to the required temperature (125° to 126° F., 51·7°—52·2° C.) and humidity (35 to 45 per cent.), by being forced by a blower through an inner vessel surrounded by water heated by means of a steam coil.—C. A. M.

Infusible condensation product of metacresol and formaldehyde. Infusible condensation product. L. H. Baekeland, Yonkers, N.Y., Assignor to General Bakelite Co., New York. U.S. Pats. 1,088,677 and 1,088,678, March 3, 1914.

(1) THE product contains, as an essential constituent, a condensation product of formaldehyde and *m*-cresol, or this product together with a condensation product of formaldehyde and phenol, with or without a filling material, and containing corresponding condensation products of *o*- and *p*-cresol in minor proportions. (2) The product contains as essential constituents the condensation products of formaldehyde and *m*- and *p*-cresol respectively (the former in preponderating proportions) with or without a filling material ; or of the above condensation products together with the condensation product of formaldehyde and phenol (the *m*-cresol and phenol compounds in preponderating proportions), with or without a filling material. —E. W. L.

Plastic masses and method of producing the same. J. W. Aylsworth, East Orange, Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,090,439, March 17, 1914.

A FUSIBLE phenol resin is mixed with inert filling material and with sufficient anhydrous phenol and monochloronaphthalene (or organic fluid containing a condensable compound) to render the mass plastic at low temperatures, together with a hardening agent (*e.g.*, an anhydrous compound containing a methylene group) which will condense the phenol and phenol resin into a hard mass on heating the mixture.—C. A. M.

Resinous and other products ; Process of extracting —— from wood, with the simultaneous production of paper-pulp. Soc. Anon. Le Camphre. Fr. Pat. 463,879, Dec. 28, 1912.

RESINOUS woods are boiled under pressure with a solution of caustic soda containing a large proportion of sodium salts (*e.g.* carbonate, sulphate or a mixture of the two). The oil of turpentine leaving the autoclave is condensed. The residual lye containing alkali resinate is evaporated and decomposed by calcination into rosin oil and alkali, with the formation of methyl alcohol, acetone, tar, etc., as by-products.—C. A. M.

Paints, enamels, and the like ; Method of making ——. A. S. Ramage, Buffalo, U.S.A. Eng. Pat. 13,422, June 10, 1913. Under Int. Conv., Feb. 1, 1913.

SEE U.S. Pat. 1,084,361 of 1914 ; this J., 1914, 208. —T. F. B.

[Resinous] compositions of matter ; Process of manufacturing ——. L. Lilienfeld, Vienna. U.S. Pat. 1,090,730, March 17, 1914.

Derivatives of safranine dyestuffs. Fr. Pat. 463,357. *See* IV.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

Rubber ; Decomposition of —— by micro-organisms. N. L. Söhngen and J. G. Fol. Zentr. Bakt. u. Parasitenk., I. Abt., 1914, **40**, 87—98. Chem. Zentr., 1914, **1**, 1231—1232.

MANY bacteria and mould fungi will develop on rubber, in presence of sufficient moisture, at the cost of the protein, sugars, and resins : in some cases red, yellow, black or brown spots are produced, but the mechanical properties of the rubber are not notably affected. Two species of *Actinomyces*, *A. elastica* and *A. fuscus*, usually present in garden soil and canal water, are capable of attacking and assimilating the caoutchouc hydrocarbon. This action is due to the developing organisms, not to a soluble enzyme secreted by them, and hence on plantations the rubber should be dried as rapidly as possible, in order to prevent bacterial growth.—A. S.

Caoutchouc ; Synthetic —— from isoprene. G. Steimmig. Ber., 1914, **47**, 852—853.

IN reply to Harries (this J., 1914, 325), it is pointed out that if on treating the decomposition products of caoutchouc-ozonide with phenylhydrazine acetate and then adding mineral acid, solid phenylmethyldihydropyridazine is immediately formed, this is no proof that acetonylacetone was not present among the decomposition products. To recognise the presence of acetonylacetone it is necessary to distil the mineral acid solution with steam, in order to convert the phenylhydrazine compound into the volatile phenylaminodimethylpyrrole. The isoprene used in the author's previous experiments (this J., 1914, 267) was prepared from isopentane and carefully purified : its b. pt. was 33·5°—34° C. and sp. gr. 0·6785 at 18·5°/4° C. The statement that all caoutchouc-like substances hitherto obtained from isoprene consist of mixtures of polymerides of 1.5- and 1.6-dimethylcyclooctadiene-(1.5) is reaffirmed.—A. S.

Rubber in Namaqualand. Board of Trade J., April 2, 1914. [T.R.]

A COMPANY has been formed with a capital of £6,000 for the purpose of exploiting the *Euphorbia drageana*, which grows wild in the uplands of Namaqualand, and is stated to yield 17·6 per cent. of pure rubber and 70 per cent. of resin. The company holds a concession of some 220 square miles, containing about 6,000,000 bushes of this plant.

PATENTS.

Polymerisation processes and products obtained thereby [Manufacture of rubber-like substances]. E. H. Strange and H. J. W. Bliss, London. Eng. Pat. 3045, Feb. 5, 1913.

THE use of high pressures is claimed in polymerisation processes when the product has a considerably higher specific gravity than the initial material, *e.g.*, in the polymerisation of butadiene and its homologues to caoutchouc substances. The action of high pressure may be combined with that of other means of polymerisation. In order to produce an appreciable effect, it is usually necessary to employ pressures exceeding 500 lb. per sq. inch. In an example of the polymerisation of butadiene, the process is carried out under a pressure of 20 to 25 tons to the square inch, in the form of apparatus described by Hite (Amer. Chem. J., 1899, 80 ; see this J., 1899, 736).—T. F. B.

Rubber-bearing plants ; Process for facilitating the elimination from the bark of landolphia vines and other kinds of —— of the portions which are non-laticiferous. S. Goldreich and J. L. Palmer, London. Eng. Pat. 13,760, June 13, 1913.

THE outer portions of the bark are ground away without materially pressing it, by passing it between a pair of differentially geared fluted grinding rolls, the speed of one roll being about 20 per cent. greater than that of the other and afterwards removing the barren particles by sifting. The material is then pressed into sheets, flakes, etc., between even geared rolls and again sifted to remove any further barren particles.—E. W. L.

Rubber latex; Process of coagulation of ——. C. H. Boehringer Sohn. Fr. Pat. 464,192, Oct. 28, 1913. Under Int. Conv., Oct. 31, 1912.

Latex is coagulated by means of lactates of aluminium, more particularly the normal lactate. 250 c.c. of a 5 per cent. solution of aluminium lactate will coagulate 3000 grms. of latex in 8 mins.—E. W. L.

Gutta-percha; Manufacture of ——. R. B. Ransford, London. From Nederlandsche Gutta-Percha Maatschappij. The Hague, Holland. Eng. Pat. 20,118, Sept. 5, 1913.

The leaves and twigs of the trees are finely ground, mixed with water, stirred, and heated to 70° to 75° C. to extract the gutta-percha.—B. N.

India-rubber substitutes; Process for the preparation of ——. J. R. and M. E. McPhie, Newcastle-on-Tyne. Eng. Pat. 4214, Feb. 19, 1913.

An oil, fat, glyceride or fatty acid is treated with strong nitric acid, and the resulting yellow oil is well washed with boiling water, and purified by repeated solution in alkali and reprecipitation with acid until an elastic mass, unaffected by alkali solution, is obtained. This is washed with warm water and dried below 100° C.—E. W. L.

Imitation rubber with a basis of acetylcellulose, and various materials and fabrics made therefrom. Act.-Ges. für Anilin-Fabrikation. Fr. Pat. 463,622, Oct. 14, 1913. Under Int. Conv., Mar. 22, 1913.

Acetylcellulose is mixed with a substance of low volatility capable of conferring plasticity upon the mass, loading or colouring matters being added as desired. For example: 1 part of nitroacetylcellulose (see Fr. Pat. 449,253 of 1912; this J., 1913, 482) is digested with 2 parts of methyl phthalate. When the temperature reaches about 60° C. the mass swells up and agglutinates. The addition of a small quantity of a volatile solvent, such as acetone, hastens the swelling. The mass may be coloured black by the addition of an alcoholic solution of nigrosine. Or, 5 parts of acetylcellulose may be digested with 10 parts of triacetin and 1 part of amyl alcohol. The mass may be mixed with reclaimed rubber and 7 per cent. of sulphur and vulcanised by heating for 1 hr. at 135° C. It may also be dissolved in 2 parts of acetone and 3 parts of benzine added to the solution, which may then be employed for impregnating fabrics. Or the mass may be run into the form of a thin sheet at 60° C. and under a pressure of 50 to 150 kilos. per sq. cm., and applied to a fabric under pressure. The surface of the fabric should be first prepared with a dilute solution of 1 part of nitroacetylcellulose, 1 part of triacetin and 10 parts of tetrachloroethane or acetone, and dried.—E. W. L.

Rubber and like gums; Method and apparatus for extracting ——*from gum-containing plants.* F. Kempter, Stuttgart, Germany. Eng. Pat. 17,880, Aug. 5, 1913.

See Fr. Pat. 461,093 of 1913; this J., 1914, 93.—T. F. B.

Caoutchouc; Process for manufacturing synthetic ——. C. K. F. L. Gross, Christiania, Norway. U.S. Pat. 1,090,847, March 24, 1914.

See Fr. Pat. 459,987 of 1913; this J., 1913, 1164.—T. F. B.

Extracting fats, rubber, waxes, etc., by means of solvents. Fr. Pat. 463,178. *See* XII.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin; Composition of ——. *III.* L. F. Iljin. Ber., 1914, **47**, 985—993. (See also this J., 1909, 665, 1151; 1910, 504.)

By partial precipitation of a tannin solution with lead acetate, and extraction of the unprecipitated portion with ethyl acetate (Trimble, *The Tannins*, 1892, vol. I., 85), a product of higher rotatory power than the original tannin was obtained, whilst by decomposing the lead precipitate with hydrogen sulphide and extracting with ether, a product of lower rotatory power was obtained. By repeated fractionation in this way products of rotatory power $[a]_D$ = about +29° and +117° respectively, were obtained. By similar fractional precipitation with zinc acetate, the zinc compound being decomposed by the calculated quantity of dilute sulphuric acid, products having $[a]_D = +5{\cdot}16°$ and $+137{\cdot}85°$ respectively were obtained. The former was sparingly but the latter readily soluble in cold water. The product of higher rotatory power yielded gallic acid and dextrose on hydrolysis.—A. S.

Tannin; Constitution of ——. *XI.* A. Geake and M. Nierenstein. Ber., 1914, **47**, 891—898.

The formation of dextrose in the hydrolysis of tannin with acids (compare Fischer and Freudenberg, this J., 1912, 503, 1043) is confirmed. Nierenstein's earlier failure to detect dextrose as a component of the tannin molecule (this J., 1912, 652) was due to the use of alkali for effecting hydrolysis. The dextrose is not present in a free or loosely-combined form: the rotatory power of tannin is not diminished by the action of beer yeast, as stated by Biddle and Kelley (this J., 1912, 737), provided care be taken to prevent infection by moulds (compare Knudson, this J., 1913, 545). By partial hydrolysis (4 hours with 5 per cent. sulphuric acid) of carefully purified tannin, there were produced 2½—4 per cent. of a crystalline substance, not yet identified, which did not yield sugar on hydrolysis, 20—25 per cent. of gallic acid, and 60—70 per cent. of an amorphous substance of almost the same composition and properties as the original tannin, but differing from the latter and from the pentadigalloylglucose of Fischer and Freudenberg (*loc. cit.*) by its considerably higher rotatory power, especially in glacial acetic acid and in alcohol.—A. S.

Fat as a by-product in the manufacture of glue from hide trimmings. Dubovitz. *See* XII.

Patents.

Animal refuse; Thermo-chemical process and apparatus for transforming —— *into fat, flesh powder, gelatin, etc.* J. Margoles. Fr. Pat. 463,179, July 24, 1913.

Animal refuse, etc. is heated with steam under a pressure of 2 to 8 kilos. in autoclaves containing perforated cylinders in which agitators rotate. The decoction of nitrogenous substances, fat and condensation water is continuously drawn off into closed vessels, where the different constituents are separated, whilst the residual nitrogenous matter is dried *in vacuo* in a cylinder provided with beaters and heated by steam coming from the digester. —C. A. M.

Leather scrap; Manufacture of a solid and elastic mass from ——. G. Kraitschier and "Veto Company" Vertriebsges. für Schutzapparate gegen Feuer und Einbruch, G. m. b. H. Fr. Pat. 463,200, Sept. 13, 1913.

Finely divided leather scrap is bleached for 8 hours in a bath of chloride of lime, dried, washed in water, dried again, reduced to powder and mixed with an agglomerant either damp or with a small quantity of fatty material. The material is then moulded by hydraulic presses. The incombustibility may be increased by addition of borax, sulphuric acid or potassium silicate.—D. J. L.

Casein-glue; Process for preparing ——. A. and A. Bernstein. Ger. Pat. 270,200, Jan. 29, 1913.

Casein is treated with free resin acid or with resin containing a large percentage of free resin acid, in presence of hot water, and the mixture is brought to the condition of a colloidal solution by addition of alkali.—T. F. B.

Horn or leather; Manufacture of substances similar to —— from leather or leather scrap. P. P. Damgaard and M. P. Rasmussen. Fr. Pat. 463,596, Oct. 14, 1913.

Leather scrap is treated with alkali to remove tannin and then with a glue solution containing acetic acid after washing away excess of alkali. The mass is filter-pressed, allowed to stand for some time, when it becomes nearly black, and then hardened by means of formaldehyde vapour or solution.—D. J. L.

Leather; Process for the manufacture of artificial ——. L. Lilienfeld, Vienna. Eng. Pat. 28,210, Dec. 6, 1912. Under Int. Conv., April 6, 1912.

See Fr. Pat. 456,261 of 1913; this J., 1913, 953.—T. F. B.

Hides; Method of treating —— before tanning. C. C. Moore and W. Trantom, Lymm. U.S. Pat. 1,091,236, March 24, 1914.

See Eng. Pat. 18,890 of 1913; this J., 1914, 326.—T. F. B.

XVI.—SOILS; FERTILISERS.

Marshy land; Improvement of —— in Finland by addition of sand. A. Rindell. Finska. Moss Kulturforeningens Tidskrift, Helsingfors, 1913. Reprint 8 pp. Biedermann's Zentr., 1914, **43**, 157—159.

Experiments with oats extending over two years showed that loam is much superior to sand as an addition to unmanured marshy land. The addition of sand did not produce any improvement unless more than 400 cubic metres per hectare (5700 cb. ft. per acre) were added. If the land was otherwise provided with phosphates and potash, the difference in effect between sand and loam was not appreciable.—W. H. P.

Phosphoric acid in soils; Determination of ——. R. Hornberger. Landwirtsch. Versuchsst., 1913, **82**, 299—302. Biedermann's Zentr., 1914, **43**, 148—149.

In the analysis of soils the ammonium phosphomolybdate precipitate frequently does not dissolve completely in ammonia, a whitish residue being left. This consists mainly of hydrated titanium dioxide but it may contain as much as 3 mgrms. of phosphoric acid. The precipitate should therefore be fused with sodium carbonate and extracted with water. Sodium phosphate dissolves with the carbonate and the phosphate can be determined in the usual way in the solution. Acid sodium titanate remains undissolved.—W. H. P.

Soils; Presence of some benzene derivatives in ——. E. C. Shorey. J. Agric. Research, 1914, **1**, 357—363.

Eight different samples of a sandy soil from Florida at present devoted to orange culture were examined, the top soil and the subsoil separately. From one subsoil sample *benzoic acid* was isolated (2 grms. from 25 kilos. of soil); from several other samples, principally subsoils, *m-hydroxytoluic acid* (up to 10 grms. from 25 kilos.), and from four samples, *vanillin* (a few mgrms. from 25 kilos.); in all the samples evidence of the presence of small quantities of vanillin was obtained. It seems unlikely that the vanillin exists in the soil otherwise than as free vanillin, and it is concluded that in some of the soils examined, at least a portion of the two acids is present as free acid.—W. H. P.

Winter spraying with solutions of nitrate of soda. W. S. Ballard and W. H. Volck. J. Agric. Research, 1914, **1**, 437—444.

Experiments in 1912 showed that the blossom on Yellow Bellflower apples opened about a fortnight earlier when the trees were thoroughly sprayed with a solution containing sodium nitrate (1 lb. per gall.) and caustic potash (1 lb. per 7 galls.), early in February. The foliage was not stimulated so soon as the blossom, but the yield of fruit from the treated trees was five times as great as from a check row of untreated ones. A single tree receiving 50 lb. of sodium nitrate as root fertiliser gave no increased production. In 1913, although frost spoiled the setting of the crop, it was found that the stimulation of blossom was also produced by calcium nitrate and cyanamide but not by ammonium sulphate. Sulphate of potash had some effect, but superphosphate none. A weaker nitrate solution and nitrate in the absence of alkali were not so effective, but oxalic acid (1 lb. per 2½ galls.) had a similar effect to the alkali. Experiments on a large scale in 1913 gave favourable results with apples and pears, but not with stone fruit such as cherries.—W. H. P.

Sugar cane; Manurial experiments with ——. H. A. Tempany. Imp. Dept. Agric. for West Indies. Report on experiments conducted in Antigua and St. Kitts, 1912-13, 65—94.

The best results were secured when adequate dressings of pen manure and allied fertilisers were applied to fields destined to bear plant canes, while a light dressing of quick-acting nitrogenous manure at the rate of 40 lb. of nitrogen per acre, applied in the early stages of growth, was of benefit to ratoon canes. Applications of artificial manures to plant canes which had received an adequate dressing of pen manure were ineffective in producing further remunerative increases of yield, while the combination of phosphates and potash with nitrogen, and also the use of slow-acting nitrogenous manures was unproductive of profit in the case of ratoon canes. The average profits derived from the use of calcium nitrate were somewhat less than with sodium nitrate, but greater than with ammonium sulphate. The application of nitrolim (crude calcium cyanamide) was attended by financial loss. Small gains ensued from the application of molasses to ratoon canes, but not sufficient to prove profitable unless the value of exhausted molasses was very low.—L. J. de W.

Patents.

Plants, fields, sown seeds, crops, or the like; Chemical, electro-chemical, and electric treatment of ——. R. Mies, London. Eng. Pat. 11,997, May 22, 1913.

The soil is treated with solutions of phosphoric acid, copper and manganese salts, picric acid, sodium chloride, lime, and carbon bisulphide, and then subjected to the action of a current of electricity of 80,000 volts and about 30 milli-amperes, the electrodes being placed in the ground at a depth of about 25 cm. In the case of growing plants, one electrode may be attached to the stem, and the other placed in the soil around the roots; a current of electricity of about 20,000 volts and 25 milli-amperes is then applied at intervals. Various methods of inserting or placing the electrodes in the soil are described.—W. P. S.

Basic slag; Apparatus for removing iron from ——. F. Steinert and H. Stein. Ger. Pat. 268,500, Dec. 6 1912.

The slag is ground in a tube-mill, the discharge end o which is enclosed by a concentric conical screen with it wider end towards the front of the apparatus. The fin material passes through the screen into an outer conica drum tapering in the opposite direction, whilst the coarse portion, including particles of iron, is thrown out at th end of the screen, into a magnetic separator forming a extension of the outer drum and connected therewith b an insulating ring. The particles of iron are retaine whilst the slag travels down the conical drum, and mix with the finer material.—A. S.

XVII.—SUGARS; STARCHES; GUMS.

Slow carbonatation. Clarifying effect. Analysis of scums. H. Pellet. Bull. Assoc. Chim. Sucr., 1914, **31**, 554—563. (See also Stanek, this J., 1913, 1080.)

Slow carbonatation frequently causes difficult filtration in the cane, as well as in the beet factory; silicates gradually pass into solution from the lime and on cooling separate out and clog the pores of the press-cloths. Carbonatation diminishes the polarisation to the extent of about 0·1° V. per 100 c.c., the lime either eliminating the optically active non-sugars, or modifying their rotation. In determining the clarifying effect, trustworthy figures are not given by a comparison of the apparent purity values; and the real purity, which indicates a lower clarifying effect than the apparent, should always be used. The content of organic matter in the scum calculated from the real purity of the juice before and after carbonatation, agrees well with that determined by calcining the scum in a current of oxygen, account being taken of the small amount of carbon always remaining unconsumed. When the lime used contains much magnesia, the weight of the dried scum found will be greater than that calculated from the lime added and from the substances eliminated from the juice, the water of hydration of the magnesium compounds not being expelled at the usual temperature of desiccation, viz., 105°—110° C. Another source of error in determining the dry substance of scum is the presence of calcium hydroxide, which has escaped carbonatation. During desiccation this is gradually carbonated, and a correction should be made after determining the amount present by dissolving a portion of the scum in sugar solution, and titrating with standard acid, a blank experiment being made at the same time using water in place of sugar solution.—J. P. O.

Beet slice dryers; Explosions in ——. Albrecht. Deut. Zuckerind., 1914, **39**, 269.

In the case of a Büttner and Meyer apparatus explosions were traced to the accumulation of dust, but in that of a Petry and Hecking dryer the cause was not ascertained, though owing to insufficient draught and the chimney being placed in the side, and not in the middle of the plant, opportunity was given for the collection of combustible gases, principally carbon monoxide. For the avoidance of such accidents, Köhler recommends the use of a "cyclone" dust separator, and that when the dryer is not in use, banking of the fire should be avoided, the chimney shutter kept open, and the ventilator damper always closed.—J. P. O.

Sucrose determination; Source of error in the Clerget ——. V. Stanek. Z. Zuckerind. Böhm., 1914, **38**, 289—298. (See also Langguth, this J., 1914, 96.)

The Herzfeld constant for the half-normal solution read at 20° C. is stated to be 132·66 provided the reading of the inverted solution is made within 3 to 5 minutes after filling the observation tube. Since this condition cannot always be realised, it is suggested that the polarisations after inversion be made 15 to 30 minutes after filling, when the rotation will have become constant, and that the constant used be 132·95 (say 133·00).—L. J. de W.

Honeys; Examination of Belgian ——. R. Ledent. Bull. Soc. Chim. Belg., 1914, **28**, 73—77.

Nineteen samples of genuine honey contained from 19·81 to 21·13 per cent. of water and from 0·08 to 0·32 per cent. of ash. The volume of the precipitates obtained with Lund's tannin test (see this J., 1910, 105) varied from 1·0 to 1·8 c.c.; this test, and those described by Fiehe and by Jaegerschmidt (this J., 1908, 1127; 1909, 805), are recommended for the detection of added invert sugar in honey (see also this J., 1910, 1072).—W. P. S.

d-Glucosamine; Conversion of —— into d-mannose. J. C. Irvine and A. Hynd. Chem. Soc. Trans., 1914, **105**, 698—710.

Methylglucosamine was converted into benzylideneaminomethylglucoside hydrochloride by interaction with benzaldehyde. Condensation took place only in presence of hydrochloric acid, and the product was exceedingly readily hydrolysed. The amino group was eliminated by treating a solution of 1 mol. of the hydrochloride with 2½ mols. of sodium nitrite: nitrogen was vigorously evolved and after a short time the nitrogen-free product separated as a white solid. This proved to be benzylidenemannose, the yield being about 90 per cent. of theoretical; it was very readily hydrolysed to *d*-mannose. Glucosamine has now been converted into dextrose (Chem. Soc. Trans., 1911, **99**, 250; 1912, **101**, 1128) and into *d*-mannose. Optical inversion must accordingly have occurred in one of these transformations, most probably in the latter during the action of sodium nitrite on the benzylideneaminomethylglucoside hydrochloride.

—J. H. L.

Rice starch; The fractional liquefaction of ——. F. J. Warth and D. B. Darabsett. Mem. Dept. Agric. India, [Chem. series], 1914, **3**, 135—147.

Starches from different varieties of rice can be distinguished by fractional liquefaction at different temperatures. 1 grm. of the material, prepared in a state of fine division by digestion with 1 per cent. potassium hydroxide for 24 hours, is stirred with 70 c.c. of water, and maintained at the desired temperature for 1 hour. The starch liquefiable at that temperature is converted into a paste in which unaltered starch granules remain suspended. The cooled liquid is then treated for 2 hours with 10 c.c. of malt extract at 30° C., at which temperature no appreciable erosion of starch granules occurs. An aliquot portion of the filtered solution is hydrolysed with hydrochloric acid, the dextrose determined by Fehling's solution and a permanganate titration of the cuprous oxide, and the amount of starch liquefied at the given temperature calculated. Very characteristic curves are obtained for various rice starches by plotting percentage liquefaction against temperature.—G. F. M.

Adhesives; Analysis of soluble ——. [Detection of gum arabic in presence of dextrin.] G. Armani and I. Barboni. Annali Chim. Appl., 1914, **1**, 138—142.

The sample is distilled with 12 per cent. hydrochloric acid and the distillate treated with a solution of benzidine acetate: a yellow colouration is produced if dextrin or gum arabic is present. A 30 per cent. solution of potassium hydroxide is then added gradually till a precipitate is produced, and the latter is dissolved by gradual addition of acetic acid: a red colouration, with violet reflex, indicates the presence of gum arabic or similar soluble gum in the original material.—A. S.

XVIII.—FERMENTATION INDUSTRIES.

[Brewing sugars]. Detection of raw beet products in admixture with raw cane products. A. R. Ling. J. Inst. Brew., 1914, 20, 185—195.

Sucrose derived from sugar cane is entirely identical with the sucrose of the sugar beet. The nauseous secondary matters present in raw beet sugars, however, render them unsuited for the preparation of brewing "invert" sugar, whereas raw cane products are eminently suitable on account of their full and luscious flavour. Admixture of partially refined inverted beet products with cane products may be quite undetectable by aroma or flavour, but may lead to yeast weakness and fretty beers. The detection of such admixture by means of the high proportion of calcium salts in the ash of cane as compared with beet products, appears to be no longer possible since lime is used for the defecation of beet juices. The author suggests that a more useful means may be found in the content of albuminoids (nitrogenous matters other than nitrates or nitrites) which is usually much higher in beet than in cane products. Owing to the wide variations which are found in the nitrogen-content of low-grade cane sugars, however, it is impossible to fix rigid limits for the albuminoid-content of invert sugars prepared from cane products, so as to exclude those made from beet, but the author suggests the values 0·3, 0·5 and 0·75 per cent. for invert sugars of grades 1, 2 and 3 respectively. In cases where these limits are exceeded however, additional evidence (odour and flavour) should be adduced before pronouncing that a sample contains beet products. In a number of samples known to be made from beet products, the author found 1·16, 1·38, 1·39, 1·70 and 1·12 per cent. (No. 1 grade) and 2·21 and 2·29 per cent. (No. 2 grade). The nitrogenous matters present in beet, consist largely of betaine, and are in general of lower molecular weight than those of cane, so that in the manufacture of brewing sugars they are less completely removed by the char. Betaine is not assimilated by yeast and may possibly be somewhat toxic; its decomposition product trimethylamine, would certainly impart a very unpleasant odour and flavour to beer.—J. H. L.

Fermentation ; Does the enzyme-theory of —— require limitation? E. Buchner and S. Skraup. Ber., 1914, **47**, 853—870.

THE authors criticise adversely the hypothesis recently advanced by Rubner (*Die Ernahrungsphysiol. der Hefezelle bei alk. Gärung*, Rubner's Archiv. f. Physiol., Suppl. Bd., 1913, 1—369) according to which there occurs in the yeast cell not only an enzymatic decomposition of sugar, but also a decomposition due to vital process not differing from the enzymatic one in its chemical course.—J. H. L.

Reductions ; Phytochemical ——. I. Transformation of the nitro-group into the amino-group. C. Neuberg and E. Welde. Biochem. Zeits., 1914, **60**, 472—479.

NITROBENZENE, added to sugar solutions in course of fermentation by living yeast, is in part reduced to aniline. In one experiment 17·5 grms. of nitrobenzene were added to 5 litres of fermenting 10 per cent. sucrose solution. After 5 days, 10 grms. of unchanged nitrobenzene and 3·9 grms. of aniline were isolated from the fermented liquid. (Cp. Neuberg and Steenbock, this J., 1913, 803.) —J. H. L.

Malt worts and beers ; Temperature corrections to be applied to the specific gravities of ——. F. E. Day and S. L. Amos. J. Inst. Brew., 1914, **20**, 196—198

TABLE I. shows the corrections necessary to convert sp. gravities of malt mash worts, determined in a 50 c.c. bottle at temperatures other than 60° F. and compared with water at the same temperatures, into gravities at 60° F. The table applies only to worts of which the gravities lie between 1024 and 1031, and before the corrections are applied a set of weighings of water and malt extract should be made, in order to be certain that the bottle used is not abnormal as regards expansion with heat.

TABLE I.

Invertase ; Action of —— on sucrose in methyl and ethyl alcohols of different strengths. E. Bourquelot and M Bridel. J. Pharm. Chim., 1914, **9**, 321—327.

ONE grm. of sucrose in 100 c.c. of methyl alcohol of 10 t 40 per cent. was completely hydrolysed by invertase a 18°—20° C. in 3 to 19 days. The invertase was prepare from top fermentation yeast (0·2 grm. in each case) whic had been killed by contact with ethyl alcohol for 12 hours then drained and dried in air. The invert sugar wa determined by reduction since it was found that as th percentage of alcohols increased, the rotatory power lævulose decreased and that of dextrose increased. Wit a higher percentage of methyl alcohol than 40 per cen the invertase was destroyed. With ethyl alcohol t action was complete in solutions up to 40 per cent. strengt but beyond this the hydrolysis was incomplete owing the insolubility of the invertase, although after tv months in contact with 90 per cent. alcohol it was st active.—L. J. DE W.

XIXb.—WATER PURIFICATION; SANITATION.

Lead [in water]; A new, very sensitive reaction for ——. W. N. Iwanow. Chem.-Zeit., 1914, **38**, 450.

A 2 per cent. solution of sodium bisulphite, which should not be acid to methyl orange, can be used for detecting minute quantities of lead in water. The addition of an equal volume of the reagent produces a cloudiness, which, if the quantity of lead is very small (1 in 1,000,000), appears only after some minutes. The presence of copper, silver, nickel, iron, aluminium, magnesium and calcium does not influence the reaction, but barium or tin must not be present. The sensitiveness of the reaction is 1 : 20,000,000.—G. F. M.

Bacteria; The escape of —— into the atmosphere by the spraying of polluted water. L. Cavel. Comptes rend., 1914, **158**, 896—898.

The spraying devices used in some biological purifying stations for distributing polluted water over the bacteria beds are a source of considerable danger. Petri dishes containing sterilised gelatinised bouillon were exposed for specified times facing the direction of the wind, before and after passing over a bacteria bed. After 5 days whilst in most cases the dishes exposed to the air before passing over the bacteria bed remained sterile, those exposed to the air after passing over exhibited numerous colonies, amongst which could be identified some originating from the harmful bacteria normally found in sewage effluents.—G. F. M.

Patents.

[Water] Filter. H. Reisert, Cologne. U.S. Pat. 1,088,929, March 3, 1914.

A number of filter beds are arranged one above the other, conduits leading downward from each bed through the bed or beds beneath to a chamber which receives the filtered water from all the beds. The filtered water can be forced back by compressed air through any bed for cleaning purposes.—H. H.

Plague bacilli; Process for destroying ——. P. Brat. Ger. Pat. 270,076, Dec. 12, 1912.

The infected substances are treated with the vapours of acrolein or similar compounds, especially the distillates obtained by heating rape oil or other substances containing glycerol at temperatures above 350° C. Under these conditions, cultures of plague bacilli on agar were completely killed after 17 hours, whilst treatment with formaldehyde vapour for 24 hours was insufficient for the purpose.—T. F. B.

Sterilising liquids by means of ultra-violet rays; Apparatus for ——. V. Henri, A. Helbronner, and M. von Recklinghausen, Paris, Assignors to the R.U.V. Co., New York. U.S. Pat. 1,091,221, March 24, 1914.

Sterilising liquids by means of the ultra-violet rays; Apparatus for ——. T. Nogier, Lyons, France. U.S. Pat. 1,091,382, March 24, 1914.

See Eng. Pat. 9660 of 1911; this J., 1912, 356.—T. F. B.

Production, by means of the electric arc, of a gas with preservative properties. Fr. Pat. 463,728. *See* XI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Solanum angustifolium; Constituents of, and isolation of a new gluco-alkaloid from ——. F. Tutin and H. W. B. Clewer. Chem. Soc. Trans., 1914, **105**, 559—576.

30·92 kilos. of dried leaves, twigs and flowers of *Solanum angustifolium*, Ruiz et Pavon ("*Duraznillo Blanco*") from Peru were extracted with hot alcohol and the concentrated extract distilled with steam. Only a trace of essential oil was obtained. From the aqueous extract the following substances were isolated: quercetin, rutin (quercetin glucorhamnoside $C_{27}H_{30}O_{16},3H_2O$), *l*-asparagine and a new crystalline gluco-alkaloid, *solangustine*, $C_{32}H_{53}O_7N,H_2O$, m. pt. 235° C., which forms a crystalline sulphate insoluble in all solvents except boiling acetic acid. The hydrochloride and nitrate of solangustine are amorphous. On hydrolysis solangustine yields an amorphous alkaloid, *solangustidine*, $C_{27}H_{43}O_2N$, and 1 mol. of dextrose. The hydrochloride, hydrobromide, nitrate and sulphate of solangustidine are crystalline and insoluble in water. The aqueous extract also contained amorphous alkaloidal substance, lævulose and viscid amorphous products which yielded quercetin and 3.4-dihydroxycinnamic acid on treatment with alkalis. The portion of the alcoholic extract insoluble in water yielded triacontane, a phytosterol, $C_{27}H_{46}O$, a phytosterolglucoside, $C_{33}H_{56}O_6$, and a mixture of palmitic, stearic, cluytinic, cerotic, linolic and linolenic acids, as well as a higher fatty acid, probably melissic acid, solangustine, chlorophyll and resinous material. Neither the total extractives (equivalent to 3·5 grms. of the drug), solangustine (0·48 grm.) or the amorphous alkaloidal material had any physiological effect.—T. C.

Daviesia latifolia; Constituents of ——. F. B. Power and A. H. Salway. Chem. Soc. Trans. 1914, **105**, 767—778.

The ground leaves and stems of *Daviesia latifolia*, R.Br. collected in Victoria, were extracted with alcohol, and, after concentrating, the extract was distilled in steam. A small amount of essential oil with a pleasant smell was obtained, which after removing benzoic acid, distilled between 200° and 220° C. The following compounds were obtained from the portion of the alcoholic extract soluble in water: benzoic, salicylic, *p*-coumaric and fumaric acids, *dibenzoyl glucoxylose,* a quercetin glucoside and dextrose. Dibenzoylglucoxylose, $C_{25}H_{28}O_{12},H_2O$, m. pt. 147°—148° C., is the crystalline benzoyl derivative of a new disaccharide, *glucoxylose,* and possesses an extremely bitter taste. Glucoxylose, $C_{11}H_{20}O_{10}$, yields 1 mol. of dextrose and 1 mol. of xylose on hydrolysis. The portion of the alcoholic extract insoluble in water was chiefly resinous material and yielded myricyl alcohol, hentriacontane, a phytosterol, $C_{27}H_{46}O$, m. pt. 135°—136° C., benzoic, palmitic, stearic and linolic acids, and the same dibenzoylglucoxylose obtained from the aqueous extract. The bitterness of the drug is due to the crystalline dibenzoylglucoxylose, which belongs to a class of substances not hitherto observed to occur in nature.—T. C.

Tobacco resins; Chemistry of ——. J. von Degrazia. Fachliche Mitt. der oesterr. Tabakregie, 1913, 109—117. Chem. Zentr., 1914, **1**, 1196—1197.

Seven kilos. of "Turkish Gebitz," consisting of the waste from different Turkish smoking tobaccos, was extracted with warm water to remove tannin and alkaloid salts, dried, and extracted with hot alcohol. The cooled extract was filtered, the alcohol distilled off, and the residue washed with hot water to remove fatty acids. 250 grms. of resin were thus obtained and from it the following constituents were isolated. α-Tabakenic acid, a brittle, dark brown, odourless amorphous mass, sparingly soluble in alcohol when dry, soluble in methyl and amyl alcohols, chloroform, benzene, nitrobenzene, acetone, xylene, glycerin and oil of turpentine, very slightly soluble in ethyl and amyl acetates, insoluble in ether, petroleum spirit, and carbon bisulphide. β-Tabakenic acid, a dark green (probably due to chlorophyll) brittle mass, soluble in alcohol, chloroform, ether, nitrobenzene, amyl alcohol, ethyl acetate, and acetone, insoluble in carbon bisulphide, benzene, xylene, and petroleum spirit. γ-Tabakenic acid obtained as a viscous brown liquid of unpleasant odour; distinguished from the β-acid by not forming a lead salt; soluble in alcohol, ether, nitrobenzene, amyl alcohol, ethyl acetate, and acetone, slightly soluble in methyl alcohol, benzene, and xylene, insoluble in carbon bisulphide and petroleum spirit. Tobacco-resinol, $(C_6H_{10}O)_x$, present in the tobacco as an ester of the β- or γ-acid, forms white flocks of microscopic needles, m. pt. (uncorr. 219° C.), slightly soluble in the common organic solvents; m. pt. of acetyl-derivative, 154° C. Tobacco-resene, $C_{38}H_{64}O_2$, a reddish-brown viscous liquid, which is not attacked by fused alkalis; sp. gr. 0·941 at 18·7° C., n_D^{17} = 1·5169, miscible with most organic solvents, gives a turbid solution with petroleum spirit. The odour of the tobacco resin is due to the resene, which is present in larger quantity than the other constituents. About ½ grm. of essential oil, of pleasant odour, n_D = 1·4882, was also obtained.—A. S.

Phytin and phytic acid. G. Clarke Chem. Soc. Trans., 1914, **105**, 535—545. (See also this J., 1914, 371.)

The phytin was extracted with 4·5 per cent. acetic acid from the seeds of Indian field mustards from which the fat had been previously removed by extraction with petroleum. It was purified by taking advantage of the fact that it separates from a cold 8 per cent. acetic acid solution on boiling, and was obtained as a snow-white, amorphous powder containing carbon, hydrogen, phosphorus, calcium and magnesium. The free acid (phytic acid), prepared by way of the lead and copper salts, contained phosphoric acid in inorganic combination; the ammonium salt obtained from the sparingly soluble strychnine salt contained no phosphate in such combination. The composition of pure phytin corresponded to no calcium-magnesium salt of a simple acid ester of inositol and phosphoric acid, whereas the above strychinne salt, isolated from the mixture of acids, gave analytical results in agreement with salts of such acids. The author concludes that phytin is possibly a complex calcium-magnesium salt of an inositol-phosphoric acid and phosphoric acid, which yields a mixture of the two acids upon removal of the bases.—J. R.

Lophantus rugosus: The essential oil of ——. P. de Vilmorin and F. Levallois. Bull. Soc. Chim., 1914, **15**, 342—345.

The oil (yield about 1·5 grms. from 1 kilo. of the plant) was an amber coloured liquid, solidif. pt. below —15° C., soluble in all proportions in 95 per cent. alcohol, sp. gr. at 15°/4° C., 0·962 to 0·967; $[\alpha]_D$ = +4·89° to +6·19°, maximum saponif. value 3·7, after acetylation 7·4. Distillation at 10 mm. pressure gave the following fractions: 60°—63° C., 8 per cent.; 63°—90°, 2; 90°—94°, 86; residue, 4 per cent. The chief fraction (90°—92° C.) was probably methylchavicol, and was converted into anethol by boiling for 20 hours with alcoholic potassium hydroxide. The lower fractions consisted essentially of terpenes, and limonene was identified by its tetrabromide and nitrosochloride.—G. F. M.

Amber oil. A. Károly. Ber., 1914, **47**, 1016—1023.

Rectified amber oil containing a small proportion of acid and ester was fractionated by distillation. It consisted principally of terpenes boiling between 154° and 177° C., and sesquiterpenes boiling at 240°—260° C. The characters of the terpene fractions were: α_D = 0° to —1° 25′, sp. gr. 0·8473 to 0·8648 at 20° C., n_D = 1·4705 to 1·4818 at 20° C. Treatment with bromine gave a substance, $C_9H_9Br_3$, melting at 242° C., apparently identical with tribromohemimellitene. The terpene fraction was hydrated by heating with a mixture of dilute sulphuric acid and acetic acid to 60° C., when a small proportion of borneol was obtained. Some heptylic acid was produced by oxidising with permanganate at 0° C. Oxidation with nitric acid yielded terephthalic acid, 1.3-dimethylterephthalic acid, and an acid, $C_8H_7O_4N$, melting at 189°—190° C., possibly 2-nitro-*p*-toluic acid. The presence of dihydrohemimellitene and dihydroisodurene in the original oil was inferred.—F. Shdn.

Essential oils; Constituents of ——. *The sesquiterpene, β-gurjunene.* F. W. Semmler and K. E. Spornitz. Ber., 1914, **47**, 1029—1030.

To separate α- and β-gurjunene, the mixture was oxidised with a solution of permanganate in aqueous acetone solution, when the β-gurjunene was left unattacked. After purifying, this sesquiterpene boiled at 113·5°—114° C. at 7 mm., had α_D = +19°, sp. gr. 0·9329 at 20° C. and n_D = 1·50526. It was reduced by means of hydrogen in the presence of platinum black with the formation of dihydro-β-gurjunene, $C_{15}H_{26}$, which boiled at 115°—117° C. at 7 mm., had the sp. gr. 0·9239 at 20° C., n_D = 1·49490, and α_D = —37°. This tricyclic sesquiterpene is distinct from cedrene (this J., 1912, 660), for it yielded no characteristic products after ozonisation.—F. Shdn.

Fenchocamphorone; Total synthesis of —— *and its oxidation with Caro's acid.* G. Komppa. Ber., 1914, **47**, 933—936.

The lead salt of homo-apocamphoric acid (pinophanic acid) was distilled in a current of carbon dioxide when *rac.*-fenchocamphorone was produced (Ber., 1911, 44 1356). The semicarbazone, $C_{10}H_{17}N_3O$, melted at 220° C after crystallising from aqueous alcohol, and the keton regenerated therefrom melted at 110° C. *D-d*-fenchocamphorone prepared from *D-l*-fenchene gave apocampholide when oxidised with Caro's acid.—F. Shdn.

Fenchenes; Ozonisation of certain ——. G. Komppa and S. V. Hintikka. Ber., 1914, **47**, 936—938.

By the action of ozone upon an acetic acid solution of *D-l*-fenchene prepared from fenchylamine (see this J., 1908, 956), *D-d*-fenchocamphorone was produced together with an acid of m. pt. 70°—71° C. The same products were obtained by the ozonisation of *D-l*-fenchene prepared from *l*-fenchyl alcohol, and of *D-d*-fenchene. Wallach's formulæ for *D-l*-fenchene and *D-d*-fenchocamphorone are confirmed.—F. Shdn.

Vanillin. M. Lehmann. Chem.-Zeit., 1914, **38**, 388—389, 402—403.

The adulteration of vanillin is detected, and its amount determined, by estimations of the sintering-point, the melting-point as laid down in the fifth edition of the German Pharmacopæia, *i.e.*, the temperature at which the substance forms a continuous column of liquid containing solid particles, and the point of clear fusion. The author's method for determining these is described, and tables and curves showing the effect of the addition of from 1 to 50 per cent. of guaiacol carbonate, coumarin, heliotropin, benzoic acid, salicylic acid, acetylsalicylic acid, acetanilide, or phthalic anhydride, are given. Coumarin and heliotropin are recognised by their smell. Benzoic acid, salicylic acid, and acetylsalicylic acid with methyl alcohol and sulphuric acid give esters of characteristic smell. Acetanilide gives the isonitrile reaction, phthalic acid forms fluorescein, and sugar may be extracted with water and determined polarimetrically, or the vanillin-sugar mixture fused, when a blue fluorescence is observed if 3 per cent. or more of sugar is present.—O. E. M.

Volatile fatty acids; Solubility of certain metallic salts of —— in organic solvents. Application to the detection of these acids. H. Agulhon. Bull. Soc. Chim., 1913, **13**, 404—408.

The solubility of the coloured copper and iron salts of the lower fatty acids in organic solvents increases with the molecular weight of the acid, and this fact may be utilised for detecting the individual acids in mixtures. The solution of the acids is made neutral to phenolphthalein with caustic soda, and diluted to a concentration of 2 per cent. 2 c.c. are then treated with 1 c.c. of ether, and a 2 per cent. solution of copper sulphate added, drop by drop, with agitation, avoiding excess. If the ether is coloured blue, butyric, valeric, or a higher acid is indicated. Using benzene in place of ether, this is coloured blue if valeric or a higher acid be present, but not if only butyric acid be present. If the ether is not coloured, a similar test is made with ferric chloride solution in presence of ethyl acetate, which is coloured blue if propionic acid, but not if only acetic acid (or formic acid) be present. —A. S.

Catalysis of acids; Use of manganous oxide for the ——: preparation of fatty and aromatic ketones. P. Sabatier and A. Mailhe. Comptes rend., 1914, **158**, 830—835. (See also this J., 1913, 806.)

Manganous oxide is a still more suitable catalyst than iron oxide for the preparation of ketones from both fatty and aromatic acids, or mixtures of both. The vapours of the acid are passed over a layer of oxide 60 cm. long, heated to 400°—450° C. The oxide may be employed repeatedly, and as little carbonisation or polymerisation occurs the yields of the ketones are in most cases almost quantitative. The catalysis of a number of fatty acids is described, including the higher members of the series, and also isobutyric and isovaleric acids which, with other catalysts, had failed to give satisfactory yields of di-isopropyl- and di-isobutyl-ketones respectively. The synthesis of a number of mixed ketones such as phenyl isopropylketone (b. pt. 218° C.), phenyloctylketone (m. pt. 46° C.), and phenylbenzylketone (m. pt. 60° C.), is also described. A number of the latter were converted by reduction over nickel into hydrocarbons.—G. F. M.

Acid catalysts. Catalytic preparation of new ketones. Some applications of catalytic methods. A. Mailhe. Bull. Soc. Chim., 1914, **15**, 321—329.

Contrary to the statement of Senderens (this J., 1914, 160) other oxides than those of thorium and zirconium can be used with excellent results for the catalytic preparation of ketones from acids. Thus cadmium oxide and ferric oxide in many cases give satisfactory yields, and where they fail, as in the case of isobutyric and isovaleric acids (this J., 1913, 806) manganous oxide has given good results (see preceding abstract). Mixed ketones were prepared by directing the vapours of acids over a layer of ferric oxide maintained at 470°—480° C. A mixture of benzoic and phenylacetic acids yielded phenylbenzylketone (m. pt. 60° C.), benzoic and hydrocinnamic acids gave benzylacetophenone (m. pt. 72° C.), and benzoic acid and the toluic acids yielded the corresponding tolylbenzylketones. Acetic and *m*-aminobenzoic acids yielded *m*-aminoacetophenone (m. pt. 90° C.), and the first unsaturated ketone prepared catalytically, cinnamylmethylketone (m. pt. 41° C.), was obtained from cinnamic and acetic acids. Several ketones prepared directly by the catalysis of acids were converted into a variety of allied substances by catalytic methods. The hydrogenation of propione was effected by means of nickel at 150° C. The diethylcarbinol thus produced yielded, in presence of ammonia by catalysis over thoria at 350° C. the primary amine $(C_2H_5)_2CH.NH_2$, and in presence of hydrogen sulphide the mercaptan $(C_2H_5)_2CH.SH$. The hydrogenation of propioneoxime over nickel yielded a mixture of the primary and secondary amines, $(C_2H_5)_2CH.NH_2$, and $[(C_2H_5)_2CH]_2NH$. Butyrone, isobutyrone, and isovalerone yielded a similar series of transformation products.—G. F. M.

Compressed ammonia; Reactions with ——. (Reactions at high pressures, III.) A. Stähler. Ber., 1914, **47**, 909—913.

Using apparatus previously described (Ber. 1914, **47**, 580) the author investigated the action of ammonia at high pressures upon various organic compounds. To avoid corrosion of the autoclave by halogen derivatives its inner surface was silvered. Carbon tetrachloride, in the presence of a little copper and iodine, was converted into guanidine, along with traces of cyanogen, at 140 C. and pressures above 40 atmospheres. Ethyl chloride was completely decomposed in 12 hrs. at 220° C. and about 220 atmosphere pressure, the product containing about 80 per cent. of mono-, 15 per cent. of di- and 5 per cent. of tri-ethylamine. Ethylene dichloride very readily gave good yields of ethylenediamine. Chlorobenzene was not attacked even in presence of copper and iodine after 48 hrs. at 250° C. and 400 atmospheres, and bromobenzene only slightly in presence of ammonium and aluminium iodides. Tetrachloroethylene and hexachloroethane reacted readily with compressed ammonia, but the reaction product was black and apparently consisted of decomposition or polymerisation products together with carbon and ammonium chloride. Dichloroethylene was only slightly attacked. Pure ether was not attacked at 250° C. and 270 atmospheres. The action between aqueous ammonia and highly compressed carbon dioxide in the presence of pumice stone containing iron salts yields urea and hydrocyanic acid. Methyldichloramine also reacted with liquid ammonia at ordinary temperatures giving a product which reduced silver nitrate but not Fehling's solution and had a pronounced burning taste. This was possibly methyl di-imide CH_3N_2H, but owing to the explosive nature of the reaction product (possibly due to traces of nitrogen chloride) the author has not been able to establish its identity.—W. H. P.

m-Xylene, ethyl alcohol, water; The system ——. A. Holt and N. M. Bell. Chem. Soc. Trans., 1914, **95**, 633—639.

Alcohol is miscible in all proportions with *m*-xylene as with water, whilst water and *m*-xylene are immiscible.

The results of the examination of mixtures of the three substances at 0°, 19°, 41°, 63° and 98° C., are given in tables and two curve-diagrams, in one of which are shown isotherms obtained by plotting mols. of water added against mols. of alcohol in 100 mols. of alcohol plus xylene, whilst in the other—a triangular diagram—the results are plotted in vols. per cent. of the components. For alcohol contents up to about 75 per cent. by vol., the isotherms can be closely represented by the formula :—

$$\frac{\text{Percentage of alcohol}}{\sqrt{\text{Percentage of water}}} = \text{constant (K).}$$

The value of K varies with the temperature according to the expression $K_{tx}=K_{to}—0{\cdot}125\,tx$, where K_{tx} is, the constant at a temperature tx and K_{to} the value at 0° C. When water is added gradually to mixtures of xylene and alcohol containing from 75—25 per cent. of xylene by vol., the phase rich in xylene which first separates forms a lower layer, but as the amount of water is increased, a critical point is reached when the phases rich in xylene and alcohol respectively have the same specific gravity, and with still more water the phase rich in xylene forms an upper layer. With mixtures of xylene and alcohol in the proportions 75·11 to 24·89, 50·15 to 49·85, and 25·01 to 74·99 c.c., the xylene phase changed from bottom to top on addition of 4·39, 10·8, and 17·2 c.c. respectively of water.—A. S.

Propane ; Properties of pure ——. J. Timmermans. Bull. Soc. Chim. Belg., 1914, **28,** 71—72.

Propane was prepared by Lebeau's reaction (Comptes rend., 1905, **140**, 1042, 1264) :

$$2C_3H_7I+2NaNH_3=2NaI+C_3H_7.NH_2+C_3H_8+NH_3,$$

and by Frankland and Kolbe's method as modified by Stahrfoss : $2C_3H_7CN+2Na=NaCN+CNC_3H_6Na+C_3H_8$. After purification by suitable chemical treatment and by fractional distillation, it solidified at —187·8° C., and 1 litre of it at 0° C. and 760 mm. pressure weighed 2·0192 grms.—W. P. S.

Patents.

Hexa-amino-arsenobenzene, a triaminobenzenearsinic acid, and a diaminotetranitro-arsenobenzene ; Manufacture of ——. C. F. Boehringer und Söhne, Mannheim-Waldhof, Germany. Eng. Pat. 8137, April 7, 1913. Under Int. Conv., March 4, 1913.

The reduction of 4-amino-3.5-dinitrobenzene-1-arsinic acid to hexa-amino-arsenobenzene (see Eng. Pat. 7488 of 1913 ; this J., 1914, 41) can be effected in two or more stages. For example the first reduction may be effected by means of sodium hydrosulphite, when 3.4.5-triaminobenzene-1-arsinic acid is produced ; this may be further reduced by means of hypophosphorous acid to hexa-amino-arsenobenzene. Again, treatment of 4-amino-3.5-dinitrobenzene-1-arsinic acid with 50 per cent. phosphorous acid in presence of alcohol at about 40° C., results in the production of a diaminotetranitro-arsenobenzene, which can be converted into the hexa-amino-compound by means of stannous chloride and hydrochloric acid.—T. F. B.

Arseno compounds ; Process for preparing unsymmetrical ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,254, Sept. 25, 1912. Addition to Ger. Pat. 251,104.

A mixture of an organic arsinic acid or arsenoxide with an inorganic arsenic compound (arsenious or arsenic acids or their soluble salts or esters, arsenious chloride, etc.) is treated with a reducing agent. If more than one mol. of the inorganic arsenic compound is used, the products will contain more arsenic and be darker in colour. The unsymmetrical polyarseno compounds may be used for the treatment of animals infected with trypanosomes. —T. F. B.

Arseno-metal compounds ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pats. 270,253, 270,256, 270,257, and 270,258, Sept. 15, Oct. 5, 8, and 15, 1912. Additions to Ger. Pat. 268,220.

(1.) To prepare arseno-metal compounds other than those described in the principal patent (see this J., 1914, 218), the salts of other heavy metals, such as silver, mercury, or copper, either alone or in presence of a base-metal salt, are treated with 3.3′-diamino-4.4′-dihydroxyarsenobenzene. (2.) The polyarseno compounds, obtained by reduction of a mixture of an arsinic acid and an inorganic arseno-compound (see Ger. Pat. 270,254 ; preceding), are used in place of dihydroxydiaminoarsenobenzene. (3.) Any other arseno-compounds may be used. (4.) Instead of isolating the arseno compounds and combining them with the metallic salts, the requisite organic arsenic acid or arsenoxide is reduced in presence of the metallic salt.—T. F. B.

Arsenic-phosphorus and arsenic-antimony compounds ; Process for preparing metal-addition compounds of mixed ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,259, Oct. 19, 1912. Addition to Ger. Pat. 268,220 (see this J., 1914, 218).

The mixed organic arsenic-phosphorus or arsenic-antimony compounds are combined with metallic salts as described in the chief patent in connection with the arseno-compounds. The salts of silver, gold, copper, or metals of the platinum group may be used.—T. F. B.

Amino derivatives of primary aromatic antimony compounds ; Process for preparing ——. Chem. Fabr. von Heyden. Ger. Pat. 270,488, June 9, 1912.

Nitro derivatives of aromatic antimony compounds are treated with reducing agents or the acidylamino derivatives are saponified. The resulting amino compounds possess valuable therapeutic properties, owing to the antimony being more readily split off than the arsenic in the corresponding arseno compound. For example, *p*-acetaminophenylarsinic acid is saponified without further decomposition when boiled with sulphuric acid, but the corresponding antimony compound is completely decomposed.—T. F. B.

Organic arseno-compounds ; Process for preparing reduction products of ——. H. Bart. Ger. Pat. 270,568, Nov. 25, 1911.

Organic derivatives of arsenic acid or of arsenious acid are submitted to the action of an electric current at the cathode, in alkaline, neutral, or acid media. The reduction products are practically free from by-products, such as are formed during chemical reduction. No arsenic is split off during the process.—T.F. B.

3.3′-Diamino-4.4′-dihydroxyarsenobenzene-formaldehyde-sulphoxylates ; Process for rendering stable aqueous solutions of ——. R. Kaufmann and H. Vieth. Ger. Pat. 270,672, Oct. 26, 1912.

The solutions are rendered stable by addition of a sulphite. For dilute solutions, about 0·1 per cent. of sulphite is sufficient to preserve them for a short time, *e.g.*, when they are to be used for injection, but with stronger solutions more is required, up to half the weight of the arseno-compound.—T. F. B.

Pharmaceutical compounds [fatty acid derivatives containing arsenic and phosphorus] ; Manufacture of ——. F. Heinemann, Berlin. Eng. Pat. 10,379, May 2, 1913.

Derivatives of fatty acids of the acetylene series are converted into compounds containing arsenic or phosphorus, in the same manner as is described for treating the free acids in Eng. Pats. 18,732 of 1912 and 10,378 of 1913 (see this J., 1913, 102; 1914, 218). Another process consists in converting the fatty acids containing arsenic or phosphorus into their esters, anhydrides, anilides, or other derivatives, by known methods. The examples given in the specification relate to the preparation of such derivatives of halogenated behenolic or stearolic acids. —T. F. B.

Quinoline-4-carboxylic acids arylated in the 2-position; Manufacture of ——. Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. Eng. Pat. 15,481, July 4, 1913. Under Int. Conv., July 6, 1912.

THE 2-arylquinoline-4-carboxylic acids can be prepared by adding pyroracemic acid to a boiling alcoholic solution of a derivative or homologue of aniline and benzaldehyde, piperonal, vanillin, or other suitable aromatic aldehyde. For example, *p*-toluidine, benzaldehyde, and pyroracemic acid furnish 2-phenyl-6-methylquinoline-4-carboxylic acid, and when piperonal is used in place of benzaldehyde, 2-piperonyl-6-methylquinoline-4-carboxylic acid. The use of benzidine or its homologues in a similar manner gives rise to the corresponding diquinolyl derivatives. 6-Methyl-2 (4′-hydroxy-3′-methoxyphenyl)-quinoline-4-carboxylic acid, m. pt. 217°—219° C., obtained from *p*-toluidine, vanillin, and pyroracemic acid, is claimed as a new product.—T. F. B.

Antipyrylquinoline-4-carboxylic acid; Process for preparing 2- or 3- ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,487, Nov. 28, 1912.

ISATIN is condensed with 1-phenyl-2·3-dimethyl-4-aceto-5-pyrazolone or its homologues in alkaline solution. The products may be used in medicine.—T. F. B.

Tetrahydro-isoquinoline derivatives; Process for preparing ——. H. Decker. Ger. Pat. 270,859, Oct. 15, 1911.

THE base of the composition, $C_{10}H_{11}NO_2$, obtained from the condensation product of homopiperonylamine and formaldehyde (see Ger. Pat. 257,138; this J., 1913, 507), is treated with a methylating agent. One methyl group is thus introduced, probably attaching itself to the nitrogen. Oxidation of the salts of the methyl compound results in the formation of hydrastinine salts.—T. F. B.

Carbamic acid ester of a-dichlorhydrin; Manufacture of ——. B. Beckmann and Dr. Bruno Beckmann, Chem. Fabrik G. m. b. H., Berlin. Eng. Pat. 25,971, Nov. 12, 1913.

THE carbamic ester of a-dichlorhydrin is obtained by the action of carbamic acid chloride on a-dichlorhydrin; it forms colourless needles, of m. pt. 82°—83° C., and possesses strong narcotic properties.—T. F. B.

Camphor from pinene hydrochloride, hydrobromide, or hydriodide, or from an oily mixture containing same; Process for the commercial synthesis of ——. M. Hoenicke and H. A. Berens, London. Eng. Pat. 27,317, Nov. 27, 1913.

PINENE hydrohalogenides, or oily mixtures containing them, can be completely dehalogenised by treatment with nitric acid or its salts, at all concentrations; the reaction is facilitated by the presence of certain catalysts, such as metals, metallic oxides, chlorides, etc. The dehalogenation can also be effected by means of a mixture of nitric acid or a nitrate with chromic acid. *Example:* A mixture of 172 parts of pinene hydrochloride, 200 parts of sodium nitrate, and 100 parts of water is heated, with constant stirring, for 5 to 15 hours at 100°—120° C. The resulting camphor nitrate is separated and treated with water to isolate the camphor, which is heated under pressure with 5 per cent. caustic soda solution to remove any acid which remains. The aqueous solution containing nitric acid is concentrated and utilised for a fresh treatment of pinene hydrochloride.—T. F. B.

Bromodiethylacetyl isocyanate. F. Hefti, Altstetten, Switzerland, Assignor to Farbenfabr. vorm. F. Bayer und Co. U.S. Pat. 1,086,294, Feb. 3, 1914.

BROMODIETHYLACETYL isocyanate is a limpid oil, of b. pt. 110°—114° C. under a pressure of 70 mm.; it is soluble in petroleum spirit and benzene. It can be obtained by treating bromodiethylacetyl bromide or chloride with a silver or mercury salt of isocyanic acid. When treated with ammonia it is converted into bromodiethylacetylurea. —T. F. B.

Acetylsalicylic acid; Process for making salts of ——. O. Gerngross and H. Kast. Fr. Pat. 464,081, Oct. 11, 1913. Under Int. Conv., Oct. 11 and 31 and Nov. 7, 1912.

A SUITABLE metallic compound is added slowly, with constant stirring, to an aqueous solution or suspension of acetylsalicylic acid. Metallic oxides, hydroxides, carbonates, bicarbonates, and silicates may be used for the purpose. When it is desired to use the salts of metals with halogen acids or with oxyacids of sulphur, phosphorus, or nitrogen, the reaction must be carried out in presence of an alkali. The resulting salts may be separated from their solutions by evaporation *in vacuo*, or by precipitation with another salt or with acetone or other organic precipitant. In preparing the acetylsalicylates of alkali or alkaline-earth metals, or of magnesium, it is advisable to use a silicate, albuminate, or saccharate to protect the salt against the action of the base employed. The above process is applicable to the preparation of all metallic acetylsalicylates, including those of the heavy metals. —T. F. B.

Sodium acetylsalicylate; Process for preparing ——. J. A. Wülfing. Ger. Pat. 270,326, Feb. 26, 1913.

DRY, finely powdered acetylsalicylic acid is treated with the equivalent quantity of anhydrous sodium carbonate in presence of acetic ester. The reaction is quantitative. —T. F. B.

Oxalates; Process for preparing —— by heating the corresponding formates. Chem. Fabr. Grünau, Landshoff und Meyer A.-G., E. Franke, and W. Kirchner. Ger. Pat. 269,833, Feb. 18, 1912.

FORMATES are converted rapidly and almost quantitatively into the corresponding oxalates by heating them in an apparatus maintained at a temperature between 385° and 400° C.—T. F. B.

Trimethylamine; Process for preparing ——. K. H. Schmitz. Ger. Pat. 270,260, June 3, 1913.

A MIXTURE of a dry ammonium salt with dry trioxymethylene or paraformaldehyde is heated to a high temperature for a short time in an open vessel, preferably provided with a reflux condenser. The mass melts to a homogeneous liquid, and carbon dioxide is evolved; the reaction is complete in one to two hours at a temperature of 120°—170° C.—T. F. B.

Hexamethylenetetramine-methyl thiocyanate; Process for preparing ——. K. H. Schmitz. Ger. Pat. 270,486, June 27, 1913. Addition to Ger. Pat. 266,788 (see this J., 1914, 43).

A SOLUTION of formaldehyde and ammonia or of hexamethylenetetramine is treated with the methylamine salt or the ammonium salt of an inorganic or organic acid, or a solution of a salt of hexamethylenetetramine is heated, with or without addition of formaldehyde; in either case a soluble thiocyanate is added, whereupon hexamethylenetetramine-methyl thiocyanate is separated. Another process consists in treating a solution of formaldehyde and ammonia or of hexamethylenetetramine with hydrothiocyanic acid or its ammonium or methylamine salt, or a solution of hexamethylenetetramine thiocyanate is heated, with or without addition of formaldehyde. In either of the above processes the formaldehyde may be replaced by one of its polymerides.—T. F. B.

Chlorination ; Process and apparatus for ——. E. C. R. Marks, London. From E. I. du Pont de Nemours Powder Co., Wilmington, Del., U.S.A. Eng. Pat. 879, Jan. 11, 1913.

See Fr. Pat. 453,406 of 1913 ; this J., 1913, 767.—T. F. B.

Acetaldehyde from acetylene ; Process for the manufacture of ——. Consortium f. Elektrochem. Industrie, G.m.b.H., Nuremberg, Germany. Eng. Pat. 16,848, July 22, 1913. Under Int. Conv., July 27, 1912.

See Fr. Pat. 460,553 of 1913 ; this J., 1914, 42.—T. F. B.

Methylhexamethylenetetramine ; Process for the manufacture of sulphocyanide of ——. K. H. Schmitz, Breslau, Germany. Eng. Pat. 30,047, Dec. 31, 1913. Under Int. Conv., Feb. 3, 1913.

See Ger. Pat. 266,788 of 1913 ; this J., 1914, 43.—T. F. B.

Terpene hydrocarbons ; Producing unsaturated ——. E. Bergs, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,091,276, March 24, 1914.

See Fr. Pat. 434,285 of 1911 ; this J., 1912, 257.—T. F. B.

Medicated fibrous substances. Eng. Pat. 7650. *See* V.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic positives ; The production of direct ——. G. A. Perley, T. J. Twomey, and H. A. Robinson. J. Phys. Chem., 1914, **18**, 185—212.

The experiments described previously (this J., 1912, 902) were extended, the quinol being replaced by metol, pyrogallol, ortol, eikonogen, and amidol, and the thiourea by some of its substitution products. The developing agent influences the colour of the positive, but its chief function seems to be to reduce slightly the latent image in order to create a greater difference in the form of the silver halide in the exposed and unexposed parts of the plate. Allylthiourea and ethylthiourea proved to be superior to tetrathiourea-ammonium bromide and thiourea itself in the production of good positives. Excellent results were obtained by using allylthiourea in conjunction with quinol or eikonogen, or ethylthiourea with metol or eikonogen. A formula which gave excellent red to reddish-brown positives was :—metol, 0·032 grm. ; ethylthiourea, 0·0037 grm. ; sodium carbonate, 0·1 grm. ; sodium sulphate, 0·234 grm ; water, 9·3 grms. To avoid the excessive production of a negative, it is necessary to maintain a fairly constant ratio between the exposure and concentration of the constituents of the developer. Sodium sulphite is not essential to the production of positives by this method, but its restraining action improves the quality of the deposit. Sodium carbonate may be replaced by sodium hydroxide in the allylthiourea-quinol developer. The production of positives by developers containing thiourea compounds is attributed to the fact that the unexposed silver complex in the emulsion is much more soluble than the exposed portion. Hence the most efficient substance for the production of positives will be that which exhibits the greatest difference in solvent action towards the unexposed and exposed portions. Support for the above theory was obtained from the fact that positives of fair quality were obtained with the use of metol developers containing ammonia, methylamine, or ethylamine.—T. F. B.

Patents.

Toning photographic prints ; Method of ——. H. M. Ward, Leicester. Eng. Pat. 6026, March 11, 1913. Addition to Eng. Pat. 8002, April 3, 1912 (see this J., 1913, 550).

A silver print is "sulphided" in the usual manner and then toned in a copper toning bath to which is added a suitable silver solvent, especially a thiocyanate, a persulphate, or chromic acid. An alternative method is to tone the silver print with a copper toning bath and subsequently treat the image with an acidified sulphiding solution.—T. F. B.

Photographic developers. A. G. Bloxam, London. From Act.-Ges. f. Anilinfabr., Treptow, Germany. Eng. Pat. 18,095, Aug. 8, 1913.

4-Hydroxyphenylalkylglycines, of the formula $HO.C_6H_4.N(alkyl)CH_2.COOH$, or their derivatives are powerful photographic developers, which yield clear images ; they may be used in the form of alkaline solutions, preferably containing a preservative. In speed of development they stand between methyl-*p*-aminophenol and *p*-hydroxyphenylglycine. They are prepared by condensing a *p*-alkylaminophenol with a halogen derivative of acetic acid.—T. F. B.

Photographic reproducing processes ; Screens for use in ——. L. Böhm. Eng. Pat. 24,482, Oct. 28, 1913.

The screen apertures consist of irregular polygons of approximately equal area, irregularly distributed over the screen plate, and separated from one another by lines having the same thickness and intensity throughout the screen.—T. F. B.

Photography of colours ; Processes of ——. E. C. G. Caille. Fr. Pat. 463,062, Dec. 7, 1912.

The object to be reproduced is photographed on a panchromatic plate through a selective screen composed of points, lines, etc., of orange-red, green, and violet-blue. This negative, after development and fixation, is then used for the three successive printings on a sensitive support, through subtractive screens so chosen that only one colour is printed at a time. The support is prepared from paper rendered waterproof, for example by coating it with powdered zinc white mixed with a suitable oil varnish, and then provided with a gelatinobromide emulsion. The blue print is made first, the colour being produced by successive treatments with solutions of ferricyanide and ferric chloride ; the support is then re-sensitised by means of bichromate, and the yellow print is made, using solutions of iodine in potassium iodide, tartar emetic, and mercuric chloride. Finally, the red print is produced in the support, after a second re-sensitisation, using any suitable red dyestuff to produce the colour.—T. F. B.

Colour photography ; Processes of ——. E. C. G. Caille. First Addition, dated Dec. 9, 1912, to Fr. Pat. 463,062, Dec. 7, 1912 (see preceding abstract).

The methods of colouration described in the principal patent may be applied in the process in which the colour selection is effected by means of three separate colour screen filters. When the red image is to be printed by means of fatty ink, it is produced in the form of a discontinuous image, *e.g.*, as points or small squares, so as to leave between the coloured surfaces sufficient emulsion to be treated subsequently to produce the blue and yellow images by superposition.—T. F. B.

Photographs in colours; Process for producing ——. The Hess-Ives Co. Fr. Pat. 463,737, July 11, 1913. Under Int. Conv., July 12, 1912.

In the production of colour prints by transferring a coloured image from one support on to another, it is proposed to press together the two dry supports very strongly, with a thin layer of "separating liquid," such as 10 per cent. acetic acid, between them. The support to receive the coloured image is covered with hardened gelatin and is mordanted. The colours used are such as have no specific affinity for gelatin, but which form insoluble lakes with the mordant; thus, alizarin colours may be used in conjunction with an alum mordant. The dyebath used to colour the intermediate support, contains a salt such as potassium citrate which retards the absorption of the dyestuff by the gelatin; it is advisable to use a slightly acid dyebath containing a relatively large quantity of the dyestuff. If the colour of the prints is too intense, it may be reduced by a subsequent treatment with dilute acetic acid or other acid. The several colour prints are finally combined to form the finished photograph.—T. F. B.

Polychrome screen [for photography] and process of making the same. R. Ruth and A. Schuller, Oude-God, Belgium. U.S. Pat. 1,091,443, March 24, 1914.

See Fr. Pat. 449,080 of 1912; this J., 1913, 508.—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Heat test as applied to explosives; First report to the Home Office of the Departmental Committee [appointed April 21, 1909] on the ——. (See also under Books Received.)

The report deals with the best means of standardising, with greater accuracy than at present, the apparatus and materials employed in the Abel heat test. The following are some of the chief alterations proposed by the committee. A copper heat test bath is to be provided with a constant level apparatus, with seven holes in the lid at equal intervals from each other and equidistant from the centre, one of the holes being for the thermometer. A cage of two crossed wires is fixed to the underside of each test-tube hole, and unoccupied holes are covered with small discs of copper. The French chalk used for incorporating with gelatinous explosives should not absorb more than 0·5 per cent. of moisture under certain defined conditions, and 50 c.c. should weigh 23·5 ± 1·0 grms. A Wedgwood mortar and pestle are recommended for the incorporation of gelatinous explosives. Specified times are suggested for the incorporation of blasting gelatin (1½ mins.), gelatin-dynamite (1), and gelignite (½ min.) with French chalk. The new mill recommended for grinding cordite can be readily cleaned and the cutting edges can be accurately adjusted and easily repaired. A new design has been adopted for the water oven for drying guncotton, etc., so as to allow a current of air to pass over the sample, and aluminium trays are recommended in place of paper trays. Detailed directions are given for the preparation of nitrocellulose pulp for heat testing. After preliminary pressing the sample is rubbed through a sieve on to an aluminium tray, and, after drying, should be sifted in the nest of sieves as used for ground cordite. The same paper should be employed for filtering operations in connection with the heat test as that used n the preparation of heat test paper. The chemical contitution of the paper and its physical properties, such as hickness, weight, texture, surface, and length of fibre nfluence the result when the paper is sensitised for heat est purposes. Several samples of paper were specially repared, but, with cordite, did not give results conordant with those given by Waltham Abbey batch 8 hich was adopted as a standard. It is not sufficient merely to specify a filter paper, and the method of prearation of a heat-test paper from it. It is essential that the sensitiveness of the finished test paper be verified by a test. At present, batches of heat test papers are tested by the Chief Inspector, Woolwich, for acceptance into the service, by means of a selected sample of guncotton and in comparison with a standard heat test paper. This is not entirely satisfactory, because of the possible variations in both the guncotton and the standard heat test paper used as a control, and the committee recommend the introduction of a test in which the heat test paper to be standardised is exposed to nitrogen peroxide, under standard conditions. This "diffusion test" should be employed concurrently with the standard test. Standard tint papers should be prepared by using a permanent pigment. As light has the effect of reducing the time of the heat test, and as this effect is considerably more marked in the case of cordite than in other explosives, the exposed portion of the heat test tube should be covered with a ventilated cap of black paper. The heat test tubes should be of the best quality soda lime glass, free from lead and without streaks, and should, after heating for 3 hours at a steam pressure of 50 lb. per sq. in. show no more cloudiness than a standard sample so treated.—G. W.McD.

Hexanitroethane. W. Will. Ber., 1914, 47, 961—965.

Hexanitroethane is prepared by nitrating potassium nitroethane with nitric and sulphuric acids. It forms colourless crystals, smelling somewhat like camphor, which melt with decomposition at 142° C., are insoluble in water and nitrating acids, soluble in the usual organic solvents, and give an acid reaction with litmus. It yields unstable red or yellow addition-products with naphthalene, benzene, and toluene, red compounds with phenols, and an explosive compound with o-nitroaniline; it oxidises quinol to quinhydrone, and reacts with acetone, diphenylamine, and dimethylphenylurea. It is much less volatile than tetranitromethane, and hence may be used in explosives; at 75° C. it evolves red fumes in 30 mins. at 50° C. in 20 hours. In the Trauzl block it shows a net expansion of 180 c.c., is very insensitive, and with organic substances rich in hydrogen gives powerful explosives.—O. E. M.

XXIII.—ANALYTICAL PROCESSES.

Picric acid; The use of —— in standardising solutions, and the iodometric determination of acids. A. Sander. Z. angew. Chem., 1914, 27, 192—194.

Picric acid is recommended as a standard substance for iodometry. It is not hygroscopic and gives a very sharp end-point without the addition of an indicator. The following equations illustrate the interactions involved:—

$$6C_6H_2(NO_2)_3OH\text{(or 6HCl, etc.)} + 5KI + KIO_3 =$$

$6C_6H_2(NO_2)_3OK$(or 6KCl, etc.) $+ 3I_2 + 3H_2O$. Iodine is estimated by thiosulphate solution standardised by the picric acid (*N*/25 or *N*/100). The iodide-iodate solution should contain 40 grms. of potassium iodide and 10 grms.

of iodate per litre. It is very stable, but becomes yellow on prolonged exposure to light; sodium thiosulphate is then added until the colour disappears. Many coloured solutions of acids—and bases—may be analysed iodometrically if starch solution be added towards the end of the titration of the iodine. (See also following abstract.) —J. L. F.

Sulphurous acid in the presence of thiosulphate and also in the presence of sulphuric acid; Determination of free ——. A. Sander. Z. angew. Chem., 1914, **27**, 194—195.

The total sulphurous acid and thiosulphate are determined by titration with iodine, and then the sulphuric acid produced by oxidation of the sulphurous acid is determined by adding excess of iodide-iodate (see preceding abstract), and titrating the liberated iodine with sodium thiosulphate, thus :—

$$3H_2SO_4+KIO_3+5KI=3K_2SO_4+3I_2+3H_2O.$$

A mixture of sulphurous and sulphuric acids may be analysed in a similar manner, the former being oxidised by iodine, and the total sulphuric acid then present determined with iodide-iodate solution. Bisulphates behave in an analogous manner.—J. L. F.

Arsenite solutions; Determination of the titration value of ——. E. Deiss. Chem.-Zeit., 1914, **38**, 413—415.

The use of volumetric solutions of iodine for the standardisation of arsenite solutions may lead to erroneous results owing to the presence of iodate, which in the standardisation of the iodine by thiosulphate in acid solution yields its total iodine content as free iodine, but, in the subsequent titration of the alkaline arsenic solution, is entirely unchanged. The measured volume of iodine solution should therefore always be previously acidified with hydrochloric acid to decompose iodate, before adding sodium bicarbonate and titrating with the arsenite solution. In preference to this method the iodometric standardisation with the help of permanganate is recommended. A measured volume of standard permanganate is run into acidified potassium iodide solution, and the liberated iodine, after the addition of bicarbonate, titrated with the arsenic solution in the usual way.—G. F. M.

Arsenic; Determination of traces of —— *of the order of a thousandth of a milligram.* L. Moreau and E. Vinet. Comptes rend., 1914, **158**, 869—871.

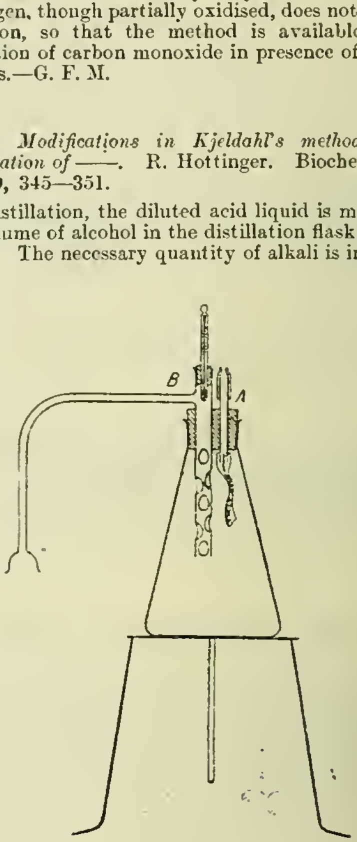
The method is based upon the deposition of a mirror of silver by the action of the hydrogen arsenide upon a solution of silver nitrate contained in a narrow glass tube bent twice at right angles, and comparing the mirrors obtained with standard mirrors. The arsenic hydride is generated in a small U-tube, containing 0·5 grm. of platinised zinc and dilute sulphuric acid. One limb of the U-tube is connected with the above-mentioned glass tube and the other with a dropping funnel containing the solution under test, and with a hydrogen generating apparatus through a second U-tube containing silver nitrate solution; the current of hydrogen is regulated to give 15 to 20 bubbles per minute in the mirror tube. By this method 0·001 mgrm. can easily be detected and estimated, but care must be taken not to use more than the specified quantity of the "purified" reagents.—G. F. M.

Carbon monoxide; Determination of —— *by means of yellow mercuric oxide.* L. Moser and O. Schmid. Z. anal. Chem., 1914, **53**, 217—233.

Carbon monoxide can be oxidised quantitatively by slowly passing it over about 20 grms. of yellow mercuric oxide contained in a U-tube, and maintained at 100° C. in a water-bath, and the resulting carbon dioxide absorbed in standardised baryta water. The mercuric oxide must be precipitated and dried at a low temperature, and protected from the prolonged action of light; oxide precipitated in hot solutions, or the red oxide, is inactive. About 45 mins. is required for the combustion of 100 c.c. of gas. Methane is unacted on by the yellow oxide at 100°C. and hydrogen, though partially oxidised, does not influence the titration, so that the method is available for the determination of carbon monoxide in presence of either of these gases.—G. F. M.

Nitrogen; Modifications in Kjeldahl's method for the determination of ——. R. Hottinger. Biochem. Zeits., 1914, **60**, 345—351.

Before distillation, the diluted acid liquid is mixed with half its volume of alcohol in the distillation flask shown in the figure. The necessary quantity of alkali is introduced through the tube, A, to the lower end of which is attached a lip-valve made by joining the long edges of two strips of india-rubber, 1·5 by 7 cm., by means of rubber solution and lightly vulcanising them with a dilute solution of sulphur chloride in carbon bisulphide. The dephlegmator is entirely within the flask, and consists of a portion of the tube, B, in which a number of recesses, disposed helically at intervals of 120°, have been made by suction of the tube after it has been closed at one end and softened at the respective points by means of a flame. The distillation of the ammonia is complete when the thermometer registers 99° or 100° C. The lip-valve prevents acid from being sucked into the flask through the tube, B. The advantages claimed are increased accuracy, and a great shortening of the time occupied by the distillation. —J. H. L.



Albumin; Colorimetric determination of ——. E. Riegler. Z. anal. Chem., 1914, **53**, 242—245.

The violet colouration produced by dissolving copper oxide in alkaline solutions of albumin, may serve as the basis of a colorimetric method. 10 c.c. of the solution to which 5 c.c. of 5 per cent. β-naphthalenesulphonic aci have been added, are centrifuged, and the clear solutio decanted from the precipitated albumin, which, with th addition of 4 drops of 20 per cent. copper sulphate solution is then dissolved in sufficient 3 per cent. sodium hydroxid to make 10 c.c. After shaking and once more centri fuging, the clear violet solution is compared with a 0·5 pe cent. solution of albumin which has been treated in th same way. Peptone, globulin, casein and other protein may be determined in an analogous way, using th appropriate comparison solution.—G. F. M.

XXIV.—MISCELLANEOUS ABSTRACTS.

High vacua; Production of —— by means of finely divided copper. T. R. Merton. Chem. Soc. Trans., 1914, **105**, 645—646.

Commercial "precipitated copper" absorbs gases—with the apparent exception of helium—with great readiness after being heated to about 250° C. under reduced pressure. Two or three grams of copper will exhaust a small vacuum tube to a non-conducting vacuum. The gases absorbed are evolved again on reheating.—J. L. F.

Gold surface; Electrical condition of a —— during the absorption of gases and their catalytic combustion. H. Hartley. Roy. Soc. Proc., 1914, **90**, 61—68.

Gold acquires a negative charge during catalytic combustion of gases on its surface. The electrical effect probably precedes the actual combustion and is primarily due to occlusion. The metal can be charged negatively by occlusion of hydrogen or carbon monoxide, and positively by the occlusion of oxygen. The charge is probably due to the gas leaving (rather than entering) the metal, since causes (*e.g.* sudden lowering of temperature) which would check the outflow of gas will diminish the intensity of the charge and *vice versa*.—W. H. P.

Enzymes of oxidation ; Contribution to the theory of ——. Peroxidase- and catalase-reactions of formaldehyde and acetaldehyde. G. Woker. Ber., 1914, 47, 1024—1029.

The peroxidase-, catalase-, and reductase-actions of vegetable and animal juices are regarded as reactions of the same substance, which is aldehydic in nature and identical with the oxygenase of Chodat and Bach. In presence of hydrogen peroxide it first forms a secondary peroxide, R.CH(OH).O.OH, capable of reacting with more hydrogen peroxide and liberating oxygen (catalase-action), or of transferring oxygen to chromogens (peroxidase-action). Both these actions may occur at the same time, or, owing to the presence of promotive or inhibitive agents, one or other may be greatly accelerated or completely suppressed. In absence of hydrogen peroxide and atmospheric oxygen, the aldehydic substance may exert a reducing action, *e.g.*, convert colours into their leuco-compounds (reductase-action). Amongst the evidence mentioned in support of this theory are the facts that the catalase- and peroxidase-activities of plant juices are destroyed at the same temperature (78°—80° C.) and cannot be separated by dialysis. Moreover formaldehyde shows quite typical peroxidase- and catalase-actions. Both acetaldehyde and purified benzaldehyde behave as peroxidases (produce a blue colour from benzidine in presence of hydrogen peroxide). Benzaldehyde, however, shows no catalase-action and, indeed, greatly increases the stability of hydrogen peroxide.—J. H. L.

The metric carat. Times, April 1, 1914. [T.R.]

On April 1st, 1914, by an Order in Council of Oct. 14, 1913, the metric carat of 200 milligrammes was ordained the legal standard of weight for precious stones and pearls. By the beginning of 1912 the use of the metric carat had been legalised in fifteen countries, including France and Germany, whilst last year it became the legal standard in the United States (see this J., 1913, 1132).

MR. H. T. PINNOCK IN THE CHAIR.

A CHEAP FORM OF ROTATING CATHODE AND ANODE FOR RAPID ELECTROLYTIC ANALYSIS.

BY ERNEST A. LEWIS.

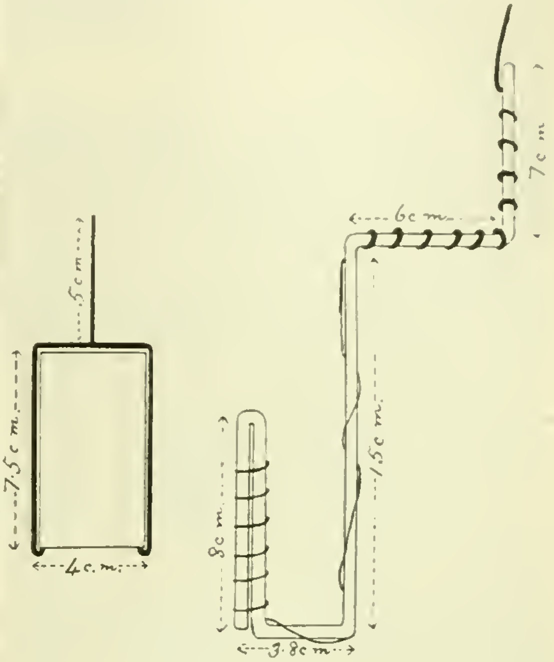
When the rapid method of electrolytic analysis was introduced the apparatus usually contained from 20 to 40 grms. of platinum. I believe that a rotating anode containing about 5 grms. of platinum and made largely of glass is about the smallest weight of platinum recommended. The continuous advance in the price of platinum makes it necessary for technical work to use cheaper metals if possible, and to reduce the weight of platinum in the anode to a minimum. The use of silver and amalgamated brass wire gauze cathodes has been recommended, especially for the assay of zinc. The rotating cathode which I use for zinc determinations is made of copper gauze, 20 meshes to the inch, supported by stiff copper wire which projects from the side and helps to cause vigorous circulation of the liquid. The anode is made of ⅛ in. glass rod, bent to the shape shown in the diagram. 14 inches of platinum wire of the size 1 grain equals 1 inch, are wound round the glass as shown. The platinum wire is connected to some electrical D.C.C. bell wire and the joint is made perfect by a small piece of platinum foil being wrapped round the joint, which is then wrapped round with adhesive electrical tape. The total weight of platinum is about 1 grm. The shape of the anode causes the liquid to thoroughly mix. The apparatus has been used successfully for determining zinc in alloys after the removal of copper, tin and lead. The current used being 2 amperes in a caustic soda solution.

If an ammoniacal solution or acetic acid solution is used the cathode must be of silver or the whole of it must be silver plated.

The apparatus has also been used for determining copper rapidly from a solution containing about 6 c.c. of strong nitric acid and 10 c.c. of strong sulphuric acid in about 150 c.c. of solution; using 3 amperes and heating to about 70° C. before putting in the copper cathode 0·5 grm. of copper is deposited in about 1 hour. It may seem rather unscientific to use copper cathodes to determine copper, but in practice it is quite satisfactory; if the solution is diluted to about 300 c.c. by washing in, about ¼ hour before the end, with cold water, the cathode can be rapidly lifted out and washed without any risk of re-solution; of course the liquid can be syphoned off if preferred, but this complicates the operation. After the cathode is weighed it can be used again for 4 or 5 determinations, when the deposited copper can be carefully dissolved off in dilute nitric acid. It is, of course, not possible to ignite a copper cathode, but it is not necessary. The copper cathodes are easy to make, they cost less than 6d. in material, and the anode only costs about 8s. The anode will safely carry a current of 3 amperes.

I endeavoured to plate a cathode with platinum, but the experiment was not successful, owing to the ease with which platinum is deposited on copper or silver by simple immersion. It is my intention to make a silver cathode and hope to be able to plate it with a thin coating of gold, and then to deposit a thin layer of platinum on the gold. If this is successful the silver cathode will be to all intents and purposes equal to a platinum cathode, and at a fraction of the cost.

It is also possible to use the current direct from the Corporation mains, without the use of accumulators. An 8 lamp accumulator charging board is used, and by the use of 8, 16, and 32 C.P. carbon lamps, giving ⅛, ¼ and ½ ampere respectively, a current varying from ⅛ ampere to 4 amperes can be obtained. The whole apparatus, including motor, cost about £5.



DISCUSSION.

Mr. J. E. STACEY JONES said he had used almost identical cathodes, with the exception that the gauze was replaced by plain foil. He had used brass sheet cathodes, about 32 or 34 standard gauge, and although he had used them chiefly for electrolysis in cyanide solutions, with gold, silver, and other metals, he saw no reason why they should not be used in ordinary laboratory work. Such cathodes were effective and had the advantage that they could be made easily and quickly. The brass foil required little cleaning and retained its brightness. Gold cathodes were effective but not gold anodes, because they would be ineffective if it were necessary to remove the deposit with *aqua regia*. In cathodes gold sheet of 15 c., of about platinum thickness, was cheap and serviceable. Copper could be removed by nitric acid. The objection with gold, however, was that one could not adopt ignition because 15 c. melted at a low temperature. Still a superior 14-carat gold cathode could be obtained for about £1, as compared with £10 for a platinum cathode. The method of obtaining electricity from the Corporation mains by carbon lamps might be convenient, but it was highly expensive.

London Section.

Meeting held at Burlington House, on March 2nd, 1914.

MR. E. GRANT HOOPER IN THE CHAIR.

AN APPLICATION OF CALCIUM CARBIDE IN THE FORMATION OF ALLOYS.

BY W. R. HODGKINSON, PH.D.

THE powerful "reducing" action exerted by acetylene on some salts has suggested that calcium carbide would under suitable conditions be useful in some metallurgical processes. In some early experiments a mixture of carbide and borax or carbide and sodium chloride was found to be a most efficient de-oxidising flux for copper and some copper alloys—as bronzes—cupro-nickel, &c., perfectly bubble-free castings being obtained. About one ounce of carbide to the usual amount of borax, was quite sufficient for each 10lb. pot of metal when added before the last stirring. With brasses, bronzes, or cupro-nickel, a good time to add the carbide-borax was found to be at the first melt when the last portions of copper, &c., were being added.

A considerable number of metallic oxides are reduced to the metallic state by carbide, but unless the metal is very fusible or a large amount of flux—borax—sodium or magnesium or barium chlorides—be employed, the infusible calcium oxide and any separated carbon or free carbide hold up the metal in shots or globules.

Attempts to reduce some of the rarer oxides, as those of cerium, zirconium, &c., and form alloys with copper failed at ordinary coke-furnace temperatures.

It appeared probable, however, that the halides of these rarer metals might be reduced by carbide which would at the same time form a calcium halide capable of acting as a flux. Trials with copper, lead, silver, zinc, and other metallic halides proved that, at suitable temperatures, reduction was complete and the calcium halide (chloride) formed a fairly efficient flux but the separation of the metal was retarded by the liberated carbon. The addition of salt, barium chloride, or borax (none of which has any action on carbide) overcame this difficulty.

The liberated carbon sometimes takes the graphitic form. Experiments with cerium chloride ($CeCl_3$), carbide, and metallic copper showed that cerium was reduced and taken up by the copper, alloys containing 6 per cent. and more of cerium being obtained.

It may here be noted that a convenient method of obtaining metallic chlorides in a state ready for further metallurgical work is to drop a mixture of metallic oxide and ammonium chloride into a red hot crucible, in small portions at a time. A very slight excess only of the ammonium chloride is necessary. In most cases the chloride is obtained in the melted state.

Two methods have been employed for obtaining alloys; one in which the main constituent—say copper—was melted and a mixture of the halide of the alloying metal and carbide then added; and, a better plan, where both, or all, metals for the alloy were in the form of halides roughly mixed with the calculated amount of carbide and in the case of low melting point metals some additional flux—as borax or salt. For alloys of high melting point, such as nickel and manganese, the carbide alone acted perfectly.

The chlorides and fluorides of most of the common metals react energetically with carbide provided the starting temperature is high enough—somewhat like the aluminium thermite reaction. As far as has been ascertained, the best starting temperature is one a little higher than the melting point of calcium chloride or other halide employed. The results have certainly been better where the carbide—metallic halide mixture has been introduced in successive moderate quantities into an already hot crucible than by slowly heating up a cold charge.

Employing this method—the hot crucible—no difficulty has been found in making copper—manganese or copper-nickel of almost any desired content of Mn or Ni, using manganese chloride or nickel chloride and either copper turnings or copper chloride. Similarly with nickel-manganese, or cobalt-manganese both metals as chlorides.

Tantalum, titanium, zirconium, and other metals which form salts of the types, K_2TaF_5 or K_2TiF_6, have been reduced and alloyed with copper. From one product containing above 20 per cent. Ta most of the tantalum segregated out during cooling and was left as a metallic powder on solution of the alloy is dilute acid.

From manganese chloride alloys have been obtained with tin, bismuth, antimony, and lead, employing these metals in the metallic state. The first product with lead, using the metal, contained 5·6 per cent. Mn: using $PbCl_2$ higher proportions of manganese were obtained. (These products from the microstructure seem to be suspensions of metallic manganese in lead.)

The tin and bismuth "mixtures" or solutions of manganese are only so far interesting that with more than 10 per cent. Mn they show decided magnetic properties.*

In cases where iron and aluminium free alloys are required the carbide reduction may be of value. Only in the cases of nickel, cobalt and iron with manganese did there appear to be any carbon taken up. A manganese cobalt alloy for instance, contained, Mn 38, Co. 59 and graphite 3 per cent.

The method and some of the products are being further investigated.

Specimens of alloys, such as Cu-Mn, Cu-Ce, Cu-Ta, Cu-Ti, Bi-Mn, Sn-Mn, Sb-Mn, Co-Mn, Ni-Mn, prepared by the process, and having in most cases atomic proportions of each element, and micro-photographs, were shown at the meeting.

I am indebted to Capts. Hunter and Macrae for analysis and other help..

DISCUSSION.

Mr. E. **GRANT HOOPER** said Professor Hodgkinson had struck out a new line in this utilization of calcium carbide in the preparation of alloys. He thought the paper introduced an interesting and he trusted an important departure in connection with the preparation of alloys.

Professor **HODGKINSON** said he was reserving an account of the properties of some of the alloys. He only spoke of the method because he thought it would be useful, and he was sure there was room for its development. There was a difficulty. Some of the halides were volatile, necessitating a careful adjustment of temperatures, but he thought it was possible in most cases to arrange matters and obtain the product with little loss.

Meeting held at Burlington House, on Monday April 6th, 1914.

PROF. W. R. HODGKINSON IN THE CHAIR.

THE VISCOSITY OF RUBBER SOLUTIONS.

BY R. GAUNT, M.SC., PH.D.
(Scientific and Technical Department, Imperial Institute).

Considerable interest attaches to the viscosity of rubber solutions, not only because they are colloidal solutions, but also on account of the suggestion put forward first by Axelrod[1] and afterwards by Schidrowitz and Goldsbrough[2] that the viscosity of a rubber solution stands in intimate relationship with the quality and technical value of the rubber.

Schidrowitz[3] regards the so-called "nerve" of rubber as due to three factors:—(a) Mechanical structure as indicated by the film structure of fine hard Para, and brought about by the method of coagulation; (b) physical structure or colloidal aggregation of the rubber particles; (c) chemical structure or molecular complexity.

The mechanical structure of crude rubber is largely broken down in the washing and mixing operations, and is therefore only a small factor in the quality of manufactured rubber. Schidrowitz suggests that viscosity measurements connote the physical and chemical structure of rubber although the exact relation is uncertain. He states[4] that within the same species viscosity measurements are a means of determining strength and vulcanising capacity; comparing species with species, however, this does not hold directly.

Beadle and Stevens[5] however, found that although some relationships can be detected, the general results of viscosity determinations are not in accordance with those obtained by vulcanisation.

---

* Their properties will be described in a further communication.

[4] "Rubber," p. 165.

[5] "The Rubber Industry," pp. 260 and 270.

Recently the viscosity of rubber solutions has been submitted to systematic study by G. S. Fol[6] who points out several precautions that must be taken in making viscosity determinations :—

(1) Comparative results can only be obtained by using a viscometer of standard dimensions, the differences in the results obtained with two different viscometers being much greater in the case of concentrated solutions than in the case of dilute solutions.

(2) The determinations must be made at a fixed temperature. The absolute viscosity of a rubber solution diminishes with rise of temperature. The relative viscosity however remains practically constant between 20° and 70° C.

(3) The rubber should be dissolved as completely as possible.[7] When the rubber is only partially dissolved the solution has for the same concentration a slightly less viscosity than when the rubber has been dissolved as completely as possible. This, Fol thinks, is probably due to the fact that the resins dissolve most readily and have very probably a lower viscosity than rubber itself.

(4) Viscosity is influenced by strongly shaking when preparing the solution, presumably, according to Fol, in consequence of the insoluble constituents being suspended in such a finely divided condition in the solution that they cannot be segregated by filtration through glass wool. He concludes that these particles contribute to viscosity in a larger measure than if one introduced into the solution the same weight of rubber.

Recently[8] H. P. Stevens by fractionally dissolving rubber in benzene, obtained fractions of different viscosity but he attributes the variations to differences in the resin content of the various fractions.

In the following experiments on the viscosity of rubber solutions the method of procedure was almost identical with that suggested by Fol. The majority of the experiments were made with the following different kinds of rubber :—

(*a*) A pale thin plantation crêpe Hevea, coagulated by means of acetic acid.

(*b*) Fine hard Para,

(*c*) Castilloa, prepared by centrifugalisation,

(*d*) Funtumia sheet,

(*e*) Ceara biscuits.

These rubbers had the following composition in the dry state :—

	Plantation Hevea.	Fine hard Para.	Castilloa.	Funtumia.	Ceara.
	per cent.	per cent	per cent.	per cent.	per cent.
Caoutchouc	93·8	94·6	85·8	86·2	91·2
Resin	3·1	3·3	13·8	11·9	4·8
Protein	2·7	1·8	0·3	1·7	3·0
Ash	0·4	0·3	0·1	0·2	1·0

The dry rubber was comminuted as finely as possible by means of scissors. A weighed quantity was placed in a stoppered bottle with a definite volume of solvent, shaken for two or more hours, and then allowed to stand over night. Next morning the solution was filtered through cotton wool and the concentration was determined by evaporating 10 c.cm. of the filtered solution *in vacuo* in a tared weighing bottle.

The viscosity was determined by means of an Ostwald viscometer in a thermostat which was maintained at a temperature of 20° C. ± 0·1° C.

The solvents employed were :—

Benzene, purified by repeated shaking with concentrated sulphuric acid, washing with water and alkali, finally drying and redistilling. In some cases the benzene was further purified by freezing.

Ether, purified by shaking with water, then drying by means of calcium chloride, and finally distilling over sodium.

Petrol, redistilled, the fraction distilling below 50° C. was employed.

Toluene, purified by repeated shaking with concentrated sulphuric acid, washing with alkali and water, drying by means of calcium chloride, and redistilling. The fraction distilling between 110° and 111° C. was employed.

Commercial xylene.

Chloroform purified by washing with water, drying and redistilling.

The Solubility of Rubber.

Rubber shows considerable variation in the extent to which it will go into "solution." Thus whereas the Castilloa and Funtumia rubbers examined mix with solvents in all proportions, the Para and Ceara rubbers are only partially "soluble." This fact is of considerable moment when one is drawing conclusions from the viscosity of rubber solutions as to the properties of the original rubber.

The following table shows the extent to which the Para and Ceara rubbers went into solution when the comminuted rubber was shaken with solvents for 2—3 hours and the concentration of the solution determined next day.

Solvent.	Weight of rubber per 100 c.cm. solvent.	Concentration of solution produced (grams per 100 c.cm.).			
		Fine hard Para.	Fine hard Para crêped 45 min. in the cold.	Plantation Para.	Ceara.
Benzene	0·5 grm.	0·24	0·26	—	0·30
	1·0 grm.	0·48	0·56	0·92	0·74
Ether	1·0 grm.	0·41	0·54	0·54	0·72
	2·0 grms.	0·84	1·03	—	1·43
Petrol	1·0 grm.	0·27	0·46	0·32	0·67
	2·0 grms.	0·72	0·99	—	1·59

A noticeable feature of the above results is that the greater quantities of rubber yield a rather more than proportionate amount of dissolved matter to the same quantity of solvent. It would appear therefore that the dissolved rubber causes a partial solution of the insoluble constituent.[9]

Fine hard Para is the most insoluble of rubbers, especially in the unwashed condition. In an experiment in which two grams of resin-extracted fine hard Para were extracted in a Soxhlet with benzene only 1·03 grams went into solution.

As will be seen, however, from the above results passing fine hard Para through the washer for 45 minutes in a stream of cold water raises the solubility considerably. Heating with solvents also increases the amount going into solution, as the following results show :—

	Concentration of solution produced. per cent.
0·5 gram Fine hard Para was shaken with 50 c.cm. xylene	0·49
0·5 gram Fine hard Para was heated to 100° C. for several hours with 50 c.cm. xylene	0·65
0·5 gram Fine hard Para which had been crêped for 45 minutes in a stream of cold water was heated to 100° C. for several hours with 50 c.c. xylene ..	0·75

To explain the partial solubility of rubber in solvents Caspari has recently[10] revived the view of Gladstone and Hibbert[11] and Seeligmann[12] that rubber contains a soluble and an insoluble caoutchouc. According to Weber[13], however, the amount of insoluble matter in rubber can be reduced by successive extractions with chloroform, to a very small percentage, and according to

Spence[14] it consists largely of protein. Even Caspari admits that his "pectous form" of caoutchouc "may conceivably be simply a residue of sol-forming rubber which has failed to burst its way out of a micellular framework possibly consisting of the rubber constituent commonly referred to as protein," but he maintains that there is no proof that the nitrogenous matter encloses rubber particles. And indeed it seems remarkable at first sight that the small amount of protein, if it is actually protein, should prevent twenty to thirty times its weight of caoutchouc from going into solution. However, there is yet no convincing proof that an insoluble pectous form of caoutchouc exists. Indeed the *Castilloa* and *Funtumia* rubbers examined mix completely with solvents and *a priori* one would hardly expect the pectous form of caoutchouc to exist in some species of rubber and not in others. Moreover there is no sharp line of demarcation between the soluble and insoluble forms of caoutchouc, for as is apparent from the above results, crêpeing the rubber as well as heating with xylene causes more caoutchouc to pass into solution; from which one may conclude that the partial solubility of Para and *Ceara* rubbers is due, at any rate to some extent, to the structure of the rubber or state of aggregation of the caoutchouc.

The fact however that part of some rubbers remains undissolved in the usual method of making solutions for viscosity experiments considerably detracts from the value of viscosity determinations unless one can assume that the undissolved portion has the same viscosity as the dissolved caoutchouc. An attempt to ascertain if this was the case by treating the insoluble residue with fresh solvent failed owing to the very slow rate of solution of the residual rubber. H. P. Stevens.[15] however, has determined the viscosity of different fractions of rubber in benzene and finds only small differences which he explains was due to the varying amounts of resin present.

Viscosity of Rubber in Different Solvents.

Rubber produces with different solvents "solutions" of different viscosity. In the following experiments the viscosity of solutions of various rubbers in benzene, chloroform, petrol and ether was determined at different concentrations.

The relation between the viscosity in the different solvents is shown in the adjoined curves (Figs. I.—III.).[16] It will be seen that ether produces solutions of least viscosity. Benzene and chloroform, on the other hand, produce solutions of greatest viscosity. The plantation Para rubber examined gave a solution in benzene of low viscosity; this difference is shown in a greater degree in ethereal solution.

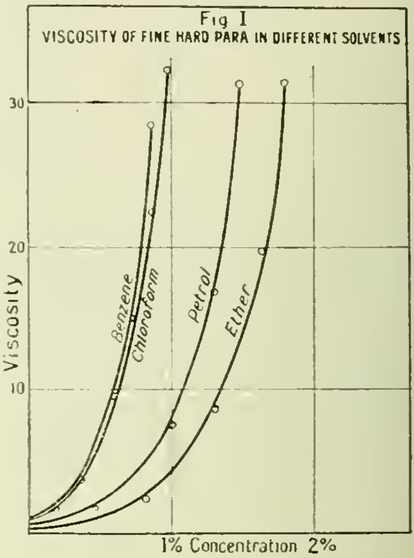

Fig I

VISCOSITY OF FINE HARD PARA IN DIFFERENT SOLVENTS

Viscosity of different Rubbers in Benzene Solution.

In order to compare the viscosity of caoutchouc in different rubbers it is necessary to make a correction for the amount of resin (which may be considerable in the case of *Castilloa* and *Funtumia* rubbers). When this is done and the viscosity is plotted against the concentration, the curves shown in Figure IV. are obtained. The fine hard Para and *Castilloa* curves practically coincide, from which one might conclude that the caoutchouc in the *Castilloa* sample and the soluble caoutchouc in the fine hard Para are of equal quality. When the fine hard Para, however, had been passed through the washing machine for 45 minutes in a stream of cold water it produced solutions of much less viscosity. The *Castilloa* rubber, after washing under the same conditions

[14] Journ. Inst. Comm. Res. Tropics, 1907, No. 13.

[15] *Loc. cit.*

[16] The curves for Funtumia rubber are similar to those fo Castilloa, and are omitted.

produced solutions of lower viscosity, but the change was not so marked as in the case of fine hard Para.

In order to compare numerically the viscosities of different rubber solutions two methods have been suggested. Schidrowitz suggested drawing a tangent to the curve at 1 per cent. concentration and taking the tangent of the angle which this line makes with the abscissa as a measure of the viscosity. Fol on the other hand suggests taking the area enclosed by the curve, ordinate, abscissa, and a line drawn from the curve at 1 per cent. concentration perpendicular to the abscissa. Both these methods are arbitrary, and moreover it will be seen from the curves (Fig. IV.) that in the case of the fine hard Para and *Castilloa* rubbers the viscosity of the solution will become practically infinite before 1 per cent. concentration is reached.

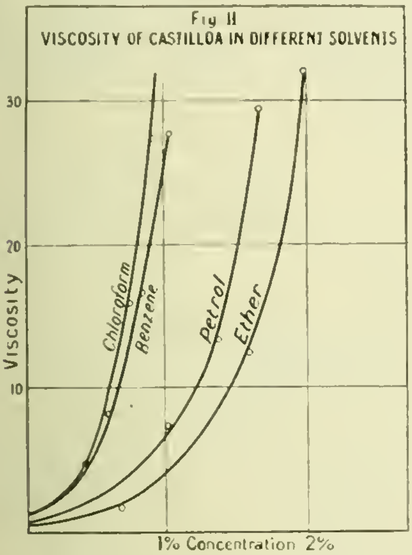

Fig II
VISCOSITY OF CASTILLOA IN DIFFERENT SOLVENTS

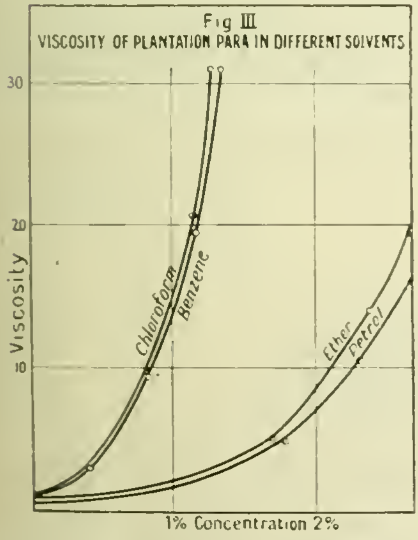

Fig III
VISCOSITY OF PLANTATION PARA IN DIFFERENT SOLVENTS

A simpler method of comparing the results would be to find the relation between viscosity and concentration and express this as a straight line.

Various formulæ[17] have been proposed for connecting the viscosity of solutions with the concentration, but they have had only a limited application.[18]

The viscosity of rubber solutions, however, appears to obey a logarithmic equation, such as[19]

$$\eta = k^{x}$$

(where η_x = viscosity at concentration x, x = concentration, and K = constant), for when the log. viscosity is plotted against the concentration in benzene solution in the case of the rubbers examined the straight lines shown in Fig. V. are obtained.

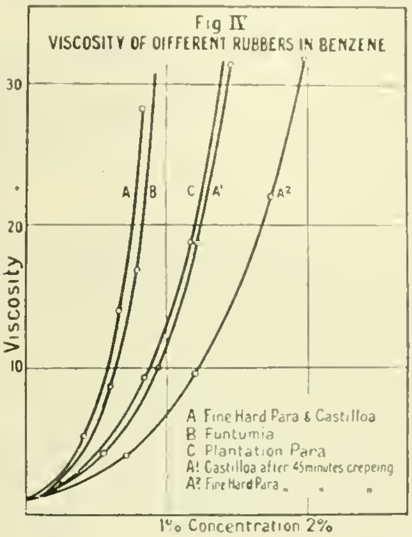

Fig IV
VISCOSITY OF DIFFERENT RUBBERS IN BENZENE

The inclination of these lines with the abscissa would seem to be the simplest way of numerically comparing the viscosity of rubber solutions.

The actual figures given by the three methods are the following :—

	Schidrowitz.	Fol.	Proposed method.
Fine hard Para	∞	∞	68
Castilloa	∞	∞	66
Funtumia	6000	390	65
Plantation Para	1300	180	55
Fine hard Para after 45 min. washing	1000	120	43

It will be noticed that the proposed method does not show such great differences between the rubbers examined as the other two methods. If viscosity connotes the quality of rubber one would expect small differences, as the rubbers were all of very good quality. Judging from the viscosity of fine hard Para after washing, the plantation Para probably owes its position to the fact that it had been crêped.

Change in Viscosity of Rubber Solutions.

It is well known that rubber solutions are liable to change in viscosity. The first mention of the fact was made by Woudstra,[20] who observed that toluene solutions diminished in viscosity on standing. Fol[21] attributes this change to the gradual deposition of insoluble matter in suspension which passes through the filter. Gorter[22] observed that solutions of rubber in benzene exposed to sunlight diminished rapidly in viscosity, and showed that this was accompanied by oxidation. He found also that benzene solutions of rubber diminish slowly in viscosity even in the dark and when access of air is prevented.

[22] Mededeelingen over Rubber Nos. 1 (1911) and 2 (1912) (Departement van Landbouw, Nijverheid en Handel, Java).

In a preliminary experiment the writer observed a solution of rubber in commercial benzene left exposed in the laboratory to diminish 30 per cent. in viscosity at ordinary summer temperatures.

Heat as well as light appears to increase the diminution in viscosity of rubber solutions.

A solution of plantation rubber in commercial toluene was divided into two portions, each of which was maintained at 40° C. in a thermostat, one portion being protected from the light. It was found that the viscosity diminished as follows :—

	Times of efflux in seconds.	
	Protected solution.	Exposed solution.
Initial	260	260
After 6 days	150	119
After 12 days	129	88

At higher temperatures the diminution in viscosity is more rapid. Schidrowitz and Goldsbrough[23] found that the viscosity of benzene solutions of rubber in some cases sinks to half its original value on heating for two hours on the water-bath.

At high temperatures the effect of light, or at any rate of ordinary daylight, on the viscosity of rubber solutions appears to be less marked than that of heat.

A solution of plantation rubber in commercial toluene was divided into two portions, each of which was heated in a conical flask under a reflux condenser on the water-bath, one of the flasks being protected from the light by means of a tin cone. The viscosity of each portion was determined at the commencement and at stated intervals with the following results :—

	Times of efflux in seconds.	
	Exposed solution.	Protected solution.
Initial	80·5	81·0
After 30 minutes	63·0	63·0
After 2 hours	53·0	55·0
After 4 hours	46·0	51·0
After 14 hours	39·0	45·0

The effect of light only begins to make itself felt after two hours ; at the commencement the solutions diminished in viscosity with the same velocity.

In the following experiments a solution of plantation rubber in commercial toluene[24] contained in a conical flask and protected from the light by means of a metal cone was heated under a reflux condenser on the water-bath. At the commencement of the experiment and at stated intervals the viscosity was determined at 20° C. The following results were obtained :—

	Times of efflux in seconds.					
	I.	II.	III.	IV.	V.	VI.
Initial	84	86	77	78	82	82
After 1 hour	62·5	61	60	58	61	60·5
After 3 hours	49·5	50	51	50	52	49
After 5 hours	44·5	46	47	46	47	42·5
Concentration (grams per 100 ccm.)	0·48	0·49	0·44	0·44	0·45	0·45

At higher temperatures the fall in viscosity is still more marked. A solution of rubber in toluene was heated in a sealed tube at 125—130° C. for six hours. The time of efflux fell from 220 seconds before heating to 29 seconds after heating.

In Gorter's experiments on the diminution of viscosity under the influence of light the rubber underwent oxidation. Bernstein[25] states however that xylene solutions of rubber diminished in viscosity under the influence of an ultraviolet light even in the absence of oxygen.

It was also found that heat alone in the absence of air caused diminution in viscosity of rubber solutions, as the following experiment shows :—

Test tubes were completely filled with xylene solutions of rubber, and closed with corks through which passed small glass tubes to allow for the expansion of the solution. They were then placed in boiling water and as soon as the expansion had ceased the openings of the glass tubes were closed by rubber caps. The solution thus out of contact with air was heated for two hours and the viscosity determined.[26]

	Times of efflux in seconds.		
	Fine hard Para.	Plantation Para.	Ceara.
Before heating	87	125	318
After heating	27	44	96

Rubber solutions therefore on heating diminish considerably in viscosity, apart from any oxidation which the caoutchouc may undergo.

Considering the magnitude of the change it is also difficult to believe that it is due to the separation of adventitious insoluble particles which have passed through the filter.

The phenomenon seems most easily explained by assuming that rubber in solution tends to undergo a physical change, the so-called "depolymerisation," slowly at ordinary temperatures, but much more rapidly as the temperature rises.

The rate of diminution of viscosity also varies with the time of heating, being greatest at the commencement. This is shown in the following experiments where the viscosity was measured at regular half hour intervals.

A was a solution of plantation Para rubber in toluene, heated under reflux on the water bath and protected from the light

B was a solution of *Castilloa* rubber in xylene heated in boiling water and also protected from the light.

	Times of efflux in seconds.	
	A.	B.
Initial	80·0	160
After heating 30 minutes	50·5	135
After heating 60 minutes	41·5	124
After heating 90 minutes	38·0	117
After heating 120 minutes	35·0	110
After heating 150 minutes	33·0	107
After heating 180 minutes	32·0	104

These results are shown graphically in Fig. VI.

The change in viscosity appears to follow the law :

$$x = a + b \log t$$

(where x = diminution in viscosity in time t.
a = diminution in the first time unit, 30 minutes,
b = increment of diminution with time).

For when the viscosity is plotted against the logarithmic value of the time straight lines are obtained (Fig. VII.). It is interesting that this relation is the same as that given by Schwartz[27] between extensibility and time in hysteresis measurements, namely the increment of extension plotted against the logarithm of the number of the cycle is a straight line.

---

[23] The Rubber Industry, p. 260.

[24] Toluene was used for studying change in viscosity at high temperatures in preference to benzene, because the ebullition of the latter is a disturbing factor.

[25] These results are not comparable amongst themselves as the concentrations (undetermined) are obviously very different.

[26] Zeitsch. Chem. und Ind. Koll. 1913, **12**, 193.

[27] The Electrician, 1910, **54**, 585 and 629.

A' Fine hard Para after 45 minutes crêpeing in cold water.
B' Castilloa after 45 minutes crêpeing in cold water.

FIG. VI

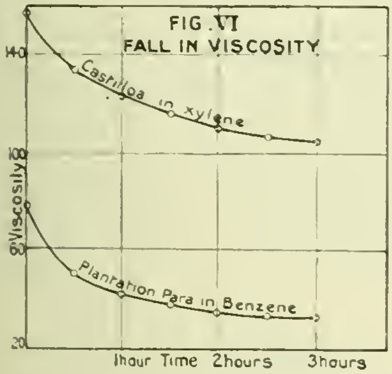

FIG. VII.

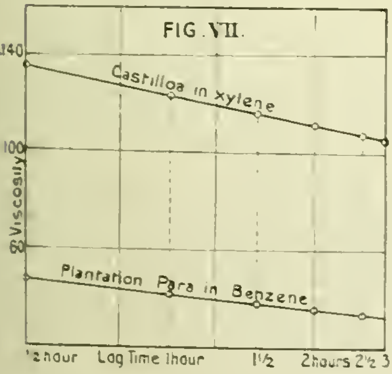

This is not surprising seeing that both phenomena are the result of internal work performed on the rubber, but the point of interest is that Schwartz found that when he examined various samples of rubber, and plotted the maximum extension per cycle against the logarithm of number of cycle, the rubbers arranged themselves in the order of their quality, the maximum extension with succeeding cycles being greatest in the case of fine hard Para. It would appear that the phenomenon is due to a property of rubber which persists not only in solution but also throughout vulcanisation.

Effect of Concentration on the Change in Viscosity.

The following experiments show the relationship of change in viscosity to the concentration.

Solutions of plantation Para in commercial xylene at different concentrations were heated in small flasks (closed with corks) in a water bath maintained at a temperature of 80° C. The viscosity was determined at the commencement and at stated intervals with the following results :—

	Times of efflux.					
Initial	61·5	73·0	87·0	104·5	138·0	187·0
After 30 min...	53·0	62·0	74·0	89·5	120·0	161·0
After 1 hour..	51·0	60·0	70·0	81·5	111·5	148·0
After 2 hours	46·5	57·0	64·0	73·5	105·0	132·0
After 3 hours	44·0	56·0	62·0	69·0	98·0	124·5
Concentration (grams per 100 ccm.)	0·4	0·48	0·54	0·60	0·73	0·82

The relation between these results is best seen in Fig. VIII., where the times of outflow are plotted against the logarithmic value of time of heating.

FIG. VIII

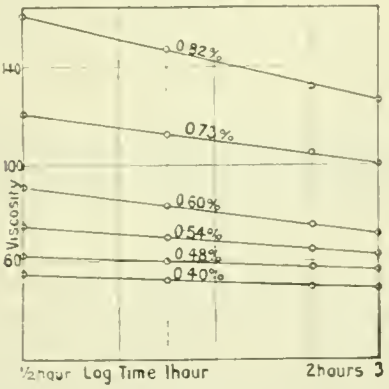

Fig. VIII. Showing rate of diminution of viscosity at different concentrations (Plantation Para in xylene at 80° C.)

Change in Viscosity of Rubber in different Solvents.

The following experimental results show the change in viscosity of plantation Para in different solvents, when heated to 80° C.

	Times of efflux.					
	Purified benzene solutions.		Purified toluene solutions.		Commercial xylene solutions.	
	I.	II.	I.	II.	I.	II.
Initial	87·5	75·0	87	84·5	91	87·0
After 1 hour..	74·5	67·0	—	—	69	70·0
After 2 hours..	72·5	66·5	77	76·5	61	64·0
After 3 hours..	72·0	66·0	73	72·5	57	60·0
Concentration (grams per 100 c.c.)	0·43	0·40	0·42	0·44	0·50	0·51

It is noteworthy that the change is more marked in the case of xylene solutions than in the case of the benzene and toluene solutions. In purified toluene solutions the diminution in viscosity appears less than in commercial toluene (cf. the results on p. 450) though this may be explained by the fact that toluene solutions on the water-bath will attain a higher temperature than 80° C. A similar difference is observed between solutions in pure benzene and solutions in "90 per cent. benzol" on the water bath, as is seen in the following results :—

	Times of efflux.	
	Pure benzene.	Commercial benzene.
Initial	80	77
After heating 1 hour	73	64
After heating 2 hours	71	62
Concentration (grams per 100 ccm.)	0·40	0.40

The effect of the addition of small quantities of the usual impurities in benzene (carbon bisulphide, thiophen xylene) was also studied. With the exception of xylene they did not cause any increased diminution in viscosity. A solution of rubber in pure benzene was divided into two portions. To one portion 0·5 per cent. commercial xylene was added, and both heated on the water bath.

	Times of efflux.	
	Pure benzene.	Pure benzene + 0·5% of xylene.
Initial	71·5	71·5
After 1 hour	65	61
After 2 hours	63	58

It would seem therefore that the presence of xylene or higher hydrocarbons in commercial benzene may affect the viscosity of rubber solutions. Hence the importance first indicated by Schidrowitz, of working with pure solvents.

Change in viscosity of different rubbers in solution.

The simplest way of comparing the diminution in viscosity of different rubbers is to take solutions of equal or approximately equal viscosity and to determine the extent to which the viscosity is destroyed by heat.

This has been done for the rubbers examined. Care was taken that the solutions were made under as near as possible the same conditions. The comminuted rubber was shaken 2½—3 hours in a rotatory shaker with the quantity of xylene necessary for the production of a solution of definite viscosity. The same sample of xylene was used throughout.

After determining the viscosity the solutions were heated in boiling water for two hours and the viscosity redetermined. The following results were obtained :—

	Time of efflux in seconds.		Percentage diminution.
	Before.	After.	
Fine hard Para	103 111 105	46 46·5 48	57
Plantation Para	108 109 115	68 65 72	37
Fine hard Para which had been crêped 45 minutes in the cold	118	81	30
Funtumia	104 101 100	78 70 81	26—30
Castilloa	111 107	80·5 78·0	28
Ceara	118	90	23

The order in these results is quite different from that obtained when comparing the viscosity of rubber solutions at different concentrations, all the Hevea rubbers showing higher percentage diminution in viscosity than the other species.

The explanation of the change in viscosity of rubber solutions depends on the one hand on the nature of viscosity and on the other hand on the structure of the rubber gel. Assuming as is generally supposed that viscosity is due to friction of the ultimate particles[28], and assuming also that rubber consists of aggregated caoutchouc micelles[29], it is only necessary to suppose that the caoutchouc goes into "solution" in a more or less aggregated condition, with a tendency to de-aggregate or "depolymerise."[30] In this case the high viscosity of rubber solutions is due to the presence of large aggregates, which are disrupted by heat, and the percentage diminution in viscosity of different rubbers on heating will be a measure of the proportion of large aggregates in the solution. The larger the aggregates the more heterogenous the "solution," hence the difficulty of obtaining absolutely concordant results for the initial viscosities of solutions even of the same rubber and of the same concentration unless one works under absolutely uniform conditions.

The phenomenon of "de-aggregation" is not limited to the solution.[31] Bernstein has shown that when rubber is heated in the absence of air, the viscosity of the solution is less than that of the solution of the initial rubber. Crêpeing brings about "de-aggregation" in the same way.

The so-called hysteresis of vulcanised rubber is probably due to "de-aggregation," for it follows the same law, which would give some theoretical justification for supposing that the diminution in viscosity which a rubber solution undergoes on heating indicates at any rate one important factor in the quality of rubber, for one might conclude from Schwartz' results that although during washing and mixing the rubber may become "de-aggregated," the better rubbers do not do so to the same extent as the inferior rubbers or that, during vulcanisation, the better rubbers return to a higher state of aggregation.

Meeting held at the Municipal School of Technology, on Friday, April 24th, 1914.

MR. JULIUS HÜBNER IN THE CHAIR.

A CONTRIBUTION TO THE HISTORY OF DYEING, WITH SPECIAL REFERENCE TO SCOTLAND.*

BY JULIUS HÜBNER, M.SC.TECH., F.I.C.

When I concluded my first paper on the History of Dyeing†, I had some doubt as to whether research with regard to the history of industries would be appreciated. Soon after its publication, however, any such doubt was dispelled by the many kind and complimentary comments which I received, and nothing could have more strengthened my decision to proceed with this work than the letter addressed to me by Mr. Rhys Jenkins of the Patent Office, in which he not only expressed his appreciation but showed his sincere interest and sympathy in this work by placing at my disposal a large amount of information upon the history of dyeing in England which he had collected during many years. The new sources of information which had thus to be investigated in order to present the history of dyeing in England in a complete form, soon forced the conclusion upon me, that this part of the work, which I intend to prosecute, will of necessity extend beyond the scope of any paper.

---

[28] *Vide* Powell, Journ. Chem. Soc., 1914, **105**, 1.

[29] *Vide* Svedberg Ber. d. d. Chem. Gesell., 1914, **47**, 12.

[30] The use of the term "depolymerisation" for denoting this change is open to criticism, because one generally understands by the expression a quite different phenomenon. For this reason the writer suggests the use of the word "de-aggregation" instead.

* See this Journal, Nov. 29, 1913, pp. 1043 *seq*.

† A Glossary and the complete titles of publications from which extracts have been quoted will be found at the end of the paper. The latter are referred to in the text by corresponding numbers.

I, therefore, devoted in the first instance my attention to the history of dyeing in Scotland, which I hope to present in this paper in a fairly complete form.

A large influx of Flemings into England occurred as early as the 12th century, and, encouraged by Henry I., many went from England to Scotland.[12]

Chalmers informs us that from the beginning of the Scoto-Saxon Period "Scotland . . . enjoyed the benefit of a domestic manufacture. Many of the new settlers in the towns during this time were named from the nature of their trades. Thus Ernulf the *dyer*, Arnald the *dyer* and William the *dyer* were all burgesses of Perth during the reign of William the Lion,[*] and William the *dyer* lived in Kelso during the same reign.[†]

Chalmers[9] proceeds to state that "her people manufactured the wool of their flocks. Their woollen fabrics were regulated by the assize of David I. The charter of King William the Lion to Inverness speaks of cloth dyed and shorn, which should not be made without the borough, contrary to the assize of David.[‡] The *constitutio nova* of Glasgow also speaks of cloth dyed and shorn. Much wool was however exported. They manufactured their own flax and their own leather, and Dyers and Goldsmiths were in every town."

Fordun informs us that David I. "enriched the ports of his kingdom with foreign merchandise, and to the wealth of his own land added the riches and luxuries of foreign nations; that he changed its coarse stuffs for precious vestments and covered its ancinet nakedness with purple and fine linen."[12]

We also find in a charter[11] of Philip Earl of Flanders, who fell at the siege of Acre in 1191, that he granted he monks of Melrose a passage through his territories free of toll or exaction.[§] The brethren of Melrose, and also he monks of Scone, took over the raw Scotch wool from heir monastery lands to the woollen manufactories of Flanders, and their wool became widely known and much alued by the Flemish weavers.

Of the crafts and occupations prosecuted in the burghs f the 12th century, the old laws and form of procedure nention bakers, brewers (male and female), fleshers, millers, fishers, tanners, skinners, shoemakers, dyers of loth, maltmakers, wine-taverners, tailors, saddlers and vool-combers.[8] During this century considerable attention was paid to the promulgation of laws regulating he woollen manufacture of Scotland, and from these ocuments authentic information is obtained that dyeing was actually practised at this early period. Thus we find hat a custom of 1d. was imposed on each bundle of madder imported.[5]

"The Lavves and Constitvtions of Burghs, made be King David the first, at the new Castell, vpon the Vater of Tyne," contained the following regulations with regard to the buying of wool and cloth:—"Ane tranger Merchand sovld buy from Burgessis.[¶] Na tranger marchand nor aliene may buy wool, hydes, nor ther merchandise, or without borgh, bot fra ane urges;"[15] and no one but a burgess could buy wool to dye, or make or cut cloth [8] (**20).

In the Acts of Parliament of Scotland[6][††] we find under makyn of cloth and littyn of woll," that the dyeing of wool and the shearing of cloth was also confined to urgesses:—"Na man bot burges sall by woll to lytt a clathe to mak ne schere."

During the 12th century "the mercantile classes became ealthier and more important; the handicraftsmen eame more and more confined to the poor and the ufree. The merchant-guild made the practice of certain trades a ground of exclusion from the fraternity."[8] This was by no means confined to Scotland, because we find that Dutch, German and Belgian Guild Statutes ordain that no one with "dirty hands," or with "blue nails," should be a guild brother.

The latter prohibition no doubt refers particularly to woad dyers.

Among a few other trades in Scotland, dyers are specially referred to in chapter 94. I. 351,[6] in which it is set forth that they must not put their hands into the woad if they belong to the guild. "Of thaim that may nocht be in the gylde. It is to wyt that no thir lytstar . . . may be wythin the fredome of the gylde but gif he sal sorsuer to do that craft wyth his awne propir handis bot wyth servandis undir hym."

This law was rigorously enforced. We find in the "Articuli Inquirendi"[*] that it was "to be inquired be secret inquisition, and punished be the law . . . Give Litsters, or Sowters, quha are brether of the Gild vses their offices with their proper hands . . . and of Litster Burgesses quha puts their hands in the wadd."

A burgess was not allowed to work outside the burgh as long as there was work to be obtained within the burgh. This is especially set forth as regards woolcombers.[15][†] "Of Kemesters. Gif the Kemester passe forth of the burgh a landwart, thero to worke, and to vse their offices, hauand sufficient worke to occupie them within burgh; they sould be taken and imprisoned."

Special attention was also paid to the weavers who evidently had been accused of various offences which were considered against the interest of the burgesses:—"Wobsters[15][‡] sould be challenged, that they make over many lang thrummes, to the hurt of the people. 2). Quhen they take in claith with wechtes, and give. out againe the samine be wecht; they make the claith wak and donke, casting vpon it washe, vrine, and other thinges to cause it weight, and thereby halding a great quantitie of it to themselves. 3). They take evill and rotten zarne, and puttes it in the wob for hnist."

It is doubtful whether trades such as dyeing, weaving, shearing, etc., were at that time practised by the Scotch inhabitants in the burghs, because we find that the population was a very mixed one as far as nationality was concerned. When Edward I. made his progress north to receive the submission of the burghs, the names of the burghers were largely English and Flemish, and a grant of Earl David, brother of William the Lion, in conveying lands, addressed it "omnibus probis hominibus totius terrae suae, Francis, Anglis, Flamingis et Scottis."[12]

During the reign of William the Lion, Dundee had nine incorporated trades; among these are mentioned weavers and fullers, but not the dyers.[7]

In the Assize of Weights and Measures[5] mention is made of woad, madder and dyed wool in the following entry:—"Of walde." "And gyf ony schyp cum wytt walde he sal gyf for ilk frael at the entre twenty and twa penniis and at the furth passyng twenty five penniis and for ilk mesure that is callyt a settyng (a weight in Orkney, containing 24 marks) a half penny, and swa for ilk frael remaynand in the burgh of strange mannys vnsauld atoure the feste of Sanct Mertyn it sal gyf auchten penniis for the retret wardis," and further "of a foume of madyr or wauld or wauld on a hors 1d. Of a byrthing of madyr or walde to sel a halfpenny" and "of a staen of lyttyt wol a half penny."

Among the different burghs, Aberdeen played a most prominent part and valuable information as regards the early history of industries is to be found in its Records.[7] On the 12th February, 1222, Alexander II. granted a charter to Aberdeen:—"I likewise grant to the same, my burgesses of Aberdeen, that they have their Merchant Guild, the waulkers and weavers being excluded. . . . I likewise strictly forbid any one dwelling outwith my burgh Aberdeen within the Sheriffdom of Aberdeen to make or cause to make cloth, dyed or shorn, within the Sheriffdom of Aberdeen, save my burgesses of Aberdeen who are of the Merchant Guild. . . .

[‡] I. 670, Appendix III.

I strictly forbid anyone within the Sheriffdom of Aberdeen to make cloth, dyed or shorn, on pain of my full forfeiture. If however, any person's dyed or shorn cloth shall be found made in despite of this protection, I command my Sheriffs to seize the cloth, and to do therewith as was the custom in the time of King David my great-grandfather."

An exception to fullers and weavers is also made in a charter granted by Alexander II. to Perth and Stirling. Edward I. attempted the same exclusion in London, Winchester, Marlborough, Oxford and Beverley. From this one may trace the first instances of the long-standing conflict between the more plebeian crafts and the more wealthy merchant burgesses. In all countries, the weavers and their fellow craftsmen, the fullers and dyers, were the first to make their existence known as a combined body, and it is thus interesting to note that in Scotland as far back as the 12th century they were specially mentioned in a charter excluding them from the same privileges as the Merchant Guild.

The Burgh Laws, as regards the manufacture of cloth, seem to have been fairly uniform throughout Scotland because we find[9][*] that according to the *constitutio novo*, "no one could have a malt-kill without the burgh of Glasgow . . . no one without the burgh could make any cloth, either dyed or shorn."

No manufactured articles seem to have been exported from Scotland during the 13th century because we are informed[12] that "before the War of Independence the chief articles of export appear to have been hides, wool and salted fish. From a very early list of goods brought to Bruges from various countries Scottish exports at that time would appear to have consisted of "lainnes, cuir, fromaige et sui."[†]

Towards the conclusion of the Scoto-Saxon period, the Flemings had placed a commercial factory at Berwick-on-Tweed,[‡] and a commercial treaty with the court of Flanders during the year 1297 (Edward I.) stipulated that the Flemings should have free and secure trade in Scotland.[9][§]

The author has not been able to obtain much authentic information as regards dyeing and dyers during the 14th century.

In 1340[10] we find according to the Exchequer Rolls that a dyer "Stephen Tinctor" was Provost of Banff, whilst[||] a dyer "Ralph Tinctor" was one of the collectors of the new custom of the burgh of Linlithgow.

Chalmers[9] informs us with regard to Berwickshire, that "in this shire, like every other, there must have always been a domestic manufacture for private uses. In 1371 there existed a fulling mill at Lauder, which had perhaps come down from the Morvilles of the 12th century and was certainly forfeited by their representatives, Alan Le-Zuche and John Baliol.[¶]

Some information about the various guilds[7] during the 15th century may be gathered from records dealing with the custom of presenting miracle plays at certain church festivals. Bain informs us that these plays formed an important feature during the 15th century. Nearly every large city had its own company of performers, generally composed of the various trade corporations. In Aberdeen, as early as 1440, a leader was appointed, called Abbot of Bon-Accord, to conduct the play of Halyblude. Two years after his appointment an edict was issued, calling on the craftsmen to appear annually at "the offerand of Our Lady" at Candlemas:—"The Littistaris sal fynd, The Empriour and twa Doctouris and alsmony honeste Squiares as thai may. . . . The Wobstaris and Walkares sal fynd, Symion and his disciples. . . ."

In the Exchequer Rolls.[10][**] under Aberdeen, we find reference to a dyer (1416)—Alexander tinctor Burgess of Aberdeen, in connection with wool of the Sheriffdom of Banff and another one in 1448[10][*] with regard to an allowance for expenses "in the pursuance and dyeing (tincture) of woollen and linen garments for a play before the King."

When the crafts began to assume a position of importance in the burghs, the Legislation took more particular cognisance of them and for their better organisation and "conduction," the second Parliament of James I., held at Perth, passed an Act on 12th March, 1424, in which the weavers but not the dyers were included.[7]

In the Edinburgh Records, 18th May, 1451, "one Rede, a dyer, was admitted a burgess as in right of his father and he gave wine and spices."[8]

About the middle of the 15th century the exportation of wool and linen cloth was prohibited by Parliament. Thus under[15] "Crimes Qvhilk are nether capitall, nor pecvniall bot are punished be ane vther paine, as be escheit of moveable gudes, or vther wayes" among "Forbidden gvdes, the Paine of transporting of the samin, and ane catalogue thereof . . . wool[†] . . . and Linning claith,"[‡] and further restrictions were imposed upon merchants in regard to the selling of tapistry, silk and woad, etc., in the following act:—"Na persons dwelland outwith burrowes, vse ony merchandice, nor taip . . . silkis . . . wadd[15][§] . . .

A Statute of James II., passed 6th March, 1457, declared it to be "sene speedful that lit be cryit up and vsyt as it was wont to be, and that na litster be draper, nothir to by claytht, nor yet tholyt to sell, vnder the payne of eschet thairof."

In 1475[13] the "Websters" of Edinburgh petitioned the Common Council to "erect them into a Society." Their request was granted.

James III. granted two Charters of the 6th November, 1482, to Edinburgh which contained among other valuable privileges "to take Custom of several Sorts of Merchandise at their Port of Leith." Among the articles specified we find:—For one Tun of Wad . . . 13s. 4d., For a Pack of Wad . . . 1s. 0d., For a Pack of Cloth . . . 0s. 8d.

During the 15th century the trade between Scotland and the Netherlands was already of considerable import ance and in order to further encourage it "the Scot were allowed to send cloth of any measure to be dyed i Flanders and to be taken back to their country, but n cloth at all was to be sold there.[11] (1469.) The state o affairs cannot be more fittingly described than i Davidson's words in "The Scottish Staple at Veere."[1]

Scotland has in the Convention of the Royal Burghs for many centuries the governing authority in all matter of trade and commerce, "the oldest existing representativ body in Europe," and in the Staple, the organisatio of foreign trade, Scotland maintained in full force unt the end of the eighteenth, and endeavoured to reviv in the 19th century, an institution to which in oth countries parallels can be found only in the middle ages.

The first "Conservator of the Privileges of the Scot Nation in the Netherlands" was Andrew Halyburt and some valuable information has been obtained fro his Ledger.[2] This Innes describes as "our oldest exta Ledger or merchants' account book." This book h been in the General Register House at Edinburgh for long time. It is a thick folio, beautifully preserved in i original dark leather binding, and having the ba strengthened with bands and parchment thongs, ve much in the style of modern account books. Nea all the entries are written by Halyburton himself. Ea account is solemnly preceded by the names of "Jhesu and the money, where not otherwise expressed, is in common currency of the Netherlands and counted pounds, li; shillings, s; and groats, g. Halyburto residence was probably Middleburgh, a place of m importance to traders, during the period covered by Ledger, *i.e.* 1492 to 1503.

The following extracts have been selected as pa cularly suited to convey some idea of the prices, quality and quantity of merchandise sent by Halybur to Scotland as well as of those exported from Scotland to Holland. "Item in Apryll anno 94, bocht in Bery betwix Lorens and me a stek welwat blak lang 30½, pris of the ell 11s. 8g. Som, 17li. 15s. 10g." "li. 12. Anno 94 in Schir Thomas Todis schip. for a ton of Vaid lyk as he sellis the laif." "Item the 14 day of November anno 95, bocht in Medylburgh . . . 6 barellis of saip, ilk barrell cost 14s."

[‡] Jac. 6, parl. 4, c. 59.

[§] Jac. 4, parl. 6, c. 84.

In 96 "3 ton of waid, ilk ton 8li." "In Dysember anno 96 . . . bocht in Bery . . . and schepit . . . a kark of alom, cost 38s.," whilst "in Dysember anno 98 . . . a cark of alm cost 58s."

Under "Jhesus Anno 98, in Fewirzer" we find "a pip of wad, cost with the costis 3li. 15s. 10g."

A Scottish dyer had evidently visited Halyburton, because in 97 (October) he sends "Andro Elphynstonne to Aberdeen in Wyllykin Lychtharnes with And° Lytstar" some old French crowns.

In August 98 he sent to Andro Cullan "a bayll of madir weand 850 li. the C. cost 8s. 4g., ". . . bocht in Handwarp."

Under "Aprvll anno 99" there are two entries. "Item paid for 2 ball' of mader in Handwarp 13li. 2s. 8g.," and "Item for ij ton of waid 15li."

The prices paid for English white cloth and for scouring, dyeing and shearing the same, are given under "the 26 day off Jun anno 99 in Medylburgh" in an account with Alexander Lawder :—"Item paid for hym for the quarter off a stek of iij Ingill quhit . . . 2li. 10s. Item for redyn' of it or it was lyttit, ilk ell 6g., 11 ell 5s. 6d. Item for lettyn off iij ell rossat and viij ell of blak, ilk ell 12g. Item for scheryn eft(ir) the lyttin, ilk ell ijg. Item 3 ell off canvas to pak in, 9g. Som of thir 11 ell with costis 3li. 9s. 1g."

On the 10th of July 99 he "bocht in Medylburch . . . a pyp of waid, cost the furst bying 3li. 15s." and in October a "pyp of wad, cost . . . 3li. 15s.," for which the "oncostis" amounted to 10g., whilst in September 98 he "sald . . . a town of wald for 7li. 15s." A "pyp" seems therefore to have been equal to half a ton.

Woad had evidently become much cheaper in 1502, because Halyburton sold "a tone off vaid ffor to pay at Mech(el)mes in the Handwarp mercat for vij li."

In March of the same year we find the account for dyeing a piece of cloth red :—"Item lyttyt a stek of quhit of his, red, the quhilk cost 4g. the ell, haldand 35 ell." It was dyed in "Medylburgh."

The following are names and prices of some of the cloths imported and exported by Halyburton :—

11 ellis off claith, blak, price of the ell 17 sturis—Som 30s. 2g.

5 ell of Rowanis clath—1li.

Half a stek of bron cost—3li. 5s.

A stek gren chamlet—26s.

A stek tany—26s.

Paid in Handwarp for 11 ell' of Engllis clath for to mak his son a gon—4s. 8g.

The entry made in November 1496 shows that some loth called forrest cloth was sent from Scotland and sold n Holland :—"Item racauit . . . out of the samyn chip . . . a pak of (claith) forest. Item sald a stek her of in Brugis for 12 gret the ell, haldis 32 ellis. Som 2s. Item sald a othir stek for 9s. dossin, haldand 35. om of that stek, 26s. 3g. Item sald the ramanand to ornellis Classon for 5s. the (dozen), with 6 ellis to bat, aldis 57 dossyn ellis." From this we may conclude that he cloth, probably linen not woollen, must have been arse and that it had to be sold at a low price. Cloth alled "Scottis gray" was sold at about the same price.

A stek of Ryssyllis blak, cost 9li. 15s.

A stek of rownd holland 44 clath, cost 14g. elk ell. om 2li. 11s. 4g.

3 stekis of lynnyn clath, haldand 125 ellis, price of the l 6g. Som 3li. 2s. 6g.

6 stekis say, 3 red, 3 gren, cost 23s. the stek. Som 6li. 18s.

3 ellis cramysse sattyn, ilk ell cost 17s. Som 2li. 11s.

According to Maitland[13] the Fullers claimed that "the embers of this Company of Wakers, from a Petition esented to the Common Council of Edinburgh in the year 1500 (20th August), are of opinion that their Craft was incorporated before that Period ; nay very soon after the Foundation of the City." Maitland does not believe that a company had been formed at this early date but that possibly regulations existed for Masters and Journeymen of this Craft.

The following clauses in the Charter granted to the fullers are of interest :—"That each Member of the Company, before he begin Business on his own Account, be examined by four Masters of the Trade, concerning his Qualifications in his Art, to prevent People's being imposed on by ignorant Persons ; and if approved of, to pay the Sum of Five Crowns Scottish to the Corporation as upsett Money." In this we find a striking resemblance to the laws in Germany concerning apprentices in early times. "That each Person, at his entering on Business for himself, be worth three Pair of Sheets, and of Ability to pay for one Stock of white Cloth, whereby he might be in a Condition to make good Damages to those who imploy him." No mention being made of shearers in this clause, we may presume that the fuller also did the shearing whilst the term "one Stock," no doubt refers to milling stocks, *i.e.*, the fuller had to possess sufficient capital to pay, if necessary for the contents of one stock.

"Whatever Person of the Craft be found working with cards in the Country, shall, for every such Offence, forfeit the Sum of Fifteen Shillings Scottish Money, to be equally divided between the work of St. Giles' Church, the aforesaid Altar, and the Informer." Evidently fullers who were burgesses were not allowed to exercise their trade outside the burgh. "Working with cards" no doubt refers to the use of teasels.

"And as the County Wakers and Sheermen receive much Work from Edinburgh, without contributing to the great Expense . . . all Unfreemen who are imployed in this way, shall weekly pay one Penny each, towards the Support of the said Altar."

In Aberdeen, according to Bain,[7] "the litsters formed themselves into a society about as early as any other body of craftsmen in the town. In 1501 their Deacon was presented to the Council to be sworn, and to have his election confirmed ; but it does not appear that they ever applied for a Seal of Cause, as was done by the other crafts about this period. On the contrary the dyers seem to have held aloof from the rest of the craftsmen and at times claimed an equality with the merchant burgesses, an equality which however was never acknowledged by the merchants or craftsmen. When the question of procedure was rife at times of religious pageants, the litsters frequently claimed a superior place, but in 1546 they were definitely instructed to furnish their banner and take part in the Corpus Christi and Candlemas procession along with the rest of the craftsmen. On 25th June 1546 "the haill litstaris of this burgh chesit Alexander Fresser, litstar, their dekyne."

A statute regulating the order in which the craftsmen had to walk in the procession was given in 1501 (January 30th). The "flesseris" were first, the "barbouris" second, 11th came the "walcaris." 12th the "litstaris," 13th the "wobstaris," the procession finishing with the blacksmiths and hammermen. It was further ordained that "the craftismen sal furnys the Pageants ; the cordinaris, the Messing ; wobstaris and wolcaris, Symeon ; . . . the litstaris, the Emperor.

This order did not give satisfaction to the skinners. They rebelled and in a new regulation issued 28th May 1507 we find that "nixt thame the tailyoris, efter thame the vobstaris, valcaris and litstaris togidder." According to this new regulation the crafts had to furnish :—"Litstaris Sanct Nicholess wobstaris walcaris and bonet makaris Sanct John."

An important change in the character of these displays took place in 1508, when the Abbot and Prior gave place to "Robyne Huyd and Litile Johnne," but the order of precedence as regards the craftsmen remained the same.

The contribution paid by a craftsman to his craft was very small because we are informed that it consisted of "quarter pennies."

From a charter[13] granted to the Bonnet-Makers of Edinburgh on the 31st March, 1530, it appears that they were united with the Fraternity of "Wakers" and "Sheermen." "The Bonnet-Makers in Edinburgh by the great Use of Hats, were reduced to so low a Condition, that they were neither able to support their Families, or the Expense of their Company, without the assistance of another Trade being annexed to them; wherefore by Consent of the Fraternity of Litsters or Dyers, they applied to the Common Council of the City to have the said Craft united to them.*

The following paragraphs taken from the Charter granted are of interest:—"1). Incorporation of the Bonnet-Makers and the Litsters, Burgesses of this City." This is followed by elaborate instructions as regards the election of "Deacons," etc. "5). The Counsell, be thir Presents, in all Tyme comeing, prohibits and discharges all Litsters whatsomever, except the persons above named, who are Freemen Litsters of this Cittie, to exerce and profess the said Trade and Airt of litting and dyeing within this Cittie, unless they be admitted Freemen of the said Incorporation be the fore said Persones, present Litsters, and ther Successours that shall be lawfullie admitted Freemen of the said Incorporation, with Advice and Consent of the said Bonnet-Makers to take Tryall of the Sufficiencie of the Worke and Cullour dyed and litted by any of the intrant Freemen of the said Incorporation of the Litsters that shall heirafter be admitted, and to make Acts and Statuts amongst themselves for improveing of the said Airt, conforme to the foresaid Act of Parliament in favour of the Litsters."

That the Bonnet-Makers did not confine themselves to the making of bonnets only but that they also practised dyeing is shown in the following paragraph;—"6). It is stated and ordained conforme to the foresaid Agreement, that the Bonnet-Makers and ther Successors, shall in no Wayes incroach upon the Airt of litting of Cloathes and Stuffs, which is only proper to be dyed, litted and drest by the Litsters; and that non of the said Freemen Litsters, . . . shall medle with, nor incroach upon the making and dyeing of Bonnets, Nightcaps, or any other things that they bein in use to work and dye. . . ."

"7. The Council statuts and ordains, that, in no Tyme comeing, any Litster shall have Liberty to exerce the Airt of Litting and Dyeing within this Cittie or Priviledges therof, but such as are actuall Dyers and Litsters, Burgess of Edinburgh at present, or have been already bound Prentices, and are booked in the Dean of Gild's Books as Litsters; and those shall be obliged, before they can exerce ther Art, to byde Tryall as to ther Qualifications, before they be actually admitted to the Exercise of the said Airt. . . ."

"8. That no other Persones in any Tyme comeing are to be admitted Freemen of the said Incorporation, as Litsters, wer they never so weill qualified, unless they serve a Freeman Litster of the said Corporation for five years at leist . . . unless he be a Freeman's Son, or marie a Freeman's Daughter of the said Incorporation of Litsters." Provision was however made in the Charter so that merchants were not prevented from importing "any Cloaths, Stuffs, Stockings, or any other Wair in use to be dyed from any forraigne Cuntrie, of whatsomever Dye or Collour . . . or what else is in Use to be dyed or litted within this Kindom . . ."

"10. It is declared, that no Persone whatsomever, have Liberty to sett up a Lithouse in any of the Suburbs of the good Town . . . or exerce the said Airt of Litting or Dying. . . ."

Some further provision is made in 11, that people may send out cloth to be dyed and that they are allowed to bring it back into the citty "as they have been in use to do."

In 1540[6] [19]† an Act of Parliament was passed dealing with "Drawaris of Claithe," with dyers of false colours and with "Flaland Claith." "It is Statute and Ordainit anent drawers of claith and litstars of fals colours that in every borough there be a qualified man chosen to seal all cloth and he shall have for his labour of every steik seling XII d., and if any drawer of cloth be apprehended that one half to be our Sovereign Lord eschewed and the other half to the borough and the said drawer within borough for the first fault to tyne their freedom for year and day and for the second fault for ever and also of them outside the borough 'dingand calk cresche or flaland claith' that the same be eschewed and those holding to refund 'scait,' to the owners and if the said sealer be found culpable sealing insufficient coloured or 'drawin' cloth he to tyne his freedom and to be punished in his person and goods."

The drawing of cloth was no doubt a stretching operation in order to lengthen the cloth and to make the measurement more than it ought to be. In a poem, entitled "A Concise Poem on . . . Shepton Mallet,"* the various stages of the manufacture of woollen cloth are explained, the drawing of cloth is however described as mending of cloth which had been torn in the manufacture.

> "The Drawer last, that many faults doth hide
> (Whom merchant nor the weaver can abide)
> Yet is he one in most clothes stops more holes
> Then there be stairs to the top of Paul's."

Other illegal practices were apparently employed for thickening cloth, so as to make it appear of a better texture than it really possessed; they are mentioned in the same act under "dingand calk cresche or flaland (or cardand) claith." According to Jamieson,[19] dingand means beaten or knocked about; calk corresponds to chalk; cresche to greasy and flaland either beaten with a flail or some similar instrument or cardand the application of cards or teasels in order to improve the surface of the cloth. Whilst some of these expressions may be applied to the treatment which woollen piece goods may have undergone, it might also be suggested that flaland and calk had reference to the treatment of linen cloth. A picture of a bleach field, in the Encyclopédie Méthodique, Diderot and d'Alembert (1791), clearly shows men in the act of beating rolls of linen cloth with a kind of flail, prior to washing it in the river. This was no doubt done in order to remove impurities, and may have been the forerunner of the washing stocks.

The Edinburgh Records[12]† show that in 1546 John Gaittis, an Englishman, obtained a licence to "brew saip," but he was only allowed to sell it to freemen of the borough and in wholesale. Regulations were also issued‡ in the same year for the manner in which strangers should sell to freemen of the town:—"Silkis and claytb to be sawld in haill steiks . . . item mader to be sawld in polks: item allum to be sawld in cark. . . ."

In 1552 an Act of Parliament[14] was passed limiting the number of coloured cloths to "scarlet, red, crimson, murray, pink, brown, black, green, yellow, orange, tawny, russet, marble, grey, sadnew colour, asemer, watchett, sheep's colour, lion colour, motley, or iron grey." In the reign of William and Mary, the list was extended by the following additions:—Violet, azure, friar's grey, crane, purple, and old medley.

In order to defend the city in 1558[13]§ the Crafts of Edinburgh each agreed to furnish a number of men among these the weavers sent 13 masters and 13 men, the walkers 28 masters and 15 men.

In 1564[13] the litsters and weavers were again accuse of fraudulent practices. "The Litsters, in Conjunctio with the Weavers and Wakers, having committed grea Frauds in their respective Occupations, to the grea Hurt, and almost Ruin of the Woolen Manufactures. New Regulations were, therefore, issued by the Tow Council of Edinburgh. "The Litsters of this Citi . . . voluntarily appeared before the said Council, and gave an undertaking to act in accordance wit the regulations,‖ an abstract of which follows:—"Th thay now nane of thame, in ony Tyme cuming, sall lit ony manner of Cullor of *Muster de Villois*, French Gray, or Russatis, with Brissell or Ursell, nor lit ony Blakis with Cuppruss, Gallis, Allerbarkis, or sicklike fals Cullors, bot the samyn to be littit with Mader, Alme, Glew, and sic trew Cullors as has bene, and is usit amongis Men of Honestie, Experience, and gude Concience of the said Craft, under the Pane of Five Pund for the first Falt, Ten Pund the next Falt, to be disponit to the common Workis; and, the third and last Falt, to be baneist the Toun and Fredome thairof for ever. And sa oft as sall happin ony of the saidis Littisteris or utheris of that Occupatioun, or taking that Craft upon thame, to spill in thair Defalt, the Claith or Woole gevin the thame to lit, to pay to the Awiner the uttermaist Availl and Pryce that the samyn wald gif, in cace it wer perfitelie, compleitlie and sufficientlie wroucht and littit, provyding the spilt Claith and Woll be gevin to the Littisteris Spillaris thairof, the uttermost Availl, as said is, beand payit."

* By Richard Watts; printed in The Young Man's Looki Glass, in 1641. English Industries in the Middle Ages. Sa mann.
† II., 205.
‡ II., 125.
§ Counc. Reg. f. 132, 10th June.
‖ Counc. Reg., Vol. IV., f. 114.

The next paragraph deals with the stamping of dyed cloth:—"that thair be made ane Stamp, and the Tounis Arms thairupon, quhilks sall be given in keiping to ane honest, trew sworne Nichtboure, of Experience in making and colouring of Claith." The Stamper had to stamp each piece of cloth made in the burgh, and for his trouble he received "twa Pennies allanerlie" for each piece.

The "Stamp-keiper" had to be ready at all times to stamp the cloth, "and gif it happyns the said Stamp-keiper to stamp ony Maner of Claith, not sufficiently coucrit, to pay Five Pund for everie Falt. . . . and to be puneist in his Bodie at the Will and Plesoure of the Provost, Baillies and Counsale for the Tyme. And farder, That na Maner of Man no Woman within this Burgh, take upoune thame the Occupatioun of Litting bot sic as be Burgesses and Fremen and before their Admissioun, that they mak thair Assay of Colouris, and deliver the samyn to the Provost . . . of this Burgh, and thay to call in before thame the honest Nichtboures, with the said Oversear, and tak thair Jugement of the Wordyness of the said Assaygevar, and of the Justnes of the Coloure, under the Pane of baneishing of the Toun."

The law made in 1457[6*] "Lit to be cried up and used as before," and the "article for exporting and importing country lit," were remitted to a commission in 1567[6†] and in 1581[6‡].

On the 23rd September, 1569[2], when the guilds had to elect their new "Counsale for the Yeir to cum," we find that the occupation of the dyer was still considered a "rude" one, because "na cordineris nor littistaris, nor vtheris of sic rude occupatioun, aucht to be vpon the counsale."[§]

A curious complaint[1] was made at Holyrood House on the 13th of February, 1581, by Claude le Liernero, Fader Persone-Petir Bursier, Stevin Solge, merchandis of Pareis, Peter Thomas and other merchants:—"The personis abouewritten having laidnit at Burdeaux, in the moneth of Maii last wes, the nowmer of ane thowsand ane hundreth and foure scoir ballis of waid, . . . in the schippis callit Esperance of Oleron (and others) . . . to have bene transportit to the partis of Rowan in France, Antwerp and Middleburgh in Flandirs and Zeland, the said schippis were interceptit in the way be certane Scottis pyrattis . . . and brocht in be thame to the raid of Kirkcudbricht, quhair they sauld and disponit the saidis guidis, for the maist part, to the liegis of this realme . . . the said James Craig . . . was sent for recoverie of the said waid." He recovered however only "to the nowmer of thre hundreth and fiftie bollis waid."

The following regulations as regards apprentices were issued in Edinburgh in 1583:[13] "If any Man be an Prenteis heirefter, and not put in the said Buik, his Prenteiship sall be to him of nae Effect. Alswa, be reasone evrie Industrie is not of lyk Valour and Substance, it is declairit, what ilk Rank or Degrie of Prenteisses sall pay." It is here stated that there were fourteen Crafts, and among these "The Prenteis to an Wobster, Waker . . ." had to pay "at his Entrie, Ten Shillings, and for his Upsett, Fyftie Shillings."

In the year 1587 the "Act in favour of the craftismen flemygis was passed."[6*] "That is to say the said craftismen sall remane w^{t}in this realme for the space of fyve yeiris at the leist after the dait heirof and salbring within this realme the nowmer of XXX personis of wabsteris walkaris and sic vtheris as may wirk and pforme the said work as alsua ane litstair or mafor litting and pertitting of their said warkis and . . . Sall mak and pfite ye steikis and peeces of warkis according as the samin ar or hes bene maid in flanderis holland or Ingland kepand lenth breid and fynes conform to the rule."

In the same year an act was also passed for "regulation of Flemish wobsters, waulkers, and litsters and the appointment of an overseer of their work,"[6†] and in 1597[6‡] it was forbidden to bring any more craftsmen into the country for the working of wool.

The importation of English cloth was considered the cause of the unemployment of women, and in order to remedy this the Convention of Burghs prohibited in 1578 the import of such cloth[§]:—"Because the samyn is ane greit hurt to the realme, and is the occasion of mony vagabund wemen to pas ydill thairin for laik of woll, laubouring and making of clayth."

This prohibition was endorsed in 1597[12] in the following words:—"The same claith haveand onlie for the maist parte ane outwarde shaw, wantand the substance and strenth quhylk oftymes it appeiris to have."[∥]

in dyeing during the period extending from 1580 to 1618.

"The Inventair of the guidis and geir deliverit furth of the schip callit the Thomas of Dundee[8] (August 1591)" enumerates all the materials which the ship contained, and among these we find:—"ane barrell, with ane punsioun of mader, all weyand, with treis pokis and towis, ii^{c}lxxxxiiii stane Scottis wecht." Then follows a statement that many of the goods had been spoiled by water and were, therefore, sold by auction. The madder contained in the said inventory "being watt with sey watter, wes thocht to be in point of tinsaill, . . . the said provost, bailies, and council had caused Patrik Durhame, and William Newtoun, 'listaris,' burgesses of the said burgh, to value the same: who had declared upon their conscience that the same could be of no use for their occupation, and therefore they could not say what it was worth."

Another ship with a cargo of madder gave cause for the following complaint[1]:—"Anthony Briegers master of the ship 'The Great Jonas of Dantzig' complained about goods belonging to Ferdinand Grand Duke of Tuscany having been taken from his ship when it was driven by stress of weather into the harbour of Gritingue Viage in Shetland in the spring of 1591; the ship was boarded by Jarmirus Unfreii, governor of the island and others and they demanded in the king's name a surrender of all the 'papistical' goods."

From a detailed account[12] given by Fynes Moryson, a student of Peterhouse, in 1598, it is seen that the quality of cloth made in Scotland at the time was poor, because he informs us that "the Eastern Scots carry into France coarse cloathes both linnen and woollen, which be narrow and shrinkle in the wetting."

The Shipping List of Dundee[17] provides another source from which valuable information may be obtained as regards the imports into Scotland of materials employed

In order to present the matter in a concise form, in case each only the date of the arrival of the ship and that special part of the cargo which is germain to our subject, will be given.

"Sexto Decembris Anno D^{ni} 1580 . . . fra flanders ane ball of mader."

"Nono die mensis Januarij 1580 . . . fra burdeaux conteanand fyftie aucht twnnis . . . vad"

"Undecimo Jenuarij 1580 . . . fra burdeaux . . . thrie scoir and thrie twnnis and ane half . . . waid."

[∥] Acts IV., 119.

In January, February and March of 1583 "maldir, malder, mader, vaid, and waid" are again among the goods imported.

The cargo of a ship coming from "Danskene" in August 1588 contained dyestuffs and dyed linen:— "v lastis lit . . . xvj lastis lit lynt . . . xv lastis lit for lynt."

In January 1588 a large quantity of waid and a small quantity of "maydr" and in February a special kind of woad under the name of "sma waid" are imported whilst in March and then up to December 1589 we find numerous entries of "gaid."

The second volume of the Shipping List begins in March, 1612 and imports of woad under the name of "wayid" are found frequently up to 1614.

The cargo of a ship which arrived in May, 1614, is of special interest because it contains alum, Brazil wood, starch, madder and soap:—"tua bailes of mader . . . thrie twne of alme . . . tua hundreth wecht brissell . . . tua last of seip . . . ane trie of stiffeng."

An old account book in which the entries extend over the period between 1587 and 1630 "The Compt Buik of David Wedderburne Merchant of Dundee,"[17] is another source of valuable information. The following extracts have been taken from it. On one occasion Wedderburne sent cloth to Rouen to be dyed "fyn scarlit to be my lassis weylecottiz." In February, 1591, a commission was given to Peter Man to sell one last of herring and to expend the money received "on lynt hattis with veluit about the browis on 2 stikis fusteonis of trym collouris and the remanent on stainings." On May 7th, 1610, "Send with Alexander Broun teylzeour to Londoun xij ellis narrow blew clayth Item 7 ellis bred blew clayth thikit to be littit violat And hes send with him 19 spynellis of yarn lyning Ilk spynell cost me 28s. to sell it and to pay the lit." An account for bleaching of linen is entered under "Primo June 94 Send with William Ker of Rossy four /do/small lyning to bleitsche. Item /2/ Tuilden to bleitsche receavit. . . . Item xv ellis smal lyning to bleitsche All markit with netteis mark. Item 24 elnis eln bred smal lyning markit all blak silk with red silk to bleitsche except ane with red," and on 12th January, 1614, "Send with Alison to Bleitsche in Petkerro Item xxij ells lyning to bleitsche payit Issobell Cokburn 3 lib. thair for . . . Item the sarkis yit bleitsching receavit and payit 8s. therfor."

As regards prices paid for dyeing wool we find the following entries:—"xv August 91 Receavit . . . Item x s. Item v lib. Item vj lib. xvj s. ij d. for woll litting is 7^{xx} 18 lib. ij d. Item receavit 30 d. restis xx lib and I am awin yow for half a stane of woll litting quhilk I have payit . . ." "3 October 1591 All the former obligatione payit and all thingis comptit betwix us allowit and payit Except xx lib quhilk the said Henry is awin me and I awin him for the litting of half a stane blew woll litting."

The name of a dyer is mentioned under "xxv February 96. All comptis betwix David Melvill litster and me is comptit and all payit and I gef him a pynt of wyn."

Another reference to a dyer and dyeing is found under December 7, 96, when Wedderburne gave "James Lindsay litster 5lib. . . . David Melvill a promes to lit for wryttis at Witsonday nixt. . . . David Melvill lit conforme to his present and lvj lib." From the foregoing we may take it that Wedderburne not only sent the cloth to be dyed but he also supplied Melvill the dyer with the necessary dyestuffs.

Scotch linen cloth was exported to Spain on 3rd of October. The quantity was however small, amounting to about 113 "ellis" usually "eln bred," the prices ranging from 7s. to 24s. "the eln." In addition 42 yards of "half lyning" at from 5s. to 6s. 8d. per yard. The latter material probably consisted of linen and wool or hemp.

Although the accounts prove beyond doubt that some of the cloth was dyed in Scotland, special colours, for the dyeing of which high prices had to be paid, were sent to France. Thus on the 21st December, 1613, were sent "with Robert Auchinlek to Deip or Rwen 4 ellis 6 quarter bred blew clayth to be Littit of a said and grave cullour the exemple I pressit it on his commissione and hes gifin him xij s stirling to pay thairfor."

It seems rather curious that the pieces sent had already been dyed blue and one may, therefore, presume that the Scottish dyer was unable to obtain the particular shade required.

On August 20th, 1590, another quantity of linen cloth, both bleached and unbleached, was sent abroad and instructions were given to buy for half the money received for it "gude vaid and to be send hame on the Falcon Or utherwayis gif be cum hame the hie way Haill on vaid of the best sort $4^{xx}7$ lib. 12s."

Cloth to be dyed scarlet was sent to London in 1621, "with James Annand in Dauid Corfittis crear to London 4 ellis a half sewin quarter bred quhit clayth to littit to be my wyf and Magdalen Weyllcottis skarlett."

A few of the many entries of prices of woollen and linen cloths which Wedderburne bought in fairly large quantities and which he retailed in Scotland will show the cost of these articles:—bred clayth . . . 9s. 6d. the eln; narrow clayth . . . 4s. 3d. the eln; small lyning . . . 6s. the eln.

The Trades House of Glasgow, established in 1605, consisted of 56 members, and was composed of the deacon-convener and collector, with deputies from each of the fourteen incorporated trades; the dyers at that time being still joined to the bonnet-makers. Whilst the weavers had the right to send four representatives, the Bonnet-makers and dyers were only allowed to send two.[18]

In "The Letter of Gildry" given "At the Burgh of Glasgow, the 6th Feb. 1605 years" it is stated in Clause 24 that "it shall not be leasome to a single burgess, who enters hereafter, to be burgess, and becomes not a gild-brother, to tapp any silk, or silk-work, . . . no lawns or cambricks, nor stuffs above twenty shillings per ell. . . . not to tapp hemp . . . waid, grain, indego, nor any other kind of litt."[18]

In the same year King James VI. threatened to take the control of the Flemish weavers out of the hands of the burghs. The burghs preferred to live "cheifly by thair negotiatioun," *i.e.* by trading, and they went so far as to assert that they had suffered loss by the manufacture of cloth.[12]

The following entry under "6 Aprilie anno Domini 1610" in the "Liber Secrety Sigeley,"[3] refers to the import of indigo, azure, starch and soap, and in it encouragement is given to the manufacture of these articles in Scotland. "Ane letter maid making mention that oure souvrane lord considderung the gret sommes of money that from tyme to tyme are wasted bestowed upon Indigo and Azure to mix or stiffing and upon soap for washing of cloathis within his highness kingdome of Scotland which being brocht from forane nations are sold to the Lieges at gret rates and pryces albeit their mecht be als good (or rather better) made within the same and sold cheaper. Therefore his majesty having due regard to the common wealth of the said realm proffitt and comodity of the Lieges within the same ordaineth a letter . . . to Johno Nasmyth Chyrurgino to his majesty, granting to him by himself his servants and others in his name full liberty and privilege to make and cause to be made the said Indigo and azure, hard and soft and soaps for washing of cloaths of such colours and quantities as they shall hold fit and expedient and to sell the same at there pleasure in time coming during the whole space years and terms of 21 years next after the date hereof with power to the said Johno Nasmyth and his foresaids during the said space in case they shall happen to make more of the said Indigo, Azure and Soap than may conveniently serve his highness lieges to carry and transport the same out of the kingdom . . . during the space of all making of the said soap, azure and indigo hard or soft of any colour." In the manuscript the "hard and soft" refers to indigo, whilst it would naturally suggest itself as referring to the manufacture of soap.

Dyed English cloth was frequently smuggled into the country. On March 15th, 1609, the searchers found anc seized " within a chalmer of the dwelling house of Stewart . . . threttenen wobis of Inglishe cloath of divers collouris."[1]

Among " the goods broeht in within the burgh of Ayr betwix 1617 and 1621 "[2] we find " Imported from Flanderis in the ' Flower da lice ' of Ayr . . . from Campveir in the ' Gift of God ' . . . lit (new lit and orchard lit)," whilst in the Customs on imports on the south side of the Forth, " brissel," alum and " blue medoun veyade " are mentioned.

Innes[2] informs us that Customs tables, such as the Assisa de Tolloneis and the Chapters de Custuma Portuum* existed in the twelfth century. A table which however is more complete was decided upon in a Convention of Estates held at Dundee in May 1597. The prices given in these tables are of secondary value only, but they give us complete information as regards the articles of commerce in that time. The tables are entitled " Inuarde Custumes The Waluatioun and prices of mechandries broeht within this realme Quhairof xij d. for ilk Pund of the price thairof suld be taken wp in name of custume. 22. Maij 1597." Among tho articles enumerated we find :—

Brissell the j^{c} wecht thairof	xv li.
Claith serg and steming the eln thairof	v li.
Stiffine callit Amedoue the stane thairof ..	xl s.

A much more compelete list of articles of import and export is however given in the Tariff or Table of Rates of Custom, and Valuation of Merchandises, settled by Royal Warrant, in 1612.[2] Among the exports are found articles such as Brazil wood. From this we must conclude that many of the export duties are rather transit dues and not common customs of export. Some idea of the number of entries may be formed when it is stated that 220 different medicinal and chemical substances, among which " Mummia " is naturally not absent, are mentioned The following is a list of a few of the articles of interest :— The customs to be paid are fixed at " tuelf pennys for every pundis worth," but as regards the valuation of the different articles it is difficult to say definitely as to whether it is in pounds Scots or Sterling.

Of the great variety of cloths only a few can be mentioned here :—

	Bottanos or pecels of linning litted blew the peice	xl s.
Buckram	of Germany . . . the peice	iii li.
	of Frenche making the dozen peces	xviii li.
	Calico copboord claithis the peice	xl s.
	Claith of the seall, searge of Florens, claith of John Nicoll and counter tute searge of Florens the eln	v li.
Clothe	skarlett cloth the eln	x li.
of	Broad English claith the eln	vi li.
woll	Deushire carsages the peice	xxiiii li.
called	Peonystone freise the eln	xl s.
	Cottoun freise the eln	xx s.
	Kelt callit Kendal Kelt the eln	xiiis. iiii d.

Among " Fusteans " are found :—

Amsterdame Hollaod or Dutch 15 ells	xvi li.
Barremillanes Milan Culen and weazell the peice	xvi li.
Jeanes the peice	lx li.
Naples fusteanes tripe or velure plane 15 ells	xx li.
Groganes called Lilles worsett and moccadoes the narrow peice	xli li.

Other kinds came from England and from Flanders.

In addition to the above, thirty-nine different kinds of linen cloth are rated, such as :—

Canves 100 elnis	l^{c}xx
Spruce xxviii elnis	vi li.
Callicoe fyne the peice	vi li.
Cambrick 13 ells	xl li.
Lawnes 12 ells	xl li.
Damask, Boord clothing of Holland the eln	iiii li., etc.

" Claith of the seal " no doubt denotes that the cloth had been dyed in fast colours and we find only in the case of " Veluotts " made of silk another reference to fast and loose colours.

" Veluotts "—of all collouris oute of grane the elln	x li.
Right crymosine or purple in grayne the elne	xvi li.
Figored of all collouris out of grayne the elne	x li.
Figored ryght crymosin or purple in grayne the eln	xvi li.
Cloth called wollen cloth and plading of Scottish making the eln	xx s.

Compared with the list of imports, that of the exports is very small. Under cloth there is only one entry :—

Wollen hois maid in Leith wynd and other places of this kingdom 1^{c}	iii li.
Worset hois the hundreth	l^{c} lxxx li.
Sayes of Scottish making the peice	iiii li.
Woll caryed out of the cuntrey vpoun licence the stane weght	vi li. xiii s. iiiid.
Yarne called Scottis linning yaroe transportit vpoun liceoce the hundreth weght	lxxx li.

In 1617[1] Johnne Hammiltoun, " littistair in the Cowgait," was convicted for shooting. James Hereot, " litster," burgess of Edinburgh, is mentioned in connection with a suit against Sir James Home of Broxmouth, knight, who owed the dyer some money; and Patrik Broun, assisted by Johnne Wilsoun, littistair in Haddingtoun, rescued a rebel and " conveyit him in at ane chalmer and oute at ane back dure." In 1620, Alexander Findlater, " littister," was convicted for assault. These facts are mentioned in order to show that all the names of these dyers are of Scottish origin, in contradistinction to the fact that at a similar period in England most of the names of dyers are of foreign origin.

Charles I. in 1619 granted privileges to Nathaniel Udwart for a soap manufactory at Leith*, and in 1621[1] (4th July, Edinburgh) at a Meeting of the Committee of Council it is stated with regard to the soap made at Leith " anent the soape maid be Mr. Nathanaell Uddart, and having fund his greene soape to be as goode and sufficient as the soape of that kynd broght frome Flanderis, . . . the baillis of Edinburgh " shall try the soap twice or three times a year. Black soap being evidently employed at the time in bleach works, Udwart is advised to manufacture this also :—" Anhairas it hes bene objectit aganis the restrante of importatioun of foreyne soape that in some pairtis of the West Cuntrey, especiallie abonte Loichquhinyeaugh [Lochwinnock], the blaitcheing of cloathe is commonelie maid with blak soape."

Bremner[14] informs us that the earliest indication of the manufacture of wool in Galashiels occurs in a charter, dated 1622. In it we find "waulkmills" mentioned. The population numbered about 400, the bulk of the people were "mailin' men" of whom probably enough enjoined to their labour on their "crofts" the arts of dyeing and weaving the produce of the cottagers' spinning wheel.

* Acta Parl. Scot., Vol. I., and Preface.

* The Domestic Annals of Scotland, R. Chalmers, Vol. I, p. 510.

I think it is safe to presume that the question of water pollution by dye-house effluents received serious consideration for the first time in Aberdeen in June 1632[1]*. "Anent the supplication presentit to the Lords of Secreit Counsell be the provest, bailleis and counsell of the burgh of Aberdein makand mentioun, that where they having takin to thair consideratioun the great necessittie wherein thair toun stood throw want of pure and cleane water and how that the water wherewith thair toun wes served come from ane little loche at the side of thair toun whilk is so filthie defyled and corrupted not onelie by gutters daylie running in the loches but alsua by the litsters who washe all thair cloathes in the said loche . . ."

The Burgh Records of Peebles (272) inform us that in 1633 the Magistrates of Peebles, anticipating the policy of the trustees of the linen manufacture nearly a century later, resolved to have spinning regularly taught to children of burgesses by a qualified mistress,[16] and in 1641[6]† an Act set forth :—"In every shire a school to be erected, to which each Parish shall send one or more boys to be apprenticed for seven years to learn cloth making." These may be considered as the first attempts to establish technical schools for spinning and weaving in Scotland.

The shrinking of linen cloth in bleaching caused the passing of an Act of Parliament in 1641[6] (Caroli I.). "Lining cloth is become ane of the pryme commodities of this kingdome whereby many people are put to worke and money is brought within the same Wich pairtly throughe the deceet vsed by the bleicheres in lymeing therof and pairtly by the uncertanties of the breadth Is lyklie to come in contempt abroade to the great prejudice of this kingdome . . . no makeres of Lining cloath nor no otheres whatsoever present to merket . . . make or sell any lining cloath of the pryce of ten shillingis the elne or above of les breadeth than ane elne."

The following Acts of Parliament indicate the strong desire on the part of the Government of Scotland to establish and to foster the dyeing industry.

1641.[4] (c. 100. v. 412) Litsters wares may be imported custom free for fifteen years by those who erect manufactories.

1641.[4] (c. 272. VII. 252) 3 oz. of bullion silver xiid. fyne to be brought to the mint for each cwt. of indigo exported.

1661[4]. (c. 272. VII. 253) 2 oz. of bullion to be brought to the mint for each cwt. of new lit exported, 2 oz. of bullion to be brought to the mint for each cwt. of madder exported and 2 oz. for each 3 cwt. of fat madder exported.

1663[6]. (c. 52. VII. 485) Individuals or societies establishing manufactories are empowered to seize beggars, vagabonds and idle persons, and employ them in their works.

1669[6] (VII. 560 a) Every thousand weight of madder imported to be liable in 5 oz. bullion as custom.

In 1672[4] (c. 5. VIII. 63 b) "the wholesale trade and the importation of wald" and other materials for dyeing was confined to the royal burghs, and in the same year[6] (VIII. App. 23 b.) James Lockhart of Cleghorne petitioned for liberty to establish a manufactory of alum.

A recommendation to the Magistrates of Edinburgh, to incorporate the dyers with some other trade, or else to make them an incorporation by themselves, was made in 1681[4]‡, and issued as "Act of Recommendation in favor of the Litsters of Edinburgh," as follows :—"a Petition by William Phin and John Smibert for themselves and in name and behalf of the haill Litsters freemen Burgesses within the Burgh of Edinburgh . . . petitioners having been at a very great and considerable expense in setting up of work-houses ffats presses and other requisite for the due and perfect exercise of their trade of Litting, and having attained to that perfection in their Trade that all Colours asweill plaine as ingrained are dyed, and the Cloath and Stuffs pressed and stamped asweill by them as they are or can be either in England ffrance or Holland Nevertheless the Petitioners are exceedingly discouraged and prejudged by severall ignorant persons, who without due knowledge or experience of the said Trade, take upon them to keep privat Litthouses And who doe lykways abuse the Leiges by insufficient work and Collours which doe immediately cast and staine." They pray to either include them "with some Incorporations or Deaconries of Trade or Grant them privilege to meet amongst themselves."

In "The Account Book of Sir John Foulis of Ravelston," which covers the period from 1671 to 1707*, reference is made to fulling mills under May 5, 1703 :—"receaved of the walkers of ye wester milne ther 1701 yeirs rent 100$^{\text{mks}}$, by Jannie Gray ;" further under June 13, 1705 :—"I have cleared w$^{\text{t}}$ deacon Crysticson for the 3 yeirs tack-dewtie of the westerwakmilne," and finally under 1 July, 1706 :—"walkers of the east wakmilne, 3 yeirs rent for s$^{\text{d}}$ milne to whits."

In 1641 an Act of Parliament[6] was passed to encourage the production of fine cloth† and factories were started at Bonnington, Ayr and New Mills near Haddington. None of these undertakings seems to have flourished, because skilled labour was difficult to obtain. In 1681, the Duke of York, afterwards James II., visited Scotland, and in order to encourage the Scottish industries the Privy Council[6]‡ prohibited the importation and wearing of foreign manufactured goods. The Duke of York favoured a plan of establishing a manufactury for the production of fine cloth, and he "invited and encouraged" the undertakers, some of whom were Englishmen of substance.[16]

This resulted in the foundation of the "Scottish Cloth Manufactory," at New Mills, on May 10th, 1681. The chief promoters of the Company were Robert Blackwood, an Edinburgh merchant who was afterwards Master of the Merchant Company, and Sir James Stanfield. The latter had acquired property near Haddington, then known as Newmills (now Amisfield), which formerl belonged to the local monastery. He leased to th Company his fulling mills, office-houses, etc. Som valuable information as regards cost of production materials used and the management of the Compan has been obtained from documents found amongst paper relating to the estate of Sir James Stanfield, and furth from the minutes of the "managers," the first part which extends from 1681 to 1691, the second part fro 1701 to June, 1703. These have been edited by W. Scott for the Scottish History Society, from which public tion the following abstracts have been taken.[16]

The Company was managed by five officials call "managers," corresponding to modern directors, t chairman was known as the "praeses" and the manag of the works as "master." The people of Scotla soon expressed doubt as regards the wisdom of prohibiti the import of manufactured articles, especially when it w found that all the skilled labour had to be imported higher wages than those ruling in England. Against t it was urged that in order to sell home-made broad cl eventually as cheaply as that made abroad, patrio Scotsmen should be content with a cloth "a little d at first," owing to the great cost of "importing looms a procuring foreign workmen, besides the many losses a inconveniences attending beginners."

Whilst in October, 1681, only two looms were in ope tion at New Mills, the number had increased to 27 1683, and the manufacture of fine cloth had by t time been firmly established. Military uniforms w then beginning to come into vogue in Scotland. reason for this was very quaintly given in the follow words :—"In order to distinguish sojers from other skulking and vagrant persons."*

The Company made every effort to secure the Government contracts, but the price demanded was much higher than had to be paid for English cloth; the Government, therefore, gave special licences for the importation of cloth from England. Later on, the Company however had practically a monopoly of supplying cloth for the Army. In 1704 the export of wool from Scotland was again permitted, and when, after the *Union*, cloth was again freely imported into Scotland, some of the early manufacturers turned their attention to the production of inferior cloth. The New Mills Company however does not seem to have adapted itself to the changed circumstances, and it was, therefore, wound up in 1713.

In "Documents relating to the Foundation of the Company" we find a particular account of the workpeople and necessary servants employed in a cloath Manufactory to keep 20 broad looms at work :—

	Per diem. Men.	lib. 2 per week is	Scotts lib. s. d.
For the dye house and mylne	8 : 0		16 : 0 : 0
To a large new copper and a smaller for dyeing the wooll estimat			500 : 0 : 0
To ane additional tenter for watring and dyeing the cloath			80 : 0 : 0
Charges computed for oyll dying stuff and Allicant soap 9 llb. weight on each part cloath 332 peeces is			2988 : 0 : 0

In the minutes (5) it is stated that "George Home being ordered to look for a copper for dyeing, reports that the copper he was ordered to inspect ryses in the bottome, and for deying it must be other wayes." This being evidently unsatisfactory, Samuell McCleland and Hugh Blair are appointed "to try whatt a copper kettle will stand the pound weight in Holland, and to enquire here also how soon the two kettles could be made." But the price must have been too high, because (11) "as to the kettle its found considering the charges that it is best to cause make itt heire, butt yett the said person to try againe, and however, to delay the makeing till the master come." The order for making it is definitely given on July 15th, 1681, (12) "Immediately to cause be made ready one copper of sixty gallon and one of thirty gallon and send them out. Two dying fatts, each of them to be six foot high quhere of one to be made with one lead bottom quhich a plummer is to make befor itt be bound with timber, the other to be made by the wright att New Mills. (13) For makeing these fatts is to be provided 10 wainscot of 10 foot in lenth; its to be considered thatt the fatts are to be 3 inches thick. (14) Ane pomp of 11 foot long to be provided att Lieth, and sent to New-Millns, for conveying water to the copers and fatts."

On August 15th, 1681, instructions were given that "the dyhouse must be presently finished, that if the Lady and John Angly will not consent to give us in the brew house in place of the inlardgement conditioned then that presently the inlargeing of itt to the 28 foot in lenth to be sett about, and if John Angly want money, that money be advanced on his recept thatt lights be made in itt."

That dyeing must have been considered a fairly simple operation by the directors is shown in a minute of August 24th, that "it is to be considered what way blacks and reds may be dyed to save the charge of mentaineing a dyer."

The work produced by the dyer having evidently been of an unsatisfactory nature, it was "ordered that directions be given to the master that care be taken that the next reds be a better brighter color."

John Angly was written to on October 13, "to flagg the dyehouser" and instructions were given "to try whatt a blew fatt can be made for 3½ inches thick in the staffes, 5½ foot deep, 5 foot brood in the bottom, 4 foot brod in the top."

On the 26th we first find mention of the dyer. "Agreed with Robertt Young to goe out to New-Millns and make the blew fatt, we are to furnish all timber and he is to have dayes wages as John Gibson dyer payes him and he is make her sufficient work."

The first entry as regards materials used in dyeing is found under November 23 :—"it is ordered Mr. Robert Blackwood with the first write to Gawin Lowrie anent the shoe-mack," an order being given at the same time that "the master dey all Mr. Blackwoods stockens at 2s. sterling." On December 30, instructions were given "to write to London or Holland for oyle, tessels, argell, mather and shoe mack," and on January 4, 1682, "to London for 200 lb. weight famiconnidigo . . . and 100 more of Argall from Holland." At a later date we find an order for Jamaica Indigo, and presumably "famiconnidigo" means the same.

On November 15th, there is an entry *re* some cloth of "Robert Blackwood haveing had five ells dyed at New-Millns quhich he complains of as being damnified in the deying . . . they ordaine him get back his cloth without paying any thing for dyeing."

The dyer had evidently not been successful in dyeing silk in colours, because on December 13, 1682, it was "ordered thatt the next parcell of silk be all dyed att London except what is for black quhich is alsoe to be boyled off there as well as can be."

Amongst other materials, the following are ordered for the dyehouse on February 27, 1683 :—"500 weight of fastick, one hogshead of galls, 100 of compeach wood to be bought here 200 weight matter."

That both loose wool and pieces were dyed at the time is shown in another minute of the same date :—"Mr. Spurrway present is advysed to forbear mixing ony stone grayes for ane months tyme," and he is also "ordered to put in hand as much Spanish wool as be six peeces of cloath for black or scarlett."

The names of two other dyers are mentioned in the minutes of March 29th, 1683, in which some of the directors are asked "to agree with James Lamb anent the dyeing the scarlet cloth" and "to give Prescook dyer two dozen of silk stockens to dye black and are content to give ten pence sterling per pair for the dyeing them."

The price charged for dyeing scarlet was about 4s. 2d. per pound (325) "to pay James Lamb fyfety shilling Scotts for each pound weight deying scarlet cloath."

The minutes of 18th July, 1683, contain some interesting information as regards "ane accompt of the expense and pryce of the severall cloath mad at the manufactorie." According to this, four kinds of cloth were made, "a super fain cloath all Spanish, . . . the secund sort Spanish half Inglish, . . . the threed all Inglish, . . . the fourt sort of common mixtours and whyt." These cloths differed from each other chiefly with regard to the kind of wool used, and it will, therefore, be sufficient to give one of these accounts, the values being in £ s. d. sterling.

"A super fain cloath all Spanish costs as followeth :—

70lbs. fult Spanish wooll cost 26d. per pundis	7	11	8
For scuring and daying at 3d. per lb.	0	17	6
For spinning rekoning 67 lb. at 10d. per lb.	2	15	10
For piking scribbling and oyll 4d. per pund	1	6	3
For warping boboning 2s. 6d. for listing 1s. 6d.	0	4	0
For weveing 46 ell row at 12d. per ell	2	6	0
For burlling 12s. for woking and sop 6s. for dressing and finnishing	2	18	0
For wast and cords and wheills	0	03	0
For proportion of selleries	1	05	1
	19	07	7

This pis will hold at leest 27 ell and will stand 14s. 4d. per ell."

The charges for dyeing and scouring are certainly very low. In this case probably the loose wool was dyed and used in mixtures with white for greys or other colours.

Another charge for dyeing piece goods is also remarkably low (363): "to deliver to Galloway whyts Carthcart, dayer at Leith, to be dayed and dressed at 3s. 10d. Scots per ell."

The managers discovered that the cost of dyeing had been calculated too low, because on the 13th of May, 1684, it is "ordered that heirafter the mester deliver noe dying stuffs to the dyer for cloath untill it be first entered in the book, and that Mr. Marr may not forgett that at every time a not be given him therof shewing it is for dying cloath that we may know what the dyeing of every ell of cloath stands us . . . and what is given out for dying of wooll James Marr may have a tickit therof that the concerned may know how the dying stuff is consumed."

---

* Rec. Privy Counc., quoted by Chambers, Domestic Annals of Scotland, Vol. II. p. 419.

Both silk and worsted stockings were made at New Mills, and from two entries (465 and 467) some information is obtained as regards the different shades which had to be dyed. "Take soe much of each of the light collours of silk as be three or four pairs of womans stockins and of such collers as are very currant and good as grein masarein, blew, hair collour, gold and chirie collour ane dozen of each sort" and "orders all maner of collours of worset to be dyed presently as good reids, gold, hair, grein, buff and blew and what other collours shall be thought fit," and further "that white worsted may be prepared for working whyte worsted stockens quhich is to be dyed black."

The first information regarding prices paid for dyeing materials is found in minute 482 of 4th June, 1684 :—

1000 lb. crop mather	£30
300 lb. argall about	£09
200 lb. potasses about	£6
2 hilds of coperas about 40 stivers	£4
30 lb. cusheneill about 26s. sterling the lb.	£39
200 lb. fussick	£00 16s.
200 lb. fanandybuack	

The last item I suppose means Pernambuco wood, the price of which is however not given.

In minute 505 instructions are given to induce a dyer at Kinross to enter the services of the Company :—"That Joseph Young be desired to speak with the dyer at Kinross to try his humor, character, pairts, knowledg, sobriety, how he is imployed if he would remove, and for what."

On 16th July, 1684, we find the name of another dyer who had got into trouble concerning the price and results produced :—"Haveing considered Mr. Cathcart accomptt for dyeing and finds that the charges 4d. per ell for Galloways when it is alledged ther was but 3s. 10d. offered yet finding they are well done they are content to allow him the said four shillings Scotts (4d. sterling) provyding he doe all the rest he is now doeing to content and for the scarlet cloath he soyled in the dyeing apoints to give hime two ells of it to make a tryall for recovery of it and if he doe it to pay him as Lamb was payed, and if he doe it not, to pay hime his dye stuffs provydeing they do not exceed the half of the soume he charged in his accompt quhich is sixty-one$^{\text{lb.}}$ 10s. Scots."

In minute 523 it is stated that the dyer at Kinross had been willing to change his position :—"that Joseph Young write to the dyer at Kinross to come south that we may conclude with him," and in 536 "he writt to John Home the covenants with John Bairns the dyer."

Although large quantities of soap were at the time imported into Scotland, the New Mills works seems to have made some of the soap required, because in minute 556 it is stated "that Perie the sope boyler and Richard Coln the drawer be dealt with to take prentices."

The following delivery of dyestuffs was made on the 29th of April, 1685 :—"ordered Mr. Spurroway and James Marr to deliver to David Maxwell the following dye stuffs, allum, pottasshes, argall, coperas, gall, crop-mather, mull-mather, shoe-make, tarmanick, logwood, wead what of them they can spare . . . and this day considering the loss, trouble, and time is spent in weighing out to David Maxwell the dyeing stuffs in small by the mester and Mr. Marr therfor orders as is above written and that ane abliedgment be given to David Maxwell to take back what he leaves of the said dyeing stuffs at the expireing of his contrack being not within twenty pounds weight, and that notwithstanding of receiveing them he shall have paymentt of the one half of what he dyes and the other to go towards the payment of the dyeing stuffs."

The entry made on 5th September, 1685, is of special interest, because Indigo is definitely mentioned for the first time :—"Orders the writteing for . . . five hundred weight of logwood, ane hogshead of coperas . . . eight hundred weight of shoe-make, to writt to Holland for . . . fivetein pound of aqua fortis . . . and for the price of cusheneill and barbatas and Jameca indigo."

On the 3rd March, 1687, the prices to be paid for dyeing wool were arranged ; David Maxwell had to be paid "for mains two pence per pound ; for mixtures of all collours (in green only excepted) three pence per pound, for woaded blacks three pence per lb. and for ingreen collours twenty pence per pound." These prices must have been in pence sterling, and "ingreen" no doubt has reference to ingrain.

On the same day an order was placed for "makeing ane wadd fatt about fifty gallones."

The minutes of May 12th, 1687, inform us that Robert Debnam, junior, was to sort and also to dye all the wool which his father required, "and for the well dying therof he is to have as followeth viz. :—

For maines 2s. 6d. per score	Trone pound of dyed wooll.
For mixtures 3d. per pound	
For waded black not with indigo but wade 3d. per lb.	
For ingrained collours 18d. per pound	

"These are to be per pound so dyed as to hold in the milne, and if they fade he is to be brought upon rebate."

The dyeing of blacks must have given trouble, on account of the Indigo- or Woad-bottom not having been dyed deep enough, because Maxwell is ordered "anent fyne blacks viz. :—to make the best stall as deep ane blue as is made in England for the best blacks."

Later on it is ordered that Maxwell is to be also paid a better price for these blacks than had been arranged.

On the 21st of June, 1687, the manufacture of "whyte light cloaths" was discontinued, and orders were given for the "dying of whyte searge that lying at Newmilns a scarlet."

It was agreed on the 2nd May, 1688, that Maxwell be paid "fourteen pens per ell for quhich he oblidges himself to dye the best and highest stall of England," or the "fyne blacks," and that he should provide his own materials required for dyeing.

Besides Maxwell, there were however at least two other dyers employed by the firm (minute 1111) :—"Orders that what dye stuffs are to be written for heirafter that they be bowght at Holland for six months time and at London for nyne monthes tyme and what dye stuffs are upon Mr. Maxwaal's accompt be keeped distinctt from the rest of the dye stuffs that are for Mr. Spurways and Debnam's use."

The dyestuffs were evidently supplied by William Blackwood, because on 4th August, 1688, he presented an account for "one hundred pound indigo and fifty pound cousheneill."

In the minutes of 22nd January, 1701, mention is made of weld :—"To desyre David Foullis to wryt to his father to send noe fullers earth and to hasten the strae uald."

The dyers do not seem to have been over anxious to take anybody into their confidence or to accept apprentices, for on April 8th, 1701, the directors deputed two of their number to go to the works and "to treat and speake with the master of the work to prevaill with him to take apprentices to learne his art of dying."

Some information as regards dyeing and dyestuffs used in Kirkcudbright may be gathered from Chalmers[9][*]. "In Galloway they must always have manufactured the wool of their flocks into garments. At the end of the 17th century, they even sold their surplus fabrics of wool to their less industrious neighbours." This is also borne out by Symson who says that in 1684, the country people manufactured much more woollen cloth than they wanted for their own use, and that they sold the surplus at the fairs of Wigton and other parts of the country, to those who could not supply themselves.[†] "The woollen cloth was manufactured from the raw material in its natural hue. The cloth for the men's coats was sometimes made from a mixture of white and black wool, which gave the fabric a very mottled appearance." (Stat. Acc., ix. p. 325.)

---

[*] V. 295.

[†] MS. Account.

Symson further informs us that "in 1684 the people gathered an excrescence which grew on the craigs in the parish of Minigaff, and which they formed into balls that they used for dyeing a purple colour; this they called *corklit*. They gathered another excrescence from the roots of trees, which they called *woodraw*, a kind of forg with a broad leaf; and this they used for dying a kind of orange or *philamort*."

The Acts of Parliament, 1685[4]*, contain a "Ratification of the seal of cause . . . in favour of the litsters of Edinburgh." and in 1686[4], the duty on Madder was raised to £3 Scots per thousand weight.†

In order to encourage the linen manufacture, an Act was passed in the same year,[6]‡ setting forth that "the dead were to be burried in Scotch made linen."

In 1695[6]§ "the Waksters and Litsters of the said Burgh of Dundee protest against the said Ratification in favour of the Nyne Trades within the Burgh of Dundee," because the weavers and the fullers were included but not the dyers. In response to this protest the Act was ratified, and the dyers were incorporated with the fullers under the name of "the waulker trade." Against this decision the town and the trades of Dundee however lodged a protest.

The words "lit, litting, litster," in their various ways of spelling are so frequently quoted in this paper, that an attempt to explain their proper meaning will not be out of place. In the first instance, *lit* or *let* means a dye, a colour, a tinge, a hue, or a stain, but it is difficult to state definitely whether it means a particular kind of dyestuff or whether it was used in a generical sense. The word may have been derived from Litmus, but it is also probable that it is an abbreviation of lichen. It is remarkable that the word lichen has not been found in any of the records which have been examined, although the author feels that it is safe to assume that lichens must have been the principal raw material for the supply of dyestuffs in Scotland in early times. In some of the records we find "bleitsching" in place of bleaching, and if we assume that lichen may have been similarly spelled, the above suggestion does not seem unreasonable.

It is likely that "country lit" refers to this kind of dyestuff, but it is more difficult to explain the meaning of "orchard lit," unless it has been derived from the walnut or some other kind of tree growing in orchards. "New lit" may possibly have meant the lichen before it was prepared for dyeing, whilst "corklit," which was found on rocks, without doubt refers to a kind of lichen similar to Archil.

In Wright[20] we find the following references to lit:—"The *Lichen Tartareus* yields a lit or dye;"—"It's like Pathhead lit, soon on, soon aff;"—"The *Purpura* that lives *in Mari Euxius*, if the fishers strike it on the head it renders out all its blood, and it is an excellent litt;"—"His hands deep dyed in darkest lit;"—"Nouthire to toly ne to taunde transmitte we na vebbis, To vermylion ne violett ne variant littis;"—"Of nae ither litt but the hue of the ewe:"—"The dyster . . . . lost his shop an' a' his claith. His bowies, pots, an' lit."

Only one quotation is given which might be considered as a justification of the statement that lit means "an indigo dye":—

"Dyster Cave, wi' his darkest litt, keeps dippin' awa."

To litt (*litt* or *let*) means to dye or to tinge, *littit* or *littyt* means dyed, and *litting*—dyeing. In the following references the word is used in a general sense:—"Coarse home-made plaiding, litted blue;"[20]—"Wi' a hap o' Sibbie's an' my muckle blue lit froke inunder her head an' shooders;"[20]—"I heve some garne to send with thee to lit";[20]—"Thies clathis sente he hedire to mee For to litte thayme,"[22] and in this paper the word is frequently used in connection with the dyeing of red, violet, blue, scarlet and black.

We have, however, proof in the following references that the word was used distinct from and in addition to the word dyeing, and that in these cases it referred to the dyeing of fast colours only, chiefly Indigo or Woad:—"He'll die all manner of colours but blue, and that is gone to the titting;"[21]—"Weel dy'd and litit through and through;"[22]—"The Woll (shall) . . . bee first dyed and litted and coulered withe the coulour blue;"[22]—"The broo (broth) that they lit the black claith wi'."[20]

From the foregoing we should however not be justified in assuming that litting was applied in general to the dyeing of fast colours, because in this paper references are made to "litstars of fals colours," and further also that "to let is to dye, but not in fast colours."[20]

The word *litster* or *litstar* in place of dyer was no doubt chiefly used in the North, and particularly in Yorkshire and in Scotland. Wright informs us that "The Tinctors were dyers, or in the vernacular of the north 'litsters,'[20] and further that in Yorkshire the word was applied to a female dyer,[20] whilst in some parts of Scotland a dyer was known as "Littie."

In the following, reference is made to a dyer and to the use of argol in dyeing:—"Tak the greia of the Wyne that mene fyndis in the tounnes, that litsters and goldsmythes uses."[21]

As has been shown in the case of the two words litting and dyeing, the words litster and dyer are also frequently found side by side in one and the same record, and whilst the proofs brought forward do not show in every case that the occupation of the litster was distinct from that of the dyer, the author feels justified in suggesting that in many cases such a distinction did actually exist and that the litster occupied a similar position to that held in early times in France by the "teinturiers en bon teint," whilst the dyer might be compared with the "teinturiers en petit teint."

The word lit was also used in a number of compound words, such as "lit- fatt, -fat, -falt," a dye vat; "lit-house, -hous, -hows," a dye house. In Banffshire[20] the "lit-pot" at one time seems to have been an indispensable article in every home:—"Beside the fire stood another pot covered with a slab of stone. It was the lit-pot, *i.e.*, a pot used for the dyeing of wool, *for the most part* of a blue colour, and giving forth when the wool was turned a very strong smell of ammonia."

In the Aberdeen Records we find reference to dye vats in the following:—"Ane gryt *litting leid* price tuenty poundis, ane litil *litting leid* price sax poundis,"[19] and according to a communication received from Mr. Edge, the word "lit-pig" denoted a vessel which was employed in Scotland for the preparation of orchil.

The most important information contained in this paper has been derived from records connected with the burghs on the east coast of Scotland, and particularly with those shipping towns which in the earliest times had an active trade with the Continent and especially with Holland and France. It is probably correct to assume that in these towns materials were employed in dyeing which were unknown in most of the other parts of Scotland, but it would be incorrect to infer from this, that dyeing was necessarily confined to these places. Dyeing, like spinning and weaving, was without doubt practised in the earliest times in every part of the country, and as we have seen from some of the records, the "lit-pot" formed an indispensable article in every home, but as the population increased and as the laws of the burghs became less stringent, dyeing became a distinct occupation in many places outside the burghs.

The author desires to express his thanks to Mr. R. K. Hannay, M.A., and to Mr. C. W. Yule, M.A., of the Historical and Antiquarian Department of H.M. General Register House, Edinburgh, for their kindness in pointing out sources of information and for placing the records in the Register House at his disposal; to Mr. Charles W. Sutton, M.A., Chief Librarian of Manchester, for giving him every facility for consulting the many valuable works in the Manchester Free Reference Library; and last, but not least, to his friend and colleague Mr. T. W. Fox, M.Sc.Tech., for the interest which he has taken in this investigation.

Discussion.

Mr. Hannay observed that as far as his knowledge went, one pound Scots, far from being two shillings sterling, was five pounds sterling. He was surprised to find that in the values read out pounds Scots were given both for wages and for prices paid for materials. Even at the present time in Scotland when a juryman failed to answer to his summons he was fined five pounds Scots (£25 sterling). The lecturer had referred to the privileges of the incorporated trades in Scotland, one of which was to send the deacon of the trades as a representative to the Town Council. That privilege still survived. Year by year in Glasgow, Aberdeen, and other cities the Trades Council met after the November elections, and appointed their deacons for the year, who afterwards went in a body to the Council to be sworn as members of the Town Council. The Dean of Guild, who had charge of all the building operations in the City, was the head of the Trades Council, and was appointed by the brethren of the amalgamating trades. It was a pity that such positions were now sometimes filled by men who had no connection whatever with the trades they represented. For instance, the Deacon of the Dyers and Bonnet Makers in Glasgow for several years had been a lawyer. The industry of bonnet making and bonnet dyeing was a very important one in the west of Scotland until as late as the early 19th century, the burgh of Kilmarnock being recognised as the centre of the industry. Even at the present day he believed Kilmarnock bonnets were made and dyed in the burgh itself. An interesting reference had been made to the circumstance that cloth was made from the wool of white sheep and black sheep. The cloth so woven was known in Scotland as hodden grey (*anglice* homespun). Scottish literature contained many references to characters "clad in hodden grey." Many a Scottish housewife had reason to thank her forbears for weaving so much cloth in the past, much of it having been transmitted in the form of dowries.

Mr. Hübner, replying to Mr. Hannay, said that in the translations of the records referred to one pound Scots was given as 1s. 8d.

Dr. G. J. Fowler said that the primitive methods of the old Scottish dyers were similar to those even now carried on in India. The variety of dyes used by them was very considerable, among them being some which were now in use in India for the finest carpets. Though Indian carpets exhibited a great variety of beautiful designs only three dyes were employed in their manufacture, *i.e.*, lac, indigo, and turmeric, the dyes being considerably "faster" than anything yet produced on the Continent. An old native Indian dyer obtained the most perfect tints with his various dyes by apparent rule-of-thumb, but really as the result of an extraordinary educated knowledge and experience of the effect of different weights of dyes variously applied. While some of the processes they had heard of might appear crude it was well to remember that the personal equation was proportionately great. In modern times everything was made as fool-proof as possible.

Mr. J. H. Reynolds said that some of the methods of the old handicraftsmen, if thoroughly studied, might throw light upon modern methods. He knew not whether the dyestuffs used by the handicraft dyers in India were as fast as modern artificial dyes, but he thought there was substance in the statement that when the fine carpets of Persia or India did fade, if they faded at all, they did so harmoniously and pleasantly, the colour schemes obtained in the fabrics being a delight and a beauty far different to the brilliant effects produced by artificial dyestuffs.

Glossary.

Airt, art.
Allanerlie, only; solely.
Aller barkis, elder bark.
Allum; Alm; Alme; Alom, alum.
Als, as.
Amedoue, starch.
Anhairas (Anherd), to consent.
Anneill, Indigo.
Argell, argol.
Atoure, beyond, as to time; exceeding.
Aucht, ought; should; eight.
Awin, owing.
Awiner, owner?

Ball; Ballis; Bollis, bale.
Baneist, banished.
Barbatas, Barbados.
Barbouris, barber.
Bleicheres, bleachers.
Bleitsche, to bleach.
Bleitcheing, Bleitsching, bleaching.
Blew fatt, blue vat.
Boboning, winding.
Bocht, bought.
Breid, width.
Brissell; Brissele, Brazil wood.
Bron, brown.
Brugis, Bruge.
Byrthing, size; bulk; burden.

Campveir, Veere.
Carsages, Kersey.
Cast, to fade.
Chalmer, chamber.
Chamlet, camlet, a cloth.
Chirie, cherry.
Claith; Clathe, cloth.

Claith serg, serge.
Compeach wood, Logwood.
Conduction, the act of hiring in general.
Copers; Copper, dye vat.
Costis, duty.
Cottoun, cotton.
Cramysse, crimson; also any rich silk.
Crear, a kind of lighter.
Cryit up, proclaim; to call.
Crymosin, crimson.
Culen; Cullan, Cologne.
Cuppruss, coperas.

Danskene, Denmark.
Dayer, dyer.
Daying, dyeing.
Defalt, to adjudge as culpable.
Dekyne, deacon.
Donke, damp; perhaps mouldiness.
Dossin, dozen.
Drawaris, drawers.
Drawin, drawing.

Ell; elne, a measure containing 37 inches.

Faine, fine.
Falt, fault.
Fastick; Fussick, Fustic.
Fatts; Ffats, dye vats.
Feste, feast.
Fewirzer, February.
Flanderis; Flandirs, Flanders.
Flemygis, Flemish.
Flesher; Flesseris, butcher.
Flory, the flurry of the Indigo- or Woad-vat.
Fourt, forth.
Fra, from.
Fre.se, frieze.
Fusteonis, fustian.

Gaid, woad.
Gallis, galls.
Geir, accoutrements.
Gef, gave.
Gif, if; to give.
Gon, gown.
Grane, Cochineal.
Gren, green.
Gudes, provisions; goods.

Haist, the harvest.
Haldand, holding.
Handwarp, Antwerp.
Hoise, hose.

Ilk, each; every.
Ingill, English.

Kark; Cark, a package (of alum).
Kelt, a cloth with a nap.
Kemester, wool comber.
Kettles, dye vats.

Laidnit, loaded.
Laik, gift; pledge; lack.
Last; lastis, a weight or measure.
Lenth, length.
Lettyn; Litting; Lyttin, dyeing.
Lining; Linning; Lyning; Lynnyn, linen.
Lit; Lytt, dyestuff.
Litstair; Litstar; Litstaris; Litster; Littistair; Littisteris; Lytstar, dyer.
Litthouses, dye houses.
Littit; Lyttyt, dyed.
Lyk, like.
Lynt, lint.

Mader; Madir; Madyr; Maldir; Malder; Mather; Matter, Madder.
Mailin' men, farmers.

Mecht, might.
Medoun, meadow ?
Mercat, market.
Messing (Messingerie), the office of messenger-at-arms.
Milne, fulling mill.

Na, nor.
Ne, neither; no; nigh.
Nichtboure, neighbour.
Nocht, not.
Not, note.

Oncostis, expenses.
Or, before.
Oyll, oil.

Pis, piece.
Pok; Pokis; Polks, poke.
Prenteis, apprentice.
Punsioun, puncheon.
Pyp, pipe.
Pris, price.
Pyrattis, pirates.

Quha, who.
Quhilk, which; who.
Quhit, white.

Redyn, clearing; scouring.
Retret (retrett), repealed; reversed.
Rossat; Russatis, russet colour.
Rowan, Rouen.
Rowanis clath, cloth of Rouen.
Rownd holland, rone-skin ?
Rwn, Rouen.
Ryssyllis, a cloth, perhaps named from Overyssell, or from Rousselaere.

Saip; Seip, soap.
Sald; Sawld, sold.
Sarkis, shirting.
Schere, to shear.
Scheryn, shearing.
Schir, Sir.
Schyp, ship.
Scribbling, teasing of wool.
Secund, second.
Seid, seed.
Selleries, salaries.
Sene, since.
Serg, serge.
Sewin, seven.
Sey, sea.
Sheermen, shearers.
Shoe mack; Shoe make, sumac.
Sic, such.
Smal (small), inferior.
Sowters, shoemakers.
Speedful, expedient.
Spill, destroy; spoil.
Stainings, dyestuffs.
Steikis; Steiks; Stek, pieces.
Steming, the cloth now called tamine or taminy.
Stiffinc; Stiffeng, starch; stiffening.
Strae, straw.

Tailyoris; Teylzour, tailor.
Taip, tapistry,
Tany, tawney.
Tarmanich, turmeric.
Tessels, teasels.
Thir, these.
Thalyt, to endure.
Threed, third.
Thrummes, drums (warp beams).
Tinsaill, loss.
Tone; Towis; Town; Twnnis, a ton.
Toun, town.
Treis, barrels.
Trew, to trust.

Trie, a stick.
Tua, two.
Tyne, to lose.

Uald, weld.
Ursell, Orchil.
Utheris, others.

Vad; Vaid; Veyade, woad.
Vebstaris, weavers.

Wabstaris; Wobstaris; Wobster, weaver.
Wad; Wade; Wadd; Waid; Wead; Wod, woad.
Waded, woaded.
Wak, moist; watery
Wakers; Waksters; Walkaris; Walkers; Waulkers; Wolcaris, fullers.
Walkmilne; Wakmilne, fulling mill.
Wald; wauld, weld or perhaps woad.
Washe, stale urine.
Wast, waste.
Watt, wet.
Watter, water.
Weand, weighing.
Weazel, Wesel.
Wecht; Weght, weight.
Welwat, velvet.
Wester, western.
Wheills, wheels.
Whilk, which.
Whyt, white.
Wirk, work.
Wob, web.
Wobis, webs.
Wont to be, a custom or practice that prevailed in former times.
Worset, worsted.

Zarne, yarn.

Meeting held at Armstrong College, on Wednesday, March 18th, 1914.

MR. E. F. HOOPER IN THE CHAIR.

THE USE OF COAL TAR CREOSOTE AND NAPHTHALENE FOR PRESERVING WOODEN FENCES.

BY S. H. COLLINS, M.SC., F.I.C., AND A. A. HALL, PH.D., M.SC.

Although there is no lack of literature on the subject of creosote yet there is so much difference of opinion about what is necessary and what unnecessary that it is difficult to obtain much useful information on the subject. A very fine abstract of recent work may be found in Allen's Commercial Organic Analysis, Vol. III., but the contradiction on the subject may be well illustrated from that work. On page 368 occurs the statement "naphthalene is volatile at all temperatures and will disappear entirely from the wood in course of time," but on page 371 may be read "The naphthalene of coal-tar creosote volatilises only from the superficial strata of the timber." Further, although much work has been carried out on the subject of the determination of tar-acids and tar-bases and much importance has been attached to those bodies, yet Charitschkoff* considers that although the phenols and nitrogenous compounds by themselves exhibit considerable antiseptic properties, their presence in creosote only slightly increases the antiseptic power of the latter.

Probably this contradiction is due to excessive generalisation, and the authors propose to restrict themselves to a study of the processes of creosoting so far as they apply to small timber such as is used in estate fences, where the posts are subjected to different conditions of air and soil.

PART I.

The usual method for the assay of coal tar creosote consists in taking the specific gravity at 60° C. and then taking 100 grms. of the creosote in a tared 250 c.c. distillation flask, and distilling with the bulb of the thermometer opposite the mouth of the outlet tube. The water is estimated by collecting that fraction boiling under 180° C. in a graduated cylinder and mixing with an equal bulk of benzene and then measuring the water.

The distillation is then continued up to 316° C., the distillation taking about 15 minutes, the total volume of distillate is noted and the residue in the flask after cooling is weighed. During the distillation note is taken of the amounts coming over at different temperatures, particularly at the temperatures of 205° C., 215° C., 220° C., 245° C., 271° C., 300° C., and 316° C.

The tar acids are determined in the whole distillate by extraction with three lots of warmed 12 per cent. caustic soda of 25 c.c., 15 c.c., and 10 c.c. respectively. The caustic extract is washed three times with ether, the ether collected and washed with 5 c.c. of the soda solution, which is then mixed with the main quantity of the soda extract; this is placed in a 200 c.c. burette and heated on the water-bath until all the ether is expelled, cooled and 50 per cent. sulphuric acid added until the whole is acid, the burette is then allowed to cool and the volume of the tar acids is read off. If desired the tar bases are estimated in a similar manner by extraction with sulphuric acid.

The naphthalene is determined either by direct filtration, or by precipitation with picric acid. This latter method gives the total hydrocarbons (naphthalene and others) capable of yielding insoluble picrates. The precipitation is carried out on a portion of the distillate from the crude creosote by diluting with glacial acetic acid and then adding a large excess of a saturated solution of picric acid warmed to 80° C. After cooling the precipitate is filtered off, washed with picric acid solution, and dissolved in $N/10$ NaOH. The excess of caustic soda is then estimated by titration with $N/10$ H_2SO_4. If most of the insoluble picrate were due to naphthalene each cubic centimeter of $N/10$ alkali used would be equivalent to 0·0128 grm. naphthalene. The authors attempted to estimate the tar acids directly by taking 5 c.c. of the original creosote, diluting with 50 c.c. ether and extracting successively with 10, 5, and 4 c.c. of 12 per cent. NaOH. This was washed into a Gerber tube, the ether boiled off and 3 c.c. conc. sulphuric acid added, the tube was then spun and the volume of the tar acids read off.

This method was found to give much lower results than the previous one. This is due apparently to the large excess of ether used, as was proved by an experiment in which low boiling petrol was used instead of ether. The petrol method gave a higher result, but not such a high result as the direct extraction of the distilled creosote.

In order to test the value of the picric acid method for the estimation of naphthalene, the naphthalene was estimated in a sample of creosote by this method and also by very careful distillation of the creosote with a Young's "rod and disc" still head of twenty discs. The latter method gave results on an average 20 per cent. lower than the picric acid method. As in this second method the naphthalene was isolated and its melting and boiling points taken, and as the distillation was carried out in such a way that no naphthalene could be lost, it was decided that the second method gave results more approaching the truth than the first method. There was a possibility that some of the naphthalene had been decomposed by over-heating, so the experiment was made of fractionating some creosote, collecting the fractions, mixing them together and re-fractionating. This was done four times, and it was found that the fourth distillation gave the same quantities of distillate at the different fractions as the first, showing that neither the naphthalene nor the other constituents of the creosote were decomposed.

---

* See this Journal, 1912, 456.

Experiments were also carried out to see if it were possible to separate out some of the constituents of the creosote by distillation in steam. It was found that the creosote was only very slightly volatile in steam, and that the distillate was almost as great a mixture as the original creosote itself.

These experiments show that the best method for the assay of creosote is to carefully distil it, using a long still head of the "rod and disc" type up to a temperature of 271° C., and then a shorter one until the temperature reaches 316° C. The naphthalene comes over between the temperatures of 205° C. and 220° C. These fractions solidify in the receiving vessels, and on cooling can be weighed and the melting point taken. The liquid fractions coming over above and below these temperatures yield some more naphthalene on refractionation. But this error never amounted to more than one per cent.

Part II.

Experiments have been made to study the quantity and quality of the preservative left in the wood after treatment and after many years use. For this purpose large wooden posts that had been treated with preservative were examined in the following manner. Ordinary commercial methylated ether was purified by fractionation through a Young's "rod and disc" still head of about one meter in height. To avoid risk of fire, the heat was supplied by a 32 candle carbon filament lamp surrounded with asbestos. Only the fraction, 28° to 36° C. was used, the remainder serving for cleaning. The ether so purified was used for extracting the wood in a large extractor on the principle of the well-known "Soxhlet." The wood selected for examination was shaved with an ordinary carpenter's plane set to cut .coarse shavings. About 150 grms. of such shavings were placed in the extractor which had a capacity of about one litre and was connected up with a flask of about 1½ litres capacity, containing about 1¼ litres of ether. A large tin condenser served to return the ether to the extractor. The colour of the extract readily indicated when the extraction was finished and as a rule a fresh charge of wood shavings was put in as soon as the former charge had been completely extracted. By these means an extract from about 150 to 600 grms. of wood was obtained. The ether was then distilled out again by the same method of heating and fractionation as was used for preparing the rectified ether of low boiling point and the extract was then weighed and bottled for further examination. By no means had the whole of the ether been removed at this stage, but a further treatment was needed and was supplied along with the fractional distillation of the extract. The ether that had been recovered was tested for naphthalene by the picric acid test with negative result.

The fractional distillation of the crude ether extract was conducted with a "rod and disc" still head of about three decimetres in height, with a condenser only in use during the first part of the fractionation. Everything distilling under 100° C. was considered as ether, all above that temperature was considered as preservative. As may be seen from the accompanying figures the separation was quite sharp, indeed in most cases nothing measurable came over between 70° C. and 170° C. The original weight of crude ether extract had then to be corrected for the amount of ether in that extract so as to give the figures called preservative in the Table I.

The fractionation was continued up to 316° C., for which purpose a nitrogen filled thermometer was used. The results were plotted as curves, but for the purpose of this paper only the most salient points on those curves are noted in the tables.

The first column in Table I. shows the results obtained from an ash post that had been treated with creosote and had been in the ground for one year. The amount of preservative in the wood when air dry was 10·72 per cent. and of this amount none distilled at low temperatures, nor could any naphthalene be found. Somewhat similar results were obtained from a beech post shown in the second column.

The third, fourth and fifth columns show the results obtained from a post of Scots pine which had been treated with creosote fourteen years before and had been used in a light sandy soil. This post was cut into three lengths and each portion shaved as before. It is noteworthy that the middle portion, which stood just about the ground level, kept its creosote much better than either of the other two portions and further that the creosote so kept retained a much higher proportion of light boiling fractions. The creosote appeared to have leaked out of the point to some extent and to have evaporated or been washed out of the top. Unfortunately we have not been able to obtain samples of the creosote actually used, but all samples of creosote used at present and all such old samples as we can obtain show the presence of naphthalene from about 5 to 15 per cent. It will be noted that in all these cases where creosote was used no naphthalene was found.

The remaining six columns in Table I. show results obtained from the treatment of wood with naphthalene. The naphthalene was melted in open tanks and the posts submerged, covered and allowed to soak for some hours. The post of Scots pine recorded in column 6 had been preserved fourteen years before, but had never been used. The very large amount of preservative still left in the wood after all these years shows that naphthalene does not evaporate so very fast, so long as it is imprisoned in the wood. Observation of the posts showed that the naphthalene had evaporated from the surface, but that at a little depth the naphthalene was still there. In columns 7 and 8 are shown the results from a post that had been twelve years in mossy ground. Similarly columns 9, 10 and 11 refer to a post that had been 13 years in light gravel. In all cases the proportion of oil other than naphthalene is far too high to belong to any naphthalene crystals likely to have been used. That such concentration of oils should have originated in simple evaporation seems improbable. Is it possible that naphthalene could oxidise or polymerise in many years time in the pores of the wood? Further, one must consider the disappearance of the naphthalene from the creosoted wood. Is this loss due to evaporation? Might it not be due also to some other cause as suggested above. Further experiment is necessary to settle such a point. Sycamore wood contains nothing soluble in ether, although the Scots pine might have a small amount.

The alteration in composition of the creosote as a result of treatment of timber is shown in Table II. The more volatile portions of the creosote show a tendency to be lost during treatment, especially during open tank treatment.

Conclusion.

The only satisfactory method of determining naphthalene in creosote is by fractional distillation with a "rod and disc" still head.

Crude naphthalene is a splendid preservative for timber, but so much is absorbed that the expense is great. Evaporation of naphthalene seems limited to the surface of the post.

Creosote disappears from the exposed parts of a post and also from the point, but the middle part where decay is most likely to occur keeps its creosote fairly well.

The more volatile portions of creosote are easily lost.

Part of the expense of this investigation has been defrayed from a special grant by the Board of Agriculture.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows; Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris 3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

Multiple effect evaporation; An experimentol study in ——. N. Deerr. Hawaiian Sugar Planters' Assoc., Bull. No. 42, 1914, 1—47.

The calculated effect of self-evaporation in a multiple-effect evaporator is never realised, owing to the superheating of vapours and loss of steam with the incondensable gases. The rate of evaporation is influenced not only by the gross temperature difference, but also by the absolute temperature prevailing, increasing as this increases. Increase of the gross temperature difference by decreasing the temperature at the cold end down to that corresponding to a vacuum of 27 inches, gave a material increase in the rate of evaporation, but not so great as that obtained by increasing the temperature (or pressure) of the direct steam at the hot end. The heat-economy of quadruple effect evaporators in practice was found to be between 0·8 and 0·9. A vertical submerged tube apparatus with 5 lb. gauge pressure in the first cell (227° F., 108·3° C.) and not less than 26·5 inch vacuum in the last cell (127° F., 52·8° C.) should evaporate not less than 9 lb. of water per sq. ft. per hour, with juice entering at 212° F. (100° C.), and should evaporate 4·2 lb. of water per lb. of steam. If these conditions are not realised, foul heating surfaces, too slow removal of condensed waters or incondensable gases, may be suspected. A horizontal tube film evaporator had a much greater rate of evaporation than vertical submerged tube evaporators.—L. J. de W.

Patents.

Drying, revivifying and decarbonising bone-black; Apparatus for —— *or for treating other granular or finely-divided materials.* J. Wetter, London. From M. Weinrich, Yonkers, N.Y., U.S.A. Eng. Pat. 6347, Mar. 14, 1913.

The treatment is effected, as usual, in a revolving cylinder provided inside with projecting radial or slightly inclined blades, but to increase the working capacity of the cylinder the blades are made of greater width; and near their free ends they are provided with longitudinal slots through which the material falls in fine streams; the passage of the material through the slots may be facilitated by a tapping device. At the discharge end of the cylinder is a retaining rim having outlets which can be opened or closed as desired.—A. S.

Drying and heating sand, grit or like materials; Method and means for ——. T. and F. Coleman, Derby. Eng. Pat. 20,161, Sept. 6, 1913.

A fixed horizontal circular plate is arranged above a similar rotating plate. Annular plates project upwards with an outward inclination from the lower plate and other annular plates, vertical or inclined inwards, depend from the under side of the upper plate into the spaces between the upstanding plates. The material is fed from a hopper on to a distributing plate just above the centre of the rotating plate and is driven outwards by centrifugal force, a current of heated air being at the same time passed through the spaces between the plates.—W. H. C.

Smoke; Means for washing ——. J. D. Jackson, Kensington, Victoria, Australia. Eng. Pat. 19,762, Sept. 1, 1913.

The process described in Eng. Pat. 4636 of 1913 (this J., 1914, 341) is improved by providing means for heating the washing liquid and for adjusting the spraying devices both vertically and horizontally.—W. H. C.

Dust from air or vapour; Process and apparatus for extracting ——. J. Herbing, Halle a/Saale, Germany. Eng. Pat. 20,700, Sept. 13, 1913. Under Int. Conv., April 14, 1913.

The dust-laden air or vapour is passed in succession through a series of hemp filters, of increasing fineness, arranged at an angle of at least 60° within a casing. —W. H. C.

Gas; Apparatus for subjecting —— *to the action of liquids.* F. H. Wagner, Assignor to The Bartlett Hayward Co., Baltimore, Md. U.S. Pat. 1,091,464, March 24, 1914.

In each of a series of superposed chambers is a rotary device fitted with vanes designed to carry up and spray the liquid in the chamber. A partition extends under and partly round each rotating device, so that the gas may pass up at one side thereof, be acted upon by the sprayed liquid and pass out at the opposite side, the washing liquid being circulated in the contrary direction.—J. L. F.

Gases; Purification of —— [*from suspended particles*] *by formation of mist by supersaturation.* E. Möller. Ger. Pat. 270,757, Feb. 7, 1912.

The gas is first subjected to electrical discharges, or washed or otherwise treated to remove impurities capable of interfering with the subsequent supersaturation. A mist is then produced by supersaturation of one of the constituents or of an added gas, and the particles forming the mist are rapidly separated by the action of electrical discharges, centrifuging, or the like. The supersaturation-mist may be produced by the interaction of two gases, the saturation temperatures of which are higher than that of the reaction product, or by alteration of the thermodynamic condition of one of the constituents. The gases may be circulated alternately through a chamber in which the mist is produced and a device in which the particles are separated. For example, for purifying burner gases for use in the contact process for the manufacture of sulphuric acid, sulphuric acid mist is produced by periodically adding steam and sulphur trioxide to the gases at a suitable temperature; whilst for obtaining germ-free air, water-mist is repeatedly produced and separated in chambers the walls of which exert an antiseptic action.—A. S.

Purifying gases; Disintegrator-like device for ——. J. Hartmann. Ger Pat. 271,201, April 1, 1913.

The gas passes through annular chambers formed by concentric perforated drums and is brought into intimate contact with water spray by centrifugal devices rotating in the chambers. The centrifugal device in each chamber rotates in the opposite direction to that in the adjacent one.—A. S.

Steam and air dryers, oil separators and the like. J. E. L. Ogden, Liscard, Cheshire. Eng. Pat. 21,731. Sept. 26, 1913.

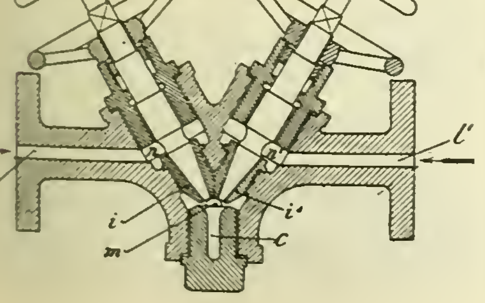
The steam or air is passed through a number of parallel narrow curved pipes, having slots at frequent intervals on the outer side of the curve. The metal of the pipe is pressed inwards at the slots so as to form sharp edges, which project into the tubes and arrest the liquid particles. —W. H. C.

Mixing or agitating device or apparatus. B. Goldman and Galvanische Metall-Papier Fabrik A.-G., Berlin. Eng. Pat. 24,587, Oct. 29, 1913.

The mixing vessel is divided into a number of unequal compartments by radial, vertical partitions, which are recessed at their outer ends near the wall of the vessel. The mixing device or stirrer may be below or above the partitions, or it may be situated at about the middle of the vessel, with partitions both above and below.—W. H. C.

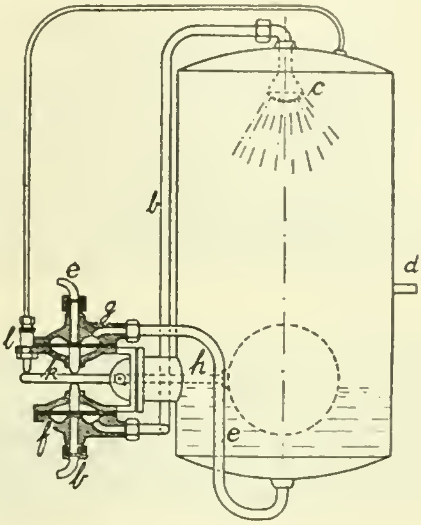
Mixing liquids and rendering them homogeneous; Process for ——. F. M. Berberich. Ger. Pat. 271,432, July 26, 1912.

The apparatus is shown in the figure. The liquids entering respectively through l and l^1, pass into the annular passages, n and n^1, and thence through the narrow channels between the conical plugs, i and i', and their seatings. The issuing jets of liquid are directed into the passage, c, from which the mixture flows into the discharge channel, m.—A. S.



Mixing liquid with gas; Automatic regulation of the supply of liquid to, and discharge of liquid and removal of gas from, pressure-vessels for ——. W. Noll. Ger. Pat. 271,641, May 9, 1913.

The liquid enters the pressure-vessel through the tube, b, and rose, c, and the gas through the tube, d, whilst the liquid saturated with gas is discharged through the pipe, e. The ball-float and lever, h, k, act on the diaphragm-valves, f, g, and the blow-off valve, l, so that as the float rises, the liquid supply and blow-off valves are closed, and the liquid-discharge valve opened, whilst as the float sinks, the valves are operated in the reverse manner. —A. S.



Coal, ores, etc.; Method of and means for separating different kinds of minerals such as ——. J. W. Blackhurst, Chesterfield, and I. C. Blackhurst, Sheffield. Eng. Pat. 26,418, Nov. 18, 1913.

The material is dropped from a suitable height into a vessel containing a running stream of water, which carries the substances of lower specific gravity further from the vertical line of descent. Scraper-conveyors at the bottom of the vessel collect separately the lighter and heavier substances. These conveyors may comprise grids running in troughs so as to separate the smaller from the larger pieces of the substances having similar specific gravity. Jets of air or steam may be blown through the falling material in order to remove dust.—A. T. L.

Furnaces; Process of lining ——. B. E. Eldred, New York. U.S. Pat. 1,091,567, March 31, 1914.

For making and repairing furnace linings a mixture of fine refractory material, such as dolomitic lime, with a carbonaceous substance, *e.g.* tar, is projected against the wall of the furnace by a jet of gases, *e.g.* combustion gases, capable of protecting the material from combustion. —A. S.

Retort or still. J. H. Castona, Laine, Miss., Assignor to Castona Improved Process Co., Gulfport, Miss. U.S. Pat. 1,092,018, March 31, 1914.

A cylindrical retort is closed below by a removable bottom above which is a fixed false bottom, the intervening space forming a water-jacket, which is provided with a valved overflow pipe. The counterbalanced lid of the retort fits in an annular groove in, and is pivoted to, an abutment ring, fixed to the top of the retort. Inside the retort is a removable cage, the perforated bottom of which is spaced away from the false bottom of the retort to form a collecting chamber. A steam-supply pipe extends upwards within the cage and through the lid of the retort, to which it is detachably connected. A drain pipe from the collecting chamber passes out through the water-jacket and is jacketed by the water-supply pipe. A second water-supply pipe is connected below with the water-jacket and above with the upper part of the retort.—A. S.

Extracting apparatus. J. H. Castona, Gulfport, Miss. U.S. Pat. 1,092,019, March 31, 1914.

A car travels upon rails laid in a horizontal casing, the open end of which can be closed by a door. A perforated pipe, mounted on uprights, extends along the car and carries a perforated cage, open at the top, which can be tilted to discharge spent material. On the bottom of the casing, between the rails, is a heating coil. A heating or extracting fluid is supplied to the perforated pipe through a pipe passing through the door of the casing, and in the upper part of the casing, above the open top of the cage, are a solvent-supply coil and a perforated solvent-discharge coil.—A. S.

Metallic vessels for alcoholic fermentation and for the transport and storage of liquids; Manufacture of——. H. Held. Fr. Pat. 464,337, Oct. 31, 1913.

The vessel, containing sand or similar material, is rotated, rolled or oscillated about its longitudinal axis, then washed with weak acids or other cleansing agents such as milk of lime, and the interior surface coated successively with tin or zinc, with copper, and with silver or gold.
—J. H. L.

Crystallisation; Apparatus for continuous——. F. A. Bühler. Fr. Pat. 464,548, Aug. 13, 1913. Under Int. Conv., Aug. 16, 1912, and Feb. 8, 1913.

See Ger. Pat. 268,409 of 1912; this J., 1914, 188. The agitator blades may be prolonged to meet the central shaft, so that as they rotate, the material slides over their entire length. The ends of the blades may be provided with tooth-like projections.—T. F. B.

Filter-presses; Chamber-plate for——. J. Trommer. Ger. Pat. 271,527, Sept. 25, 1913.

A sheet of wire gauze stretched in an iron frame is provided on both sides with a layer of filtering material ("*Steinmasse*"), recessed so as to form filter-chambers when a number of the plates are assembled in a press.
—A. S.

Catalytic reactions; Process for carrying out——. E. W. Andersen, Glostrup, Denmark. Eng. Pat. 7839, April 3, 1913. Under Int. Conv., May 14, 1912.

See Fr. Pat. 457,569 of 1913; this J., 1913, 999.—T. F. B.

Drying chambers. J. J. F. Balés, Talence, France. Eng. Pat. 8509, April 10, 1913.

See Fr. Pat. 455,223 of 1913; this J., 1913, 859.—T. F. B.

Drying air; Process and apparatus for——. F. A. Daubiné, Auboué, France. U.S. Pat. 1,092,434, April 7, 1914.

See Fr. Pat. 411,270 of 1910; this J., 1910, 959.—T. F. B.

Furnaces; Regenerative gas——. F. K. Siemens, London. Eng. Pat. 17,956, Aug. 6, 1913. Addition to Eng. Pat. 10,824, May 7, 1912.

See Fr. Pat. 461,938 of 1913; this J., 1914, 342.—T. F. B.

Evaporator. F. Schulz, Weetzen, Germany. U.S. Pat. 1,091,897, March 31, 1914.

See Ger. Pat. 254,486 of 1911; this J., 1913, 184.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coke-ovens; The heating of——by foreign gas. R. Biermann. Stahl u. Eisen, 1914, **34**, 620—624.

In view of the high thermal value of coke-oven gas, it is more economical to use poorer gases (*e.g.*, blast-furnace gas and producer gas from coke breeze) for heating the ovens. Comparative data obtained when using blast-furnace gas and coke-oven gas with similar ovens are given. The chief difference in working is that the blast-furnace gas as well as the air is preheated in regenerators. The gas is freed from dust down to 0·03 grm. per cub. m. Blast-furnace gas has the advantages of being free from tar and naphthalene, and of not sooting the burners.
—T. St.

Asphaltums; Differentiation of natural and oil——. E. C. Pailler. J. Ind. Eng. Chem., 1914, **6**, 286—289.

For distinguishing natural asphaltums (Trinidad and Bermudez) from those prepared from asphaltic petroleum, the author makes use of the fact, observed by Marcusson (this J., 1911, 480), that the first portions of distillate from the former contain organic acids or acid salts and saponifiable oils. 30 grms. of the asphaltum are distilled in a small retort at the rate of about 1 drop in 2 seconds, and two 5 c.c. fractions are collected in tared weighing bottles. Each fraction is dissolved in 10 c.c. of ether, washed with water, treated with 75 c.c. of alcohol and the acid value (calculated to mgrms. KOH per 1 grm. of distillate) determined by titration with $N/10$ sodium hydroxide, using 5 c.c. of a 1 per cent. alcoholic solution of "alkaline blue" as indicator. To determine the content of saponifiable matter, a solution of 5 grms. of the ash-free asphaltum in 30 c.c. of benzene is boiled with 50 c.c. of $N/1$ alcoholic potash under a reflux condenser, cooled, treated with 250 c.c. of 95 per cent. alcohol, and titrated with $N/1$ sulphuric acid, using "alkaline blue" as indicator: the titration is continued until the colour change is not affected by heating the solution on the water-bath. A blank test must be made. Some results obtained are shown in the following table:—

Kind of asphaltum.	Acid values.		Saponif. value.
	1st Dist.	2nd Dist.	
Trinidad	15·7—16·2	7·9—8·4	40·0
Bermudez	9·6—9·8	3·2—3·6	28·0
California	0·11—0·19	0·04—0·07	12·0
Maltha flux	0·12—0·16	0·19—0·25	8·0
Bermudez maltha	9·8	2·3	—
Mexican	0·22—0·24	0·05—0·09	10·5
Bermudez + California (1 : 1)	4·9	1·2	20·5
Bermudez + Mexican (1 : 1)	5·4	2·0	19·7
Trinidad + California (1 : 1)	—	—	26·9
Trinidad + Mexican (1 : 1)	—	—	24·9

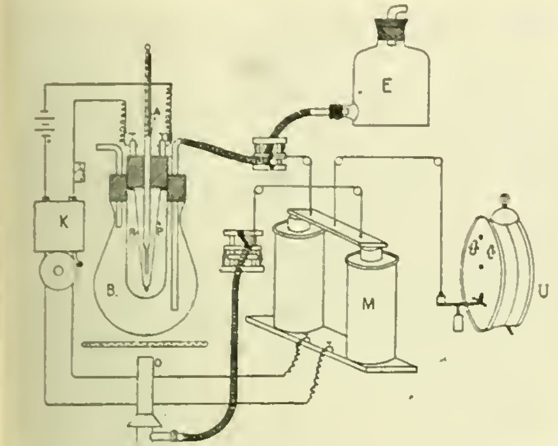
Bermudez + Mexican + maltha	5·15	1·22	—

—A. S.

Asphaltum; Determination of the melting point of——. L. Schanin. Z. angew. Chem. 1914, **27**, 215—216.

The apparatus used is shown in the figure. The asphaltu or pitch is introduced while molten into a capillary porti at the lower open end of a tube, A, and allowed to solidif

A layer of mercury about 5 mm. thick is introduced above the solid pitch. The tube, A, is then supported above the metal plates, P, which are separated by about 1 mm. at the lower end and are in circuit with a bell, K, a battery, and an electro-magnet, M. The bulb of a maximum thermometer is supported near the capillary tube, which together with the plates, P, is enclosed in a test-tube supported in a flask, B. The flask is about one-third full of water and is heated gradually. When the pitch melts, the mercury runs through the capillary tube and completes the circuit between the plates, P, whereupon the bell, K, rings, and the electromagnet is energised so as to shut off the gas supply to the burner, D, and admit cold water from a vessel, E, to the flask, B. The apparatus is thus cooled and the maximum thermometer indicates the melting point. The electro-magnet may also be arranged to stop the clock, U.—A. T. L.



Gas standards. Decision of House of Lords Committee. Times, May 1, 1914. [T.R.]

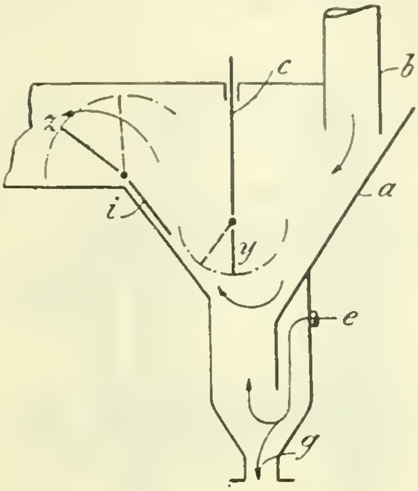
THE Select Committee of the House of Lords has considered the Bill promoted by the Gas Light and Coke Company to abolish the test of the illuminating power of gas supplied and to insist only upon compliance with a standard of calorific value, and has decided to abolish the illuminating test for penalties, but to maintain that test for the purpose of information. They have also decided that the calorific value of the gas supplied by the company shall be one of 540 British thermal units gross, with an allowance of 7½ per cent. to cover lapses or errors in production. Penalties will not be imposed unless the gas falls below the minimum standard of 495·5 British thermal units. Seventeen other gas companies who are promoting Bills in the present Session have agreed to be bound by the decision of Parliament in regard to the Gas Light and Coke Company's Bill.

Oil resources of the Empire. Perkin. *See* XII.

PATENTS.

Washing coal and other minerals; Apparatus for ——. P. Habets, Montegnee, and A. France, Liege, Belgium. Eng. Pat. 17,011, July 24, 1913.

THE coal or other material is delivered by a stream of water through the pipe, *b*, into a hopper, *a*, and is met, at the restricted passage formed by the partition, c, by an upward flowing stream which enters at *e*. The heavier particles are discharged with part of the water at *g*. The partition, c, is adjustable, the areas of the passages or the two streams being varied simultaneously, in order hat the velocity of the downward stream may be reduced o a minimum consistent with the maintenance of a sufficient velocity in the upward stream to carry away the lighter particles. A finer adjustment is effected by means of a hinged flap, *y*, at the bottom of the partition, c.



An inclined shutter, *i*, with hinged flap, *z*, in the delivery side of the hopper removes any suspended particles which accumulate there. In a modification, several ascending streams enter through passages in the bottom of the hopper, a solid inclined flap is arranged at the inlet side of the partition and small flaps are arranged, behind the solid flap and separated from it, above each of the vertical passages. (See also Eng. Pats. 22,655 of 1912 and 5519 of 1913.)—A. T. L.

Briquetting coal with waste sulphite-cellulose lyes and an inorganic substance. B. Grätz. Ger. Pat. 271,479, Dec. 17, 1912.

THE inorganic substance used is aluminium hydroxide, preferably in the gelatinous condition.—A. S.

Coke-oven; Regenerative —— with accessible conduits in the foundation. C. Still. Ger. Pat. 271,515, June 24. 1913.

THE arches supporting the ovens are closed against the accessible conduits below by a horizontal course of bricks. Air is circulated through the passages between the latter and the arches and then passes to the regenerators. Excessive rise of temperature in the conduits below the horizontal course of bricks is thus prevented and these remain accessible while coking is proceeding.—A. S.

Coal-gas; Apparatus for the manufacture of ——. R. C. Congdon, Atlanta, Ga. U.S. Pat. 1,090,813, March 17, 1914.

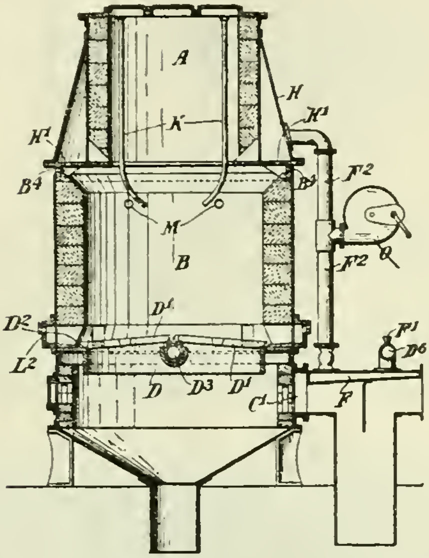
EACH group of retorts is connected with a common stand-pipe sealed in liquid above and below and through which the gas is withdrawn. Liquid is caused to flow down through the stand-pipe without entering the retorts.
—W. H. C.

Generating gas; Apparatus for ——. D. D. Barnum, Worcester, Mass., and H. A. Carpenter, Sewickley, Pa., Assignors to Riter-Conley Manufacturing Co., Pittsburgh, Pa. U.S. Pat. 1,091,111, March 24, 1914.

BENCHES of gas retorts consisting of two vertical rows of retorts, the long axes of those in each row being in the same vertical plane, are connected, the one row of one bench and the adjacent row of the next bench, to a vertical stand pipe, which is placed between them. The stand-pipes are connected to the "foul main."—J. L. F.

Gas-producers. W. R. Degenhardt. Fr. Pat. 464,265, Oct. 30, 1913.

In a down-draught suction gas producer for continuous working, the fuel-chamber, A, above the producer-chamber, B, is surrounded by an annular chamber, H, for the distribution of air and steam through a ring of holes, H¹. The grate consists of separate perforated bars, D^1, which fit against one another, without intervening spaces, and are supported by a ring, D, and a hollow bar, D^3, which passes diametrically across the producer. The outer ends of the grate bars can be raised and lowered by a tool inserted through holes, L^2. Air is drawn through the hollow bar, D^3, into a vaporising chamber, F, heated by the gas as it leaves the space beneath the grate. Water is admitted continuously to the vaporiser at F^1, and the mixed steam and air pass through the pipe, F^2, to the distributing chamber, H. This chamber may be replaced by an annular pipe outside the producer casing, connected with a similar perforated pipe within the casing, or by an annular chamber within the producer casing surrounding the upper part of the producer chamber. A further supply of air is admitted through pipes, K, extending vertically downwards through the fuel-chamber. Poking holes, B^4, are provided at the top of the producer chamber.—A. T. L.



Gas for lighting and heating ; Production of —— by the action of steam above 800° C. on a mixture of fuel and lime. L. Vignon. Fr. Pat. 465,129, Jan. 29, 1913.

The process described in the Third Addition, dated Feb. 6, 1911 to Fr. Pat. 416,699, Aug. 12, 1909 (this J., 1912, 481), is effected at a higher temperature, viz., above 800° C., and if desired up to 1100° C. or 1200° C. The reaction is: $2CaO+3C+4H_2O=2CaO+2CO_2+2H_2+CH_4$. The higher temperature increases the velocity of the reaction, and prevents the formation of calcium carbonate. Part of the carbon dioxide is reduced to carbon monoxide, and small quantities of hydrocarbons other than methane, such as ethylene, are formed. The carbon dioxide may be removed from the gas by washing, and the carbon monoxide may be converted into methane as described in Fr. Pat. 416,699 (this J., 1910, 1366).—A. T. L.

Oil-gas ; Process for obtaining —— of uniform quality during the whole of the gas-making period in producers. J. Pintsch A.-G. Ger. Pat. 271,270, May 11, 1913.

The oil-supply pipe is fitted with a throttle-valve which is gradually and continuously closed during the gas-making period, so that as the temperature falls, the supply of oil is diminished. In this way 80 per cent. or more of the calorific value of the oil is recovered in the gas instead of 60 per cent. as usual.—A. S.

Ammonia and combustible gases ; Conversion of animal substances [waste leather] into ——. A. T. Smith, London. Eng. Pat. 5348, Mar. 3, 1913.

Waste leather is mixed with coal, slack, or coke, and limestone or lime, in any of the usual types of gas producers, operated with a mixture of air and steam. About 70 per cent. of the nitrogen contained in the leather is evolved as ammonia, which is absorbed in the usual way, the unabsorbed, combustible gases being utilised in any desired manner.—O. R.

Ammonia from gases ; Removal of ——. J. Marr, Sheffield. Eng. Pat. 6291, Mar. 13, 1913.

Gases from the dry distillation of coal or the like, are cooled to condense tar and gas liquor, and the latter is treated with steam and an alkali. The steam and ammonia evolved are mixed with the residual gases from the first condensation, passed through a water separator, to remove the water fog together with any tar which may still be present, and finally to a saturator.—O. R.

Condensers used in gas works. G. F. H. Beard, J. W. Scott and R. and J. Dempster, Ltd., Manchester. Eng. Pat. 26,970, Nov. 24, 1913.

Inside a vertical casing having an inlet and outlet for the gas, are vertical water tubes fixed at the lower end to a stationary, and at the upper end to a movable tube-plate, to permit of expansion. The upper tube-plate has a flange extending downwards from its periphery and sealed in a water trough. The water passes up through the tubes and flows over the upper tube-plate into the water-seal which is provided with an overflow. The flange may extend downwards nearly to the bottom of the condenser, thus providing a large additional cooling surface.—A. T. L.

Separating dust, etc., and sulphur compounds from producer-gas, water-gas, and the like ; Purifier for ——. Berlin-Anhaltische Maschinenbau A.-G. Ger. Pat. 271,122, Dec. 12, 1912.

Within and spaced away from the wall of the purifier is a retort packed with turnings of iron or other metal capable of combining with sulphur compounds. Except at the two ends the wall of the retort is porous. The gas enters the purifier, and passes through the porous wall of the retort, which retains dust, etc. A blast of air may be passed into the purifier to bring it to, and maintain it at, the requisite temperature for the retention of the sulphur compounds by the iron turnings.—A. S.

Blast-furnace gases ; Purification of ——. W. Schwarz. Ger Pat. 271,303, April 24, 1912.

Lime-water or other suitable solution is added to the water used in the known forms of purifiers (centrifugal washers, disintegrator devices, etc.), so that in addition to dust and the like, carbon dioxide is also removed from the gas.—A. S.

Mineral oil into volatile spirit ; Apparatus for converting ——. The New Oil Refining Process, Ltd. and J. L. Rossini, London. Eng. Pat. 13,726, June 13, 1913.

In carrying out the process described in Eng. Pats. 13,675 of 1908, 28,460 of 1911 and 20,074 of 1912 (this J., 1909, 133 and 1913, 937), the decension pipe by which the vapours leave the horizontal or inclined retorts i which the oil is "cracked," passes down into a safety box from which the vapours pass to the condensin apparatus. When it is necessary to clean out the retort the end of the decension pipe is sealed by running wate into the safety-box, so preventing any flame from enterin the condensers. Steam connections are provided a the rear end of the retorts for blowing out the vapours after the doors have been slackened but before they are removed.—W. H. C.

Still [for petroleum]. C. L. Turner, New York, Assignor to S. H. Hart, Houston, Tex. U.S. Pat. 1,091,781, March 31, 1914.

The crude oil flows from a supply tank successively through a basin, a heater, a series of evaporators, and back to the supply tank. The evaporators each consist of a supply trough and a delivery trough, with an intervening spreading floor on which the oil is distributed in a thin layer; and are heated by radiators through which steam passes in a direction opposite to that of the oil. The steam supply to the radiators, one beneath and adjacent to the floor of each evaporator, can be independently regulated. The vapours from the evaporators pass to condensing coils, disposed within the basin, and serve to preheat the crude oil; means are provided for accelerating the passage of the vapours from the evaporators to the coils.—A. S.

Mineral oils, ozokerite, etc.; Removal of acid from —— after treatment with sulphuric acid. A. Burkhardt. Fr. Pat. 464,566, Oct. 7, 1913.

The crude oil, etc., after treatment with sulphuric acid, is heated and a current of air is passed through it until all sulphur dioxide is expelled. The temperature should not be high enough to cause any carbonisation. The oil is then allowed to stand, drawn off from the "acid tar," heated with a dehydrating agent such as calcium sulphate (calcined gypsum) to break down any emulsion of oil, water and tar, and then neutralised with alkali and refined in the usual way.—A. T. L.

Alcohols for industrial use; Carburetting —— during manufacture. G. Boulais and P. E. Lefèvre. Fr. Pat. 465,243, Jan. 31, 1913.

Alcohol for use in internal-combustion engines is enriched with acetylene, ethylene, or ether, in order to increase its calorific power. The alcohol vapours from the still are passed through layers of calcium carbide, whereby the alcohol is dehydrated and acetylene is generated and passes with the alcohol through the rectifying column and condenses with it in the receiver. The alcohol may in addition be saturated with oxygen and nitrous oxide, or preferably, with ethylene. The ethers which separate during distillation of the alcohol are freed from acids and mixed with the alcohol. Crude ether containing alcohol and water is also added in order to bring the alcohol to a standard calorific power.—A. T. L.

Coke; Utilisation of the waste heat of caked ——. C. Semmler, Wiesbaden, Germany. Eng. Pat. 23,274, Oct. 15, 1913.

See Fr. Pat. 463,299 of 1913; this J., 1914, 411.—T. F. B.

Gaseous mixture; Process and apparatus for producing combustible ——. A. Rosenberg. Fr. Pat. 464,357, Oct. 31, 1913. Under Int. Conv., Nov. 2, 1912.

See Eng. Pat. 25,165 of 1912; this J., 1913, 1149.—T. F. B.

Gas producer. T. de Fontaine. Fr. Pat. 464,549, Aug. 13, 1913. Under Int. Conv., Aug. 13, 1912.

Mineral oils; Method of treating ——. M. Melamid, Freiburg, Germany. U.S. Pat. 1,092,448, April 7, 1914.

See Eng. Pat. 5484 of 1913; this J., 1913, 1000.—T. F. B.

Mineral wax; Process for refining and decolourising ——. E. C. W. A. von Boyen, Barmstedt, Assignor to Wachs und Ceresinwerke zu Hamburg, J. Schlickum und Co., Hamburg, Germany. U.S. Pat. 1,092,629, April 7, 1914.

See Fr. Pat. 425,401 of 1911; this J., 1911, 882.—T. F. B.

Acid sludge and liquors produced as by-products during the washing of mineral oils; Process for working up the ——. W. Pau and P. Eberhardt, Grabow, Assignors to Rütgerswerke A.-G., Berlin. U.S. Pat. 1,092,386, April 7, 1914.

See Ger. Pat. 261,777 of 1911; this J., 1913, 904.—T. F. B.

Separating different kinds of minerals, such as coal, ores, etc. Eng. Pat. 26,418. *See* I.

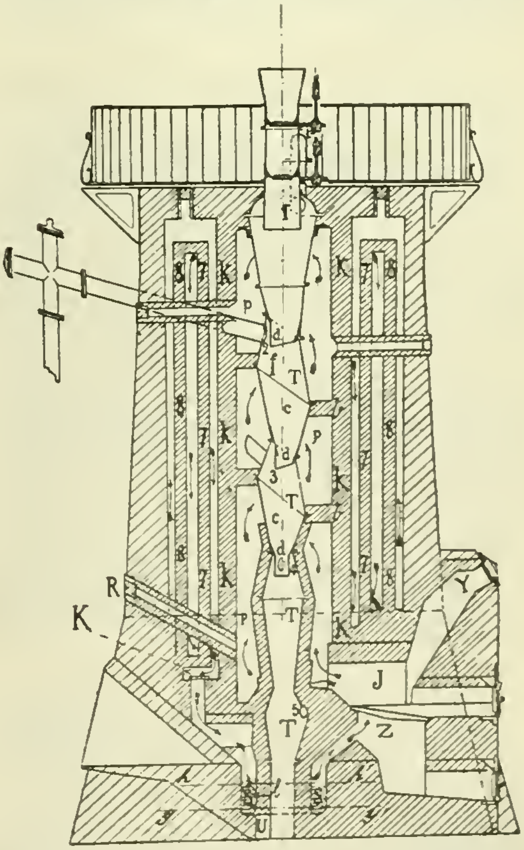
Manufacturing a binding or covering medium from waste sulphite lyes. Eng. Pat. 7324. *See* V.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Regenerative oven for carbonisation of peat, lignite, wood, sawdust and all solid fuels which do not swell when distilled, and for the recovery of by-products. G. Guardabassi and P. Goulliard. Fr. Pat. 464,591, Oct. 25, 1913.

A vertical retort is composed of elements, T, each consisting of two truncated conical portions such as *f*, *c*, having inclined, elliptical bases at both the larger and smaller ends. The longer axis of each large ellipse is in a different vertical plane, these planes all containing the



vertical axis of the retort and making equal angles with one another and a total angle of 360° from the lowest element to the uppermost. The two lowest elements are protected by firebrick, the others being of cast iron. The elements fit together at the small ends, and an extension-piece, *d*, is provided at the bottom of each to protect the gas outlets, 1, 2, 3, 4, 5. The peat, etc., passes downwards through the retort as the coke is gradually withdrawn from the chamber, *l*, at the bottom, and the gases from each element pass to separate condensers. The retort is heated by gases from the furnace chamber, J, where fuel is fed continuously on to the grate from an inclined chamber, Y. The hot gases circulate around the retort and then pass downwards between the walls, 7, 8, to the chimney. The air supply for the furnace chamber is drawn in at the bottom of the annular flue which surrounds the wall, 8, passes up and down the length of the retort and then through dampers, K, to the chamber, Z, beneath the grate. This chamber contains water normally at the level, h, h^1, and serves to generate steam for mixing with the air supply. In starting the retort, the water level is lowered to y, y^1, in order to admit air from openings normally sealed. This water also seals the opening, U, from which the coke is withdrawn, and serves to quench the coke, the steam and ammonia formed thereby passing to a condenser through the outlet, 5.—A. T. L.

Gas mantles; Manufacture of incandescent ——. J. I. Robin, London. Eng. Pat. 28,285, Dec. 8, 1913.

The fabric for making the mantles, whether upright or inverted, is knitted or woven from two or more threads, one or more of which is previously impregnated, whilst the remaining threads are not impregnated and are burnt entirely away during incineration. Unevenness of the fabric of the mantle after incineration is thus prevented. The different threads may be given distinctive colours.
—A. T. L.

Incandescence bodies [of boron] for electric lamps, furnaces, etc. E. Podszus. Fr. Pat. 464,552, Aug. 21, 1913. Under Int. Conv., Aug. 21, 1912.

Incandescence bodies or filaments of pure or almost pure boron are claimed. They may be formed from very finely divided boron nitride mixed with a suitable binder, which is removed by heating, the filaments being converted into pure boron by heating above 2000° C. in a current of ammonia. A small quantity of finely divided carbon may be added to act as a catalytic agent and facilitate decomposition of the nitride. Amorphous boron, which if pure and highly compressed, has a sufficiently low resistance, may also be used for preparing the filaments. It is obtained by the action of metallic vapours (mercury, copper, silver, sodium, calcium, etc.) on volatile compounds of boron, such as the chloride, sulphide or phosphide. For example, the vapours of pure boron chloride may be passed through a tube in which a long steady arc is maintained between electrodes of tungsten and mercury. Boron and mercury chloride are deposited on the cool parts of the tube, and the chloride is removed by heating.—A. T. L.

Distillation retorts; Feeding and distribution of charges in vertical ——. *Distillation of bituminous matters.* J. G. Aarts, Dongen, Holland. Eng. Pats. 17,611 and 17,661, July 31 and Aug. 1, 1913. Under Int. Conv., Aug. 1, 1912.

See Fr. Pat. 463,739 of 1913; this J., 1914, 412.—T. F. B.

Carbonaceous substances; Process for treating [destructive distillation of] ——. O. J. Parker. Fr. Pat. 465,262, Nov. 24, 1913. Under Int. Conv., Dec. 11, 1912.

See Eng. Pat. 28,582 of 1912; this J., 1913, 647.—T. F. B.

Charcoal powder; Process for making active ——. L. Pilaski, Warsaw, Poland. Eng. Pat. 19,228, Aug. 25, 1913.

See Ger. Pat. 267,443 of 1912; this J., 1914, 216.—T. F. B.

Charcoal; Manufacture of ——. O. Wright, Pennant Hills, N.S.W. U.S. Pat. 1,092,418, April 7, 1914.

Distilling crude pyroligneous acid. U.S. Pat. 1,089,417. *See* VII.

III.—TAR AND TAR PRODUCTS.

"Free carbon": its nature and determination in tar products. J. M. Weiss. J. Ind. Eng. Chem., 1914, 6, 279—285.

Results of experiments are described showing that benzene, toluene, chloroform, carbon bisulphide, and glacial acetic acid in contact with tar form insoluble compounds, the amount increasing with the period of contact: the residues obtained with chloroform and carbon bisulphide contained chlorine and sulphur respectively. No such insoluble compounds appeared to be formed with pyridine and aniline respectively, but these liquids are considered unsuitable as solvents for the determination of "free carbon," for which purpose digestion with toluene on a steam bath for not more than 30 mins. and extraction of the insoluble residue with benzene under standardised conditions is recommended. For asphaltums extraction with cold carbon bisulphide, using a Gooch crucible, is more rapid and gives results equally accurate.
—A. S.

Determination of the melting point of asphaltum. Schanin. *See* IIa.

Patents.

Coumarone-resin from heavy benzol of b. pt. 160°—180° C.; Production of a high-grade, pale ——. M. Wendriner. Ger. Pat. 270,993, Aug. 20, 1912.

The heavy benzol, after separation of tar acids and bases, is mixed with 3—5 per cent. by vol. of sulphuric acid of 60° B. (sp. gr. 1·71) and then treated, with continuous stirring, with, at the most, 0·25 per cent. by vol. of concentrated sulphuric acid, in a thin stream, until the temperature rises to 110°—120° C.; the acid (free from resin) is then separated, and the residual oil neutralised and distilled, whereby there are obtained a pale coumarone-resin and colourless solvent naphtha which has a pleasant odour and does not darken on exposure to light. It is not essential first to separate the tar acids and bases, but if this be not done, about 0·5 per cent. of concentrated sulphuric acid must be used, and the coumarone-resin obtained is not so pure.—A. S.

Diamino-di-p-xylylmethane from technical xylidine; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,663, Feb. 9, 1913.

The mixture of diaminodixylylmethanes, obtained by treating "technical" xylidine with formaldehyde, is converted into the hydrochloride, which is dissolved in water and decomposed by means of a soluble sulphate. The sulphate of diaminodi-*p*-xylylmethane, which is practically insoluble in water, is thus separated from th sulphates of the other bases.—T. F. B.

Condensation products of the anthraquinone series containin nitrogen; Process for preparing ——. Farbwerke vorm Meister, Lucius, und Brüning. Ger. Pat. 270,78 Dec. 14, 1912.

α-Anthraquinonylarylglycines (see Ger. Pat. 270,79 following) are treated with acetic anhydride. Yello

substances are obtained, which dissolve in alcohol and chloroform and exhibit a strong yellowish-green fluorescence. Their constitution has not been determined.
—T. F. B.

Condensation products of the anthraquinone series containing nitrogen ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Bruning. Ger. Pat. 270,790, Oct. 30, 1912.

α-Halogenanthraquinones or their derivatives or substitution products are heated with salts of aromatic glycines in presence of copper or its salts and of an indifferent solvent or diluent, at a temperature above 100° C. The products are anthraquinonyl derivatives of arylglycines of the general formula, $\mathrm{Aryl.N(R)CH_2.COOH}$, where R represents the anthraquinonyl nucleus.—T. F. B.

Tars from coal, petroleum or shales ; Conversion of —— into pitch by means of air under pressure. Soc. Anon. des Combustibles Industriels. First Addition, dated Jan. 4, 1913, to Fr. Pat. 443,207, July 8, 1911.

See Eng. Pat. 28,973 of 1912 ; this J., 1914, 246.—T. F. B.

Pitch ; Method of making a hard commercial ——. Barrett Manufacturing Co. Fr. Pat. 464,675, Nov. 8, 1913. Under Int. Conv., April 10, 1913.

IV.—COLOURING MATTERS AND DYES.

Indigo ; The process of oxidation of —— [by permanganate]. H. E. Wagner. J. prakt Chem., 1914, **89**, 377—414.

In the oxidation of indigo by permanganate, as is known, less of the oxidising agent is used than is required by theory for the conversion of indigotin into isatin, necessitating a correction of 12·6 per cent. This correction remained constant for concentrations above 1 : 4000 in the case of commercial synthetic indigo, or 1 : 5000 in the case of the natural product. The permanganate consumption was not affected by atmospheric oxygen, nor by addition of small quantities of manganese sulphate. When indigo solution was added, drop by drop, to acid permanganate, nearly theoretical results were obtained, whilst quicker addition caused an acceleration towards the old result. The excess of indigo used over the theoretical quantity could be raised to 12—13 per cent. by having present from the beginning an addition of isatin or isatinsulphonic acid. The author's experiments point to the formation of a labile primary oxide by the isatin or isatinsulphonic acid being the cause of the phenomenon, this oxide entering into the reaction and causing the acceleration which accounts for less than the theoretical amount of permanganate being required.—J. B.

Madder extract "Meissonier" ; Manufacture of ——. N. Bell. Bull. Soc. Ind. Mulhouse, 1914, **84**, 39—43.

This extract was manufactured by the firm of Meissonier according to the process of P. Schützenberger during the period 1867 to 1893. Garancine was extracted with hot benzene in a special form of reflux still and the solid, more or less crystalline product which separated on cooling was purified by dissolving in concentrated sulphuric acid, precipitating with water and washing free from acid.—J. B.

Examination of saffron. Krzizan. *See* XX.

Detecting magnesium sulphate in saffron. Nestler. *See* XX.

Patent.

Condensation products of the naphthazarin series and process for making them. Soc. pour l'Industrie Chimique à Bâle. Fr. Pat. 464,464, Jan. 13, 1913.

Naphthazarin or its homologues, analogues, or substitution products, or the substances obtained by heating these compounds with solvents or diluents, with or without addition of alkalis, alkali or alkaline earth sulphides or salts, or polyhydric alcohols (glycerol, etc.), are heated either with primary, secondary, or tertiary amines, or with thiophenols, or with compounds containing one of the groupings, $\mathrm{CH_2.CO}$ or $\mathrm{CH : C(OH)}$, such as indoxyl, oxythionaphthene, phenols, naphthols, anthranol, anthrol, etc., in presence of a solvent or diluent. Naphthazarins may be replaced by the corresponding arylido derivatives obtained by treating the naphthazarin with aromatic amines or their sulphonic or carboxylic acids. Similar compounds are obtained by heating these arylido derivatives of naphthazarin with a solvent or diluent, with or without an alkali, an alkali or alkaline-earth sulphide or other salt, or a poly-alcohol. All of these condensation products are readily converted into halogen derivatives. Some of the products obtained in this manner are dyestuffs, whilst others are suitable for use in preparing dyestuffs.
—T. F. B.

Furfuran derivatives, especially furfural ; Use of —— for producing black colouring matters. A. and E. Lederer. Fr. Pat. 464,622, Nov. 6, 1913. Under Int. Conv., March 11, 1913.

Derivatives of furfuran, especially furfural, are converted into substances which dye black shades on unmordanted fibres, by heating them with sulphur in presence of an alkali, an alkaline earth, or a metallic oxide such as lead oxide. For example, one part of caustic soda is dissolved in one part of water, one part of furfural is slowly stirred into the solution, one part of powdered sulphur is added, and the mixture is heated in an autoclave for two to four hours under a pressure of 3 to 5 atmospheres.—T. F. B.

Dyestuffs of the anthraquinone series ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 465,069, Nov. 19, 1913. Under Int. Conv., Dec. 5, 1912.

Acid dyestuffs for wool are obtained either by condensing anthraquinone-mercaptans with halogenated anthraquinonesulphonic acids, or by condensing anthraquinone-mercaptansulphonic acids with halogen-anthraquinones. The dyeings produced by these substances vary from yellow, red, brown, and violet to blue, and are distinguished by their fastness to chroming, fulling, and light.—T. F. B.

Disazo dyestuffs for cotton ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,669, Nov. 24, 1912. Addition to Ger. Pat. 257,193 (see third Addition to Fr. Pat. 376,888 ; this J., 1913, 131).

The monoazo dyestuff obtained by combining a diazo compound with *p*-aminobenzoyl-2.5.7-aminonaphtholsulphonic acid, is again diazotised and combined with 2.8.6-aminonaphtholsulphonic acid or its derivatives containing an acidyl group attached to the nitrogen.
—T. F. B.

Vat dyestuffs; Process for preparing blue ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat 270,885, Sept. 15, 1911.

Quinone or a halogen derivative of quinone is condensed with the mercaptans of *p*-aminodialkylphenylamines or their derivatives. When halogen-quinones are used, addition of sodium acetate is advisable. The condensation can be effected in presence of water, but the use of alcohol or glacial acetic acid is preferable. The products are easily converted into vats, in which cotton is dyed blue. —T. F. B.

Vat, pigment, and acid dyestuffs; Process for preparing yellow ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,943, June 18, 1911.

The condensation products obtained from indigo and benzoic anhydride or one of its derivatives according to Ger. Pat. 250,744 (see this J., 1912, 1025), are heated with condensing agents to high temperatures, with or without addition of a solvent or diluent.—T. F. B.

Dyestuffs of the fuchsin series; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,930, Jan. 10, 1912.

Aromatic glycines are fused with primary aromatic bases which do not contain an alkyl group in the *p*-position, or with their salts, in presence of aromatic nitrohydrocarbons and iron or an iron salt.—T. F. B.

Polyazo dyestuffs; Production of substantive ——. Fabr. de Prod. Chimiques ci-dev. Sandoz. Fr. Pat. 464,576, Oct. 16, 1913. Under Int. Conv., Feb. 12, 1913.

See Eng. Pat. 23,119 of 1913; this J., 1914, 415.—T. F. B.

Azo dyestuffs; Process for producing diazotisable ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 465,347, Nov. 26, 1913. Under Int. Conv., Dec. 27, 1912.

See Ger. Pat. 268,792 of 1912; this J., 1914, 195.—T. F. B.

New colour lakes. Eng. Pat. 15,557. *See* XIII.

Making azo dyestuffs containing the arseno group. Ger. Pat. 271,271. *See* XX.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Silk: Wild —— from Mexico. Bull. Imp. Inst., 1914, **12**, 45—47.

Wild silk is obtainable in large quantities in the States of Vera Cruz and Oaxaca, where the Indians use it for rope-making. The sample examined consisted of a flat loosely-spun web-like nest 12 by 18 in. The web, amounting to 24 per cent. of the whole sample, when separated as far as possible from extraneous matter, and degummed by boiling soap solution yielded a grey to greyish-brown silk of good lustre and strength. It is unlikely that the material could be used commercially owing to the low yield of degummed silk (about 10 to 15 per cent.), and the difficulties of cleaning and carding.—R. G. P.

Fibres from various sources. Bull. Imp. Inst., 1914, **12**, 32—42.

Jute from India. Four samples of jute grown experimentally at Dacca, Bengal, were examined with a view to determine the relation between strength and chemical properties. The strength as tested by hand was found to increase with increasing cellulose content and decreasing loss on hydrolysis.

Malachra capitata, *Urena lobata*, and *Sida* fibres from India would all be saleable as jute substitutes at prices close to those of "first marks" Calcutta jute.

"*Rama*" *fibre* from Northern Nigeria, is derived from *Hibiscus lunariifolius*, and it is said that an increasing quantity is now being shipped. One sample (*a*) was too harsh for use as a jute substitute and was valued at £12 per ton with "common" jute at £11—£12 per ton; the other (*b*) was valued at £16—£17 per ton as a jute substitute, with "first native marks" jute at £14 7s. 6d. per ton.

"*Crowa*" fibre from British Guiana, possibly from a species of *Ananas* or *Karratas*, was suitable for rope making and was valued at £24 per ton (Oct. 1909). The results of the chemical examination of some of the fibres are given in the following table :—

	Malachra capitata.		Rama.		Crowa.
	1	2	*a*	*b*	
	per cent.	per cent.	per cent.	per cent.	per cent.
Moisture........	11·1	10·8	8·5	10·5	9·9
Ash	0·8	0·4	0·4	0·8	0·6
α-Hydrolysis, loss	10·0	9·7	7·4	9·5	12·3
β-Hydrolysis, loss	15·0	13·3	10·2	12·8	16·1

Cellulose compounds; Analysis of ——. V. Hottenroth. Chem.-Zeit., 1914, **38**, 515.

In the determination of impurities (*e.g.*, sulphuric acid in cellulose acetate), destruction of the organic matter by hydrolysis with strong hydrochloric acid is recommended. After standing, hot, for several hours, the solution may be diluted without separation of hydrocellulose; the sulphuric acid is determined in the usual manner. —W. R. S.

Nitrocellulose; Viscosity of solutions of —— in alcoholic camphor solutions. H. Nishida. Caoutchouc et Gutta-percha. 1914, **11**, 8103—8115, 8200—8207.

The measurements were made with an Engler viscosimeter. Nitrocelluloses which were unstable or contained free acid had always a very low viscosity. The viscosity was increased by organic bases, fatty oils, fatty acids, and especially by phenol, whilst it was lowered by addition of various solvents (except camphor and camphor substitutes) to the alcohol, by aromatic acids, and by rise of temperature. After a certain time, long standing had no appreciable effect: the solutions did not "ripen" as did those of viscose. Cold washing of nitrocellulose, to remove free acid, raised the solubility and lowered the viscosity. Prolonged nitration usually gave nitrocelluloses of low viscosity, as did nitration at high temperatures, when the yield was poorer. The percentage of water in the nitrating acid was not of great importance, but 18 per cent. gave the best results. The ratio nitric : sulphuric acid was important; the ratio 0·25 : 0·35 gave the most viscous nitrocellulose. The nitrogen content of the nitrocellulose did not affect the viscosity. Bleaching often lowered the viscosity and tended to formation of oxycellulose. Treatment by metallic salts often affected the viscosity, which was usually lowered by any increase in stability. The viscosity of a nitrocellulose was higher, the lower the content of water. The viscosity of a mixture of two nitrocelluloses of known viscosities could be calculated from the additive law. These results show that viscosity measurements can be employed for purposes of control.—H. E. P.

Acetylnitrocelluloses and their utilisation for celluloid. H. Nishida. Kunststoffe, 1914, **4**, 141—142.

Three methods for the preparation of mixed acetonitric esters of cellulose were investigated. The nitration of cellulose acetate by the action of nitric and sulphuric acids is difficult practically owing to the dense structure of the acetic ester, and the products are not homogeneous. The acetylation of nitrocellulose in the form of tissue paper by an acetylating mixture containing sulphuric acid is practicable, but entails a loss of reagents, the gelatinous product absorbing acetic anhydride which can only be removed by washing. Starting with a nitrated paper containing 12·42 per cent. N, the author obtained a mixed ester, with a yield of 169 per cent., showing on analysis 4·8 per cent. N and 29·7 per cent. CH_3CO. The ester was only slightly inflammable. The best method for preparing these mixed esters was by simultaneous esterification by the "single bath" process. A whole series of esters of different compositions were obtained by varying the proportions of reacting acids. The most satisfactory product for celluloid manufacture was obtained with a mixture of concentrated sulphuric acid, 98 parts by vol.; nitric acid (1·5 sp. gr.), 52·5; acetic anhydride, 50. Six grms. of cotton wool were steeped in 300 c.c. of this mixture for 1 hour at 30° C. The product, which was obtained with a yield of 167 per cent., contained 9·8 per cent. N; it was completely soluble in alcohol and camphor, was non-inflammable by heating and only ignited by direct contact with a flame. When converted alone, or in admixture with nitrocellulose, into a celluloid mass, it yielded products more stable and less inflammable than ordinary celluloid.—J. F. B.

Pine waste; Chemical utilisation of southern ——. M. C. Whitaker and J. S. Bates. J. Ind. Eng. Chem., 1914, **6**, 289—298.

The results are given of laboratory tests of a method of utilising waste resinous wood (long-leaf southern pine, *P. palustris*) by digesting first with dilute caustic soda under a low pressure to extract the rosin and turpentine and then with stronger alkali under a higher pressure to convert the wood into paper pulp. The experiments were made with "box-face slabs" containing about 32 per cent. of rosin, 8·4 of volatile oils (turpentine and pine oils) and 5·2 per cent. of moisture. For the first digestion satisfactory results were obtained by working at 15—20 lb. pressure for 3½—4 hours and using about 7·2 per cent. of caustic soda (reckoned as Na_2O on the weight of wood) at a concentration of 1·5—2 per cent. Na_2O. Most of the oil of turpentine was obtained in the first hour and without excessive consumption of steam: the condensed oil became heavier as distillation proceeded, so that it would be possible to effect directly a preliminary fractionation into "wood turpentine" and "pine oil." After draining off the dilute alkaline liquor, the residual "chips" were washed by boiling for a short time with water, and rosin soap was "salted" out from both the alkaline liquor and the wash liquor by adding caustic soda so as to bring the concentration up to 6—8 per cent. From 75 to 85 per cent. of the rosin contained in the wood was recovered in the form of rosin soap, which after purification by dissolving in water and re-precipitation with caustic soda, could be used directly for the preparation of size. The liquor was decanted or siphoned from the rosin soap precipitate and used in the subsequent digestion for converting the resin-free wood into paper pulp. This second digestion was effected at 100 lb. pressure for 2¼—4 hours, using 16½—35 per cent. of caustic soda (reckoned as Na_2O on the weight of wood) at a concentration of 1·8—4·2 per cent. Na_2O: about 25 per cent. of pulp (reckoned on the raw wood), of good strength and flexibility, composed of fibres 4—6 mm. long, was obtained. —A. S.

Nipa palm leaves for paper-making. Bull. Imp. Inst., 1914, **12**, 42—44.

The midribs of the leaves of the nipa palm from Sarawak yielded 33 per cent., while the leaves alone only yielded 20 per cent. of unbleached pulp calculated on the material dried at 100°—110° C., compared with 32·3 per cent. from Algerian esparto grass. The ultimate fibres of the midribs were equal in average length to those of esparto grass, those from the leaves were shorter. Both the midribs and leaves could be readily converted into a brown pulp which yielded fairly good paper. Though too bulky and giving too small a yield of pulp to allow of export to Europe, it might be possible to use them locally in Sarawak for paper-making or for the manufacture of "half-stuff" for export.—R. G. P.

Scilla rigidifolia leaves from Swaziland (for paper-making). Bull. Imp. Inst., 1914, **12**, 44—45.

Scilla rigidifolia grows in large quantities in Swaziland and the leaves contain a fair amount of fibre, which is, however, weak and could not be extracted profitably for textile use. The leaves yielded 35·4 per cent. of unbleached pulp calculated on material dried at 100°—110° C., compared with 32·3 per cent. from Algerian esparto grass; the ultimate fibres of *S. rigidifolia* were shorter than those of esparto grass. The leaves might be used locally in S. Africa for the manufacture of pulp.—R. G. P.

PATENTS.

Wool or other fibrous substances, skins, hides or textile fabrics; Method of treating —— to destroy anthrax or other disease germs. W. Rhys-Davies, Bradford. Eng. Pat. 5924, March 10, 1913.

Liquid or gaseous formaldehyde is injected by means of superheated steam or hot compressed air through the material, which is contained in a steam-jacketed chamber having a perforated false bottom, and filled with carbon dioxide. (Reference is directed to Eng. Pat. 23,954 of 1907; this J., 1908, 1173.)—J. F. B.

Textile fibres; Process of treating —— with soap-baths in the form of froth, particularly for the degumming of silk. C. Ris. Fr. Pat. 464,969, Nov. 15, 1913. Under Int. Conv., Nov. 22, 1912.

In treating fibres in a bath of froth from a boiling soap solution the operation is carried out in a closed vessel under reduced pressure, at a temperature below the normal boiling point of the liquid.—J. F. B.

Wicks for candles, wax matches, tapers and the like; Manufacture of ——. A. Wilson, London. Eng. Pat. 5170, Dec. 23, 1913.

The wicks are prepared from filaments or threads of cellulose produced from a solution of viscose by squirting it into a solution of sulphuric acid of about 10 per cent. strength.—J. F. B.

Cellulose or the like; Apparatus for pumping or regulating the flow of solutions of ——. J. E. Criggal, Wolverhampton. Eng. Pat. 9758, Apr. 25, 1913.

The apparatus is of the type in which two or more revolving cylinders are employed, the operative strokes of the plungers of which are effected by a stationary cam. The gearing for rotating the disc carrying the pump cylinders is arranged to permit of the easy removal of the disc. —J. F. B.

Artificial silk; Machines for spinning ——. V. Martin, Lille, France. Eng. Pat. 18,680, Aug. 16, 1913. Under Int. Conv., Aug. 16, 1912.

A number of thread-drums are mounted on a vertical or horizontal rotatable member, each drum being provided with a vertical shaft and friction cone. When one of the drums is full, the member is rotated and another drum comes under the spinning guide from which the thread is being delivered; at the same time the cone on the shaft of the new drum engages with the friction disc of the main driving shaft and the drum revolves, the friction disc being held in engagement by a spring mechanism.—J. F. B.

D

Cellulose esters and products derived from them; Manufacture of ——. Farbenfabriken vorm. F. Bayer und Co. First Addition, dated Oct. 21, 1913, to Fr. Pat. 417,274, June 18, 1910. Under Int. Conv., Oct. 31, 1912 (this J., 1911, 19).

For the preparation of cellulose acetates soluble in acetone, the acid sulphates of primary aromatic amines (*loc. cit.*) may be replaced by neutral sulphates of amines. Example: 50 parts of cellulose are acetylated by a mixture of 250 parts of acetic anhydride, 200 of glacial acetic acid and 20 of methylamine sulphate or *o*-toluidine sulphate, at 30°—60° C.—J. F. B.

Plastic masses; Manufacture of extra-supple ——. Soc. Anon. Nouvelle L'Oyonnithe. Fr. Pat. 465,345, Nov. 26, 1913.

Extra-supple plastic masses of a basis of nitrocellulose or cellulose acetate are made by incorporating with the usual solvents a very high proportion (50—70 per cent. of the weight of cellulose ester) of castor oil, "manol," acetin, etc., with or without pigments or metals, the material being prepared in sheets not exceeding 2 mm. in thickness. Textile fabrics may be combined with these sheets on one or both sides.—J. F. B.

Lignocelluloses; Separation and recovery of volatile acids, methyl compounds and furfuran bodies from hydrolysed ——. A. and E. Lederer. Fr. Pat. 464,608, Jan. 16, 1913.

The volatile products formed in the hydrolysis of lignocelluloses are removed by distillation under pressure from the mass in course of hydrolysis. The condensed liquid is fractionated by subsequent distillation, volatile acids, furfural, methyl alcohol and acetone being obtained. The volatile products still remaining in the hydrolysed mass are separated by drying the latter *in vacuo* at not above 80° C. until it contains only 5—10 per cent. of moisture. No destruction of sugar takes place at this temperature, but if a higher temperature be desired, calcium acetate may be added to neutralise the mineral acid present.—J. F. B.

Pulp for the manufacture of paper; Means and method of bleaching ——. P. Couper, Oakenholt, Flints. Eng. Pats. 9442 and 20,355, Apr. 22 and Sept. 9, 1913.

Dilute pulp from a tank is passed through a concentrator, whence the concentrated pulp is conveyed on a band to a funnel in the cover of a second tank, having a conical copper hood concentrically mounted near the top for distributing the flow of pulp uniformly. When the second tank is charged with pulp and bleach liquor, the funnel is removed, the cover closed and the pulp circulated from the bottom of the tank to the top of the copper hood by means of a pump and pipe outside the tank. During this process compressed air is admitted to the closed tank so that bleaching takes place under pressure. Subsequently the bleached stock is pumped over into a series of open tanks of similar construction, from which it is passed to a second concentrator.—J. F. B.

Paper and the like; Manufacture of —— [*regulation of flow of pulp*]. J. H. Wallin, Kopmanholmen, Sweden. Eng. Pat. 26,242, Nov. 15, 1913.

Variations in the quantity of water running from or pressed out of some part of the wet portion of the paper-machine are caused to act upon a registering device for indicating the thickness of the pulp or upon a regulating device for controlling the supply of pulp to the machine. For instance, the water flowing from the first wet press is collected and delivered through a flexible tube into a vessel provided with an outlet near the bottom. The size of the outlet in relation to the inlet is so adjusted that variations in the rate of water entering the vessel produce variations in the height of the water in the vessel. These variations act upon a float which in rising and falling operates an indicating lever showing the thickness of the pulp. This lever may constitute a movable electric switch, closing in its two extreme positions two separate electric circuits which cause the engagement of one or other of two pawls on a reciprocating rail with a ratchet wheel controlling the supply of pulp.—J. F. B.

Paper, pulp and similar mills; Apparatus for clarifying the back-waters of ——. E. Mann und Co. Fr. Pat. 464,483, Nov. 6, 1913. Under Int. Conv., Nov. 7, 1912 and Jan. 27, 1913.

The settling apparatus consists of two tanks arranged one behind the other and communicating with each other at their lower portions. The back-waters enter the first tank, which is of great length and has a slightly inclined front wall. The second tank, which serves for the discharge of the clarified water, is enlarged towards the top in the form of a hopper. The wall which forms the partition between the two tanks is inclined towards the end at which the liquid enters, and its angle of inclination may be altered. The back-waters entering the first tank may be directed downwards in a thin, wide stream by a baffle-plate situated near the point of entry.—J. F. B.

Bookbinding material; Production of waterproof ——. B. Hansel, Vienna. Eng. Pat. 23,957, Oct. 22, 1913.

The fabric is impregnated with a paste prepared from starch which has been hydrolysed by the action of cold alkalis or acids, and is then treated with a dilute solution of oil-varnish lacquer before applying a waterproof coating (*e.g.* nitrocellulose).—J. F. B.

Waste sulphite lyes; Process for manufacturing a binding or covering medium from ——. P. G. Müller, Berlin-Friedenau, Germany. Eng. Pat. 7324, Mar. 27, 1913.

Waste lyes from the manufacture of sulphite cellulose are concentrated and then incorporated by prolonged stirring with carbon bisulphide; the material is suitable for use as a varnish, paint, covering or binding medium for briquettes. In the manufacture of coal briquettes with this material, oil, resin, wax, paraffin, camphor, etc., may be added with the carbon bisulphide in the dissolved state, as a protection against moisture and disintegration in the fire.—J. F. B.

Retting of flax and like straws. W. J. Fernie, Newark-on-Trent. Eng. Pat. 11,384, May 13, 1912.

See Fr. Pat. 460,092 of 1913; this J., 1914, 19.—T. F. B.

Wool or similar substances; Process for degreasing raw —— *by means of fat solvents.* C. Netz und Co., and F. Koch. Fr. Pat. 464,400, Nov. 4, 1913. Under Int. Conv., Feb. 14, 1913.

See Ger. Pat. 267,487 of 1913; this J., 1914, 72.—T. F. B.

Washable materials having little or no flammability, and process for obtaining same. A. Eichengrün, Berlin. Eng. Pats. 7418, March 28, 1913 (under Int. Conv., April 9, 1912), and 7899 of 1914, date of appl., March 28, 1913.

See Fr. Pat. 455,811 of 1913; this J., 1913, 939.—T.F.B.

Paper pulp and liquids containing suspended matter; Centrifugal apparatus for purifying —— H. N. Fearnley and B. Geen. Fr. Pat. 464,660, Nov. 8, 1913. Under Int. Conv., Nov. 11, 1912.

See Eng. Pat. 25,849 of 1912; this J., 1913, 1104.—T.F.B.

Briquetting coal with waste sulphite-cellulose lyes and an inorganic substance. Ger. Pat. 271,479. *See* IIa.

Production of glucose and ethyl alcohol from sawdust or othe cellulosic material. Fr. Pat. 464,502. *See* XVIII.

Production of organic solvents [for nitrocellulose]. Eng Pat. 29,963. *See* XX.

VI.—BLEACHING ; DYEING ; PRINTING ; FINISHING.

Chromium oxide ; The destructive action of bleaching liquor on cotton containing ——. W. Thomson. J. Soc. Dyers and Col., 1914, **30**, 142—143.

A cloth containing two sets of black threads dyed Aniline Black by different dyers was found after bleaching to have become tendered in one set of black threads but not in the other. Analysis showed that the tendered threads contained an excessive amount of chromium oxide. Experiments with cloth on which varying amounts of chromium oxide had been fixed, showed that bleaching produced a degree of tendering roughly proportional to the amount of chromium on the fibre. Copper had a still more injurious influence on cotton in the presence of bleaching powder solutions. In the discussion it was stated that goods dyed with Green's Aniline Black, which contained a high proportion of chromium, did not tender in schreinering.—J. B.

Wool ; The development of the amino group in ——. C. M. Whittaker. J. Soc. Dyers and Col., 1914, **30**, 149.

After prolonged exposure to light wool has an increased affinity for basic dyestuffs, a generally decreased affinity for acid dyestuffs and cannot be so readily diazotised and combined with a-naphthylamine. The results would appear to indicate that the amino groups in wool are destroyed by the exposure, but this is opposed to the experience of garment dyers, who find that faded portions of garments always come out darker in re-dyeing.—J. B.

Neutral salt reactions with reference to their influence in the acid dye-bath. A. Herz and C. E. Barraclough. J. Soc. Dyers and Col., 1914, **30**, 135—141.

The authors dispute the work of Fort on the neutral salt reaction and its application to explain the tendering of unions dyed in the piece in the neutral Glauber's salt bath (see this J., 1913, 359, 483). Both pure sodium sulphate crystals and carefully cleaned wool gave an alkaline reaction with cochineal as indicator. Even with alizarin wool showed an alkaline reaction and experiments with wool, alizarin and sodium sulphate gave results contrary to those obtained by Fort. The supposed decomposition of Glauber's salt by wool, with absorption of the sulphuric acid by the latter, was disproved by quantitative experiments ; wool boiled with a solution of Glauber's salt under a reflux condenser absorbed no sulphuric acid. The experimental results of Lloyd (this J., 1912, 1076) by which he attempted to explain the tendering of cotton warps in lustre union goods which were dried without complete removal of the bath liquor (sodium sulphate and an inorganic acid) could not be confirmed. Patterns kept over the week-end at 70° C. were not tendered, and only the most minute traces of sulphuric acid could be detected. Lloyd's statement that nitric acid is produced by boiling potassium nitrate and acetic acid in the presence of wool was not confirmed. In the discussion the authors' criterion of purity for the wool experimented on was criticised. It was also argued that in a solution containing an organic acid and a neutral salt of a mineral acid a certain amount of mineral acid must be produced according to the dissociation constant. In the presence of wool this production of mineral acid would tend to increase owing to preferential absorption of the mineral acid by the wool.—J. B.

Naphthol AS and its application in dyeing and printing. F. Kunert and E. Acker. J. Soc. Dyers and Col., 1914, **30**, 128—134.

Naphthol AS is an arylide of 2.3-hydroxynaphthoic acid (see Eng. Pat. 17,279 of 1913 ; this J., 1914, 73), and by using it in conjunction with various diazo compounds brilliant dyeings of all shades except a pure yellow and green can be produced on yarn, cops, cheeses, pieces, etc. in a manner similar to that used in the case of β-naphthol, over which it possesses great advantages in the greater fastness of the dyeings and in the ease of its application. A feature of its application is the omission of drying after padding (except in the case of piece goods), this being possible on account of the quickness of combination with the diazo compound and also because of the substantive-dyeing properties of the Naphthol AS. The method of application varies in detail for the different developers (nitranilines, nitrotoluidines, nitroanisidines, dianisidine, etc.) and a special form of Obermaier apparatus is recommended. Piece dyeing requires special precautions and drying is necessary, preferably in the hot-flue, after preparing. There is no risk of sublimation as with β-naphthol. In printing the new process can be applied in any of the styles usual for the β-naphthol process. Dianisidine Blue produced with Naphthol AS or with a newer product, Naphthol NA, which gives redder shades, is particularly interesting for discharge work. Pinks can be produced which surpass Alizarins in brilliancy. All the shades appear to be fast to bleaching ; it is claimed that the blue from dianisidine is faster even than Hydron Blue to chlorine. The fastness to rubbing is good and the fastness to light of some of the reds approaches that of Alizarin. A black, obtained by developing separately with the Fast Orange R Base and with dianisidine, is said to be faster to chlorine than Indanthrene Black. Generally the new colours will not stand pressure in kier boiling.

—J. B.

Dianisidine Brown (Ortamine D Brown). H. Schmid. Bull. Soc. Ind. Mulhouse, 1914, **84**, 44—51.

The brown is produced by padding with o-dianisidine (Ortamine D) dissolved in hydrochloric acid and formic acid together with sodium chlorate and a small quantity of an activator, *e.g.*, potassium ferrocyanide or ferrous sulphate. The goods are dried, printed with the ordinary reserves for Paramine Brown, steamed three to five minutes in the small Mather and Platt, and finally degummed in a dilute bath of Solvay salt (sodium carbonate) at 50° C., washed and soaped. Tendering is avoided by the use of the formic acid in the place of part of the hydrochloric acid necessary for solution of the base. Vanadium cannot be used as a catalyst as it causes premature oxidation. By the use of considerably larger quantities of potassium ferrocyanide than are necessary for the production of the ordinary Ortamine Brown, the shade is considerably changed, becoming brighter and ranging in tone from reddish brown to maroon and orange-brown. The more ferrocyanide is used the more orange the shade. This property allows of the printing of semi-reserves, *i.e.*, after padding with the ordinary Ortamine liquor containing a small amount of ferrocyanide, a paste containing more ferrocyanide is printed. White reserves are obtained readily, for example, with a mixture of Rongalite C, potassium sulphite and sodium acetate. Illuminated effects can be produced by printing a mixture of sodium chlorate and potassium ferrocyanide on cloth padded with a mixture containing a large proportion of ferrocyanide. Dark brown effects are thus obtained on a lighter, orange-brown ground. Ortamine D can be employed in printing silk and half-silk.—J. B.

Printing ; A new fixing agent for use in ——. L. Baumann, G. Thesmar and S. M. Jones. Sealed note No. 2204, dated Sept. 18, 1912. Report thereon by M. Battegay and F. A. M. Noelting. Bull. Soc. Ind. Mulhouse, 1914, **84**, 52—56.

The new fixing agent is the condensation product formed by heating phenol and formaldehyde in the presence of a condensing agent, *e.g.*, sodium carbonate, sulphite, hydrosulphite, phosphate, acetate, etc. The resulting viscous yellow fluid is printed together with the metallic powder or colouring matter and an addition such as acetin. The print is fixed by steaming in the small Mather and Platt for four minutes, or by treating for one hour in a large steamer, finally soaping. (Compare M. J. Stéphan, this J., 1913, 422, and J. Heilmann et Cie., H. Wagner and M. Battegay, this J., 1913, 696.)—J. B.

Silk; The fading [discolouration] of dyed ——. A. Jones and G. W. Parr. J. Soc. Dyers and Col., 1914, **30**, 147—149.

The discolouration took place in pure silks on storage in diffused light or in the dark, reddish brown spots (the "red spotting" of Sisley; see this J., 1902, 1328) being usually produced. The discolouration was always followed by tendering and was attributed to oxidation, restoration both in appearance and in strength resulting when the fault was treated with reducing agents, *e.g.*, hydrosulphite, sulphurous acid or Rongalite (sodium formaldehyde sulphoxylate). Three factors were always present—traces of iron or copper, sodium chloride and "scroop acid." Free acid was always found in the discoloured places in greater amount than in normal places. The immediate cause was assumed to be the dissociation of sodium chloride and oxidation of the liberated hydrochloric acid to chlorine by means of atmospheric oxygen. Generally speaking the amount of tendering was proportional to the amount of sodium chloride present, and copper was a much more effective catalyst than iron. A similar destruction of wool takes place during bleaching by means of hydrogen peroxide in the presence of a copper or iron catalyst (see Lloyd, this J., 1913, 908).—J. B.

Fastness to light of dyed cotton; Influence of finishing on the ——. E. Schmidt and B. Gabler. Färber-Zeit., 1914, **25**, 153—155.

An investigation of the effect of various additions to the finish on the fastness to light of direct cotton dyestuffs (compare Jones, this J., 1910, 752). The effect varies with different dyestuffs but by careful choice of the dressing it is possible considerably to increase the fastness to light of many cheap direct dyeings. The additions found to have the most marked effect are aluminium sulphate, sodium metaphosphate (see Ger. Pats. 255,117 and 257,876; this J., 1913, 360 and 484), and aluminium thiosulphate. These increase in a remarkable manner the fastness to light of such dyestuffs as Diamine Pure Blue FF, Diamine Blue BX and Columbia Brown R. Sodium thiosulphate (see Fr. Pat. 455,804; this J., 1913, 940) and sodium phosphate also have a good effect. A dextrin finish is recommended as most suitable, whilst "Apparatin" (a starch preparation) had a harmful effect, despite additions. In the main alkaline finishes have a negative effect. Finishes prepared from soluble starch vary according to the method of rendering the starch soluble; the use of perborate and formic acid gives the best products. The best result in the experiments was obtained with a dressing of starch (rendered soluble by perborate or formic acid), glucose, glycerin, salt and aluminium sulphate or sodium metaphosphate. Similar dressings increase the fastness of the fugitive Sulphur Browns, of basic dyestuffs, and of direct dyeings topped with basic dyes.—J. B.

Patents.

Mercerisation; Process and apparatus for —— *and for the recovery of the caustic soda.* W. Brächter. Fr. Pat. 464,730, Nov. 10, 1913. Under Int. Conv., Nov. 14, 1912.

A process for the continuous recovery of the mercerising lye, the cloth being passed under tension through a series of superposed horizontal baths through which flows a stream of warm water in a direction contrary to that of the cloth. A concentration of 12° to 15 B. (sp. gr. 1·091—1·116) can be attained in the last bath.—J. B.

Dyeing and bleaching textiles; Apparatus for ——. P. M. Havez. First Addition, dated Oct. 3, 1913, to Fr. Pat. 438,504, Dec. 27, 1911.

A variation on the method of building up the stacks of bobbins on the plate of the dyeing machine described in the principal patent (this J., 1912, 637). Instead of conical tubes for the bobbins, which slide each into the tube below it, cylindrical tubes are used, connected with each other by means of flanges, or by making alternate tubes slightly narrower than the ones above and below.—J. B.

Green dyeings; Process for producing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 270,661, Dec. 6, 1911.

A tetrazotised diamine is combined on the one hand in acid solution with 1.8-aminonaphthol-3.6- or -4.6-disulphonic acid and on the other with a primary or secondary amine; when textile fibres are dyed with these products and developed with a diazo compound, very fast green dyeings are produced, which can be discharged to pure white.—T. F. B.

Sarees, scarves, shawls and the like; Machines for printing ——. The Calico Printers' Assoc. Ltd., Manchester, and J. Muir, Glasgow. Eng. Pat. 10,962, May 9, 1913.

In machines in which a separate timing cam plate and timing shaft are employed for each tappet shaft, each timing cam plate is formed in two or more parts, one of which is graduated and adjustable relatively to the others, and is set relatively to the zero timing cam, for the purpose of changing the respective motions when a change is made in the length of the article to be printed.—J. F. B.

"*Col marin et divers*"; *Application of* —— *to cotton fabric by printing.* A. Louppe et fils. Fr. Pat. 465,108, Oct. 25, 1913.

Covers the application of "*Col marin et divers*" to cotton fabrics by printing (roller or block) in direct or discharge styles.—J. B.

Brown or grey prints on vegetable fibre; Process for producing fast ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,252, Jan. 24, 1913.

The goods are printed with a caustic alkaline solution of an aminonaphthol, which may also contain formaldehyde, acetone, or alcohol, and the colour is developed by steaming or by suspending in the air. The shades may be deepened by after-treatment with bichromate. Formaldehyde accelerates the formation of the dyestuff and thus reduces the time of development, whilst the addition of acetone or alcohol keeps the printing colour fluid for a longer time.—T. F. B.

Metallisation of sheets, films or threads of cellulose; Process of ——. E. Crumière et Cie. Fr. Pat. 464,344, Jan. 10, 1913.

The cellulose material (cotton, linen, etc., or artificial cellulose) is coated with a solution of a natural or artificial resin in oil of turpentine or other solvent (*e.g.* benzene) with which is mixed the metallic powder. A softener, for example dicresyline, may be added.—J. B.

[*Waterproofing*]. *Treatment of fabrics and other materials with viscous substances and means therefor.* A. M. Hart, London. Eng. Pat. 18,279, Aug. 11, 1913.

In a machine for applying viscous or semi-liquid substances to fabrics, paper, etc., the scraper consists of several edges of different cross-section, and is mounted so that when turned on its axis any one of the edges may be brought into use. The edges have a hollow space running along their length through which a heating fluid can be circulated.—J. B.

Dressings [*for textiles, etc.*] *stable towards water and moisture Process for preparing* ——. E. T. J. Watremez. Ger. Pat. 271,251, Jan. 26, 1913.

Chromed gelatin treated with sulphurous acid is used alone or with other dressings, for application to texti fabrics, paper, wood, and leather; the chromed gelati is fixed on the goods by drying.—T. F. B.

Finishing material from gelatin, resistant to water. E. T. J. Watremez. Fr. Pat. 464,729, Nov. 10, 1913. Under Int. Conv., Nov. 11, 1912, and Jan. 11, 1913.

See Ger. Pat. 271,251 of 1913; preceding. When soap is added to the finishing bath, it combines with the chromium, forming a metallic soap which improves the resulting finish.—T. F. B.

Brown shades on fibre; Process of producing ——. H. Schmid, Mülhausen, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,092,542, April 7, 1914.

See Fr. Pat. 447,991 of 1912; this J., 1913, 423.—T. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid manufacture; The chamber process of ——. W. Hempel, F. Heymann, J. Richter, and Hering. Z. angew. Chem., 1914, **27**, 218—223.

Experiments by Richter showed that in the determination of nitrous oxide in gaseous mixtures, the method used by Hempel and Heymann (this J., 1906, 845) gave high results and the method of Inglis (this J., 1904, 643; 1906, 149; 1907, 668) low results. Percentages of nitrous oxide ranging from *nil* up to 0·012 per cent. were found in the gases from chambers working normally at Muldenhütten, but the higher values found previously by Hempel and Heymann (*loc. cit.*) were undoubtedly due to irregular working. Experiments in a small glass apparatus in which mixtures of sulphur dioxide, oxygen (air) and steam were allowed to interact in presence of different oxides of nitrogen, and at different temperatures, showed that the reaction was more rapid with N_2O_3 (dissociated into NO_2 and NO) than with N_2O_4, indicating that the process is not one of simple oxidation, but that an intermediate product is formed. The reaction proceeded more readily the larger the proportion of steam and of nitrous gases present, and with a high concentration of nitrous gases the best temperature was 70° C.; in this last set of tests the gas mixture consisted of approximately 9·67 c.c. SO_2, 27·32 c.c. H_2O, 61 c.c. air, and 10·39 c.c. NO. With a large excess of sulphur dioxide *e.g.* with a mixture of 240 c.c. SO_2, 15·9 c.c. NO, and 10 c.c. H_2O, after 24 hours at 73° C., nearly all the nitric oxide was reduced to nitrous oxide and nitrogen was not formed or at the most only in very small quantity.—A. S.

Arsenic acid; Reduction of —— to arsenious acid by thiosulphuric acid. R. M. Chapin. J. Agric. Res., 1914, **1**, 515—517.

Arsenic acid is reduced to arsenious acid by a mixture of sodium thiosulphate and mineral acid, the reaction being quantitative in 2½—7½ mins. with the following quantities:—10 c.c. of $N/10$ solution of arsenic acid, 15 c.c. of water, 20 c.c. of $N/10$ thiosulphate and 10 c.c. of $N/10$ hydrochloric acid. After addition of a little potassium iodide, the excess of thiosulphate is titrated with $N/20$ iodine, then sodium carbonate is added, and the arsenious oxide titrated with $N/20$ iodine. The formation of tetrathionic acid appears to be the essential reaction of the reduction with thiosulphuric acid. If the mixture, after the second titration, is heated with sodium carbonate a quantity of thiosulphate, nearly equal to that originally added, is formed (cp. Stiasny and Das, this J., 1912, 755). The reaction is not suitable for accurate work, but may serve for approximate determinations of arsenic, *e.g.*, in arsenical baths used for dipping cattle, and for reducing arsenic to arsenious acid prior to precipitation with hydrogen sulphide.—L. E.

Telluric acid; Preparation of ——, and a test for associated tellurous acid. P. E. Browning and H. D. Minnig. Amer. J. Sci., 1913, **36**, 72.

Telluric acid can be prepared by passing chlorine into water holding amorphous tellurium in suspension. The element slowly dissolves, and when a portion of the solution, after rendering alkaline, ceases to give a precipitate on acidification with acetic acid. When a precipitate is no longer formed in this test, the oxidation to telluric acid is complete. The test will detect one part of tellurous acid in presence of 200 parts of telluric acid. From the solution the telluric acid is obtained in crystalline form by precipitation with acetone or ethyl alcohol.—C. F. M.

Ammonia-soda process; A new theory of the ——. W. Mason. Chem.-Zeit., 1914, **38**, 513.

When carbon dioxide is passed through the ammoniacal solution of sodium chloride, a precipitate of sodium carbonate is sometimes formed. It is suggested that the reaction: $2NaCl+(NH_4)_2CO_3=Na_2CO_3+2NH_4Cl$ takes place; in concentrated solution a certain amount of sodium carbonate would separate as such, the bulk being precipitated as bicarbonate on further treatment with carbon dioxide.—W. R. S.

Potassium trioxide and the stability of alkali peroxides. R. de Forcrand. Comptes rend., 1914, **158**, 991—994. (See also this J., 1914, 419.)

Potassium trioxide is most readily obtained by heating the tetroxide (K_2O_4) to 480° C. *in vacuo*. Dissolved in excess of dilute sulphuric acid to form potassium hydrogen sulphate, hydrogen peroxide, and oxygen it evolves 43·554 Cals. per grm.-mol. which gives for its heat of formation from its elements 124·336 Cals., and from potassium monoxide and oxygen 37·536 Cals. When it is converted into K_2O_4 9·404 Cals. per grm.-mol. are evolved. The reaction $K_2O+O=K_2O_2$ is thus accompanied by the evolution of about 22 Cals. Comparison of these results with similar ones for oxides and peroxides of the other alkali and alkaline-earth metals indicates (1) that the heats of formation of the trioxides of sodium, potassium, rubidium, and cæsium are all about 126 Cals., and (2) that the heat of reaction in the conversion of monoxide into dioxide increases in the following order:—Calcium 4·11, lithium 7·97, strontium 13·07, barium 18·36, radium 18·7, sodium 19·03, potassium 22·0, rubidium 24·1, cæsium 25·0 Cals.—W. H. P.

Aluminium hydroxide; Acidic and colloidal properties of ——. R. E. Slade and W. G. Polack. Faraday Soc., April 22, 1914. [Advance proof.]

Following criticism of the work of Mahin, Ingraham, and Stewart (J. Amer. Chem. Soc., 1913, **35**, 30), who concluded that aluminium hydroxide has no acidic properties and that so-called solutions of sodium aluminate are really colloidal solutions of aluminium hydroxide in sodium hydroxide, conductivity experiments with solutions of sodium aluminate of different concentrations and at different temperatures are described. The change of conductivity as hydrolysis proceeded proved, as previously shown by Hantzsch (Z. anorg. Chem., 1902, **30**, 289) that aluminium hydroxide behaves as a monobasic acid, but no evidence could be obtained of the formation of colloidal aluminium hydroxide as the first stage of the hydrolysis, as suggested by Hantzsch; whenever hydrolysis took place crystalline aluminium hydroxide was deposited. When examined in the ultra-microscope sodium aluminate solutions showed about the same number of sub-microns as did the sodium hydroxide solution from which they were prepared, but no definite conclusions as to the presence or absence of colloidal aluminium hydroxide could be drawn from this, since in colloidal aluminium hydroxide solution prepared by Crum's method of hydrolysis of aluminium acetate, the number of sub-microns was of about the same order, the colloid being mainly in the form of amicrons.—A. S.

Alumina; Precipitation of —— in presence of fluorides. H. Cavaignac. Comptes rend., 1914, **158**, 948—950.

In presence of fluorides, alumina is not completely precipitated by ammonia. Thus, from a solution of ammonium aluminium fluoride, ammonia precipitates only 84—98·6 per cent. of the alumina at the ordinary temperature and less than half at 100° C. The precipitate, also, is contaminated with fluoride.—L. E.

Explosion of acetylene [from calcium cyanamide] in Trieste Harbour. G. Morpurgo. Mitt k. k. Techn. Versuchsamtes, 1914, **3**, 60—62.

A report on a violent explosion which occurred on Jan. 17th last, on a ship having on board 600 sacks of calcium cyanamide. Eight samples of the calcium cyanamide yielded, on treatment with water, quantities of acetylene corresponding to from 1·28 to 9·35 per cent. of calcium carbide. The hold in which the sacks were stored was only half full and was not ventilated, and the explosion was evidently due to the liberation of acetylene from the carbide present in the calcium cyanamide by the action of moisture. It has been ordered that in future calcium cyanamide must always be packed in iron drums for transportation. The author has found that if jute sacks which have been impregnated with rosin solution be used and filled whilst still damp, the rosin solution combines with the calcium cyanamide with which it comes in contact and forms a perfectly watertight coating.—A. S.

Copper carbonates; Basic ——. V. Auger. Comptes rend., 1914, **158**, 944—946.

In presence of carbon dioxide at pressures exceeding 3—4 atmospheres, amorphous basic copper carbonate, $8CuO.5CO_2.7H_2O$, is slowly converted into azurite, $Cu_3(CO_3)_2(OH)_2$. A mixture of equal parts of azurite and freshly prepared basic carbonate (in the form of a paste in the liquid from which it has been precipitated) is completely converted into azurite without the aid of carbon dioxide under pressure. Azurite is readily obtained by adding a soluble copper salt, in small portions, to a suspension of azurite in a solution of sodium carbonate and bicarbonate: the precipitated basic carbonate is allowed to change into azurite before addition of further portions of copper salt, and the liquid is kept distinctly alkaline. The interaction of malachite and carbon dioxide to form azurite and water, appears to be reversible: a mixture of azurite and malachite rapidly absorbs carbon dioxide in presence of water.—L. E.

Silver nitrate; Preparation and testing of —— for use in the silver voltameter. E. B. Rosa, G. W. Vinal, and A. S. McDaniel. Bull. Bureau of Standards, 1913, **9**, 524—551.

The most injurious impurities of silver nitrate to be used in a standard voltameter are reducing substances (especially colloidal silver) and uncombined acid or base. For determining the latter, 10 c.c. of the silver nitrate solution are treated with just sufficient of a 10 per cent. solution of pure potassium chloride in "conductivity" water to precipitate the silver, the silver chloride filtered off on asbestos or finely-divided platinum, and the solution titrated with N/1000 acid or alkali, using an ethereal solution of iodeosin as indicator. Control determinations must always be made. For use in the voltameter silver nitrate should be neutral or very slightly acid (0·0005—0·005 per cent.). For determining colloidal silver and other reducing impurities, 10 c.c. of a 66·6 per cent. solution of the silver nitrate are acidified with 1 c.c. of concentrated nitric acid (free from reducing impurities), and N/1000 permanganate is added, 0·5 c.c. at a time, until the pink colour persists undiminished in intensity for 5 mins. or longer. The permanganate test should be applied to the silver nitrate before and after fusion of the latter: organic impurities are partially oxidised during the fusion, with production of colloidal silver, which reacts very readily with the permanganate. Silver nitrate recrystallised from neutral water is slightly basic. The best method of purification is to recrystallise from strongly acid solution, until 10 c.c. of a 66·6 per cent. solution reduces not more than 1 c.c. of N/1000 permanganate, and then eliminate the nitric acid by fusion. When recrystallising, higher yields are obtained by dissolving in water and then adding the acid to the partially cooled solution. Fusion is effected at 250°—300° C., the nitrate being removed from the furnace as soon as melted.—A. S.

Samarium; Double sulphates of —— with sodium and ammonium. D. B. Keyes and C. James. J. Amer. Chem. Soc., 1914, **36**, 634—638.

An investigation of mixtures of samarium sulphate, sodium sulphate, and water, at 25° C., showed that only one double salt exists at this temperature, probably $2Sa_2(SO_4)_3,3Na_2SO_4,6H_2O$, whilst with ammonium sulphate the existence of the salt, $Sa_2(SO_4)_3,(NH_4)_2SO_4,7H_2O$ was indicated. Both salts were prepared.—F. Sodn.

Yttrium from yttrium earths; Separation of ——. H. C. Holden and C. James. J. Amer. Chem. Soc., 1914, **36**, 638—646.

A comparison of various methods of fractional precipitation showed that yttrium is most efficiently separated from solutions of rare earth metals in the form of chromate or phosphate.—F. Sodn.

Radioactive products; Action of colloids on —— in solution. T. Godlewski. Phil. Mag, 1914, **27**, 618—632.

It was shown previously (Le Radium, 1913, 250) that on passing an electric current through a solution of radium emanation together with its successive disintegration products, the radioactive substances were deposited almost exclusively at the cathode when the medium was acid or in presence of polyvalent cations and at the anode when the medium was alkaline or in presence of polyvalent anions. This suggests that the radioactive products are present as colloidal hydrosols and that the process is one of electrophoresis rather than electrolysis. Further experiments in which various colloids were added to the solution confirmed this view, and it was found possible to concentrate powerful radioactivity on a few mgrms. of a coagulated hydrosol (*e.g* colloidal gold or platinum coagulated by aluminium sulphate). Positive colloids can be precipitated merely by filtering through paper or glass-wool and in this way radium B and some radium C can be separated from water saturated with radium emanation, the greater part of the β-activity from dilute solutions of uranium nitrate (up to 10 grms. per litre), and some of the disintegration products of thorium and actinium. If a small quantity of aluminium sulphate be added to water containing radium emanation, the negative hydrosols become inversely charged, and all the products (RaA, RaB and RaC) are then retained by a paper filter. —A. S.

Patents.

Nitric acid; Process for concentrating ——. E. Collett, Christiania. Eng. Pat. 7597, Mar. 31, 1913. Under Int. Conv., April 3, 1912.

Nitric acid is concentrated in an evaporator, and the vapours are passed over a water-absorbing agent, such as sulphuric acid, in a drying apparatus; at one or more points, between the point of connection of the evaporator and dryer, and the point where the concentrated vapour escapes, regulated quantities of cooled sulphuric or nitric acid are introduced.—O. R.

Nitric acid; Process for concentrating ——. E. Collett, Christiania. Eng. Pat. 22,746, Oct. 8, 1913. Under Int. Conv., Oct. 30, 1912.

Dilute nitric acid is concentrated gradually by means of a number of communicating evaporating vessels, the escaping vapours, containing nitric acid, being introduced into a dephlegmation apparatus at suitable points one above the other. Nitric acid, preferably of 15 to 20 per cent strength, is continuously run in at the top of the dephlegmating column, and the acid to be concentrated may be introduced at a point slightly below the entry of the additional acid.—O. R.

Sulphuric acid [by the chamber method]; Apparatus fo producing ——. The British Thomson-Houston Co. Ltd., London. From General Electric Co., Schenectady N.Y., U.S.A. Eng. Pat. 15,293, July 2, 1913.

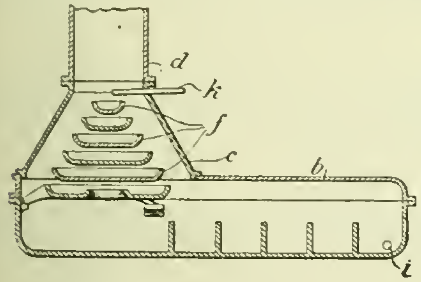
Proper movement of the gases through the system i secured by means of a centrifugal blower which acts b induction on the column of gases flowing from the last chamber, the speed of the blower being controlled by a device responsive to variations in the volume of gas passing out of the chamber. For example, the blower is arranged to supply air to an injector nozzle which projects into the stack connected with the exit pipe from the chambers, and the speed of the motor driving the blower is regulated by a float riding upon the column of gases in the exit pipe. —F. Sodn.

Sulphuric acid; Manufacture of —— and apparatus therefor. J. Mackenzie, Middlesbrough. Eng. Pat. 19,084, Aug. 22, 1913.

A series of tunnels is used instead of the usual arrangement of Glover tower, lead chambers, and Gay-Lussac towers. The sides, upper parts, and connections of the tunnels are made of acid-resisting and heat-proof bricks, which are set in lead saucers and lined with acid-resisting metal. At suitable intervals throughout the whole series of tunnels are special spraying nozzles through which acid is forced by centrifugal pumps.—O. R.

Sulphuric acid; Concentration of —— in cast-iron apparatus. Galizische Karpathen - Petroleum - A.-G. vorm. Bergheim u. MacGarvey and A. Gellen. Ger. Pat. 271,625, June 13, 1912.

The concentrating vessel, *b*, is heated by direct fire, and the combustion gases are led around the outside of the hood, *c*, in order to prevent condensation of weak acid in this part of the apparatus. The weak acid is introduced through *k*, and flows down over the series of dishes, *f*, or over a cascade, heated by the vapours from *b*. The concentrated acid is run off at *i*, and the acid vapours escaping through *d* are led to a condenser or the like.—A. S.



Catalytic agents [for the manufacture of ammonia, etc.]; Preparation of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Germany. Eng. Pat. 12,977, June 4, 1913.

Asbestos, meerschaum, etc., are soaked in a solution of alkali osmate, or alkali ruthenate, and dried. The contact mass thus obtained can be employed for catalytic purposes either directly, or after being heated, or acted upon with acid or reducing agents.—T. St.

Pyroligneous acid; Process for distilling crude ——. M. Klar, Marquette, Mich. U.S. Pat. 1,089,417, March 10, 1914.

The crude acid is preheated to a relatively high temperature, the tar and precipitated impurities removed, and the acid then passed continuously through a series of stills, working under progressively reduced pressures and temperatures, each still being heated by the vapours escaping from the preceding still.—O. R.

Ammonium sulphate; Process for the production of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 463,487, Oct. 9, 1913. Under Int. Conv., Dec. 9, 1912 and March 4, 1913.

A concentrated, slightly ammoniacal solution of ammonium sulphite is treated at about 80° C. with air under a pressure of 20 atmospheres or more, in the presence of a catalyst, such as *e.g.* porous earthenware impregnated with manganese hydroxide.—O. R.

Nitrogen; Process for the fixation of —— by means of ferro-aluminium or other ferro-compounds. Soc. Générale des Nitrures, Paris. Eng. Pat. 28,071, Dec. 5, 1913. Under Int. Conv., Nov. 20, 1913.

Ferro-aluminium (45 per cent. Al), to which have been added alumina and carbon, is heated to about 1200° C. and treated with nitrogen. The reaction between ferro-aluminium and nitrogen is sufficiently exothermic to raise the whole mass to a temperature high enough (about 1850° C.) to convert all the aluminium into nitride. In the place of ferro-aluminium, an alloy of iron and any element capable of fixing nitrogen, such as boron, silicon, etc., with the corresponding oxide and carbon may be employed.—O. R.

Nitrogen simultaneously with oxides of nitrogen; Process of obtaining ——. Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst a/Main, Germany. Eng. Pat. 28,737, Dec. 12, 1913. Under Int. Conv., Dec. 12, 1912. Addition to Eng. Pat. 3662 of 1913, dated Feb. 19, 1912 (this J., 1913, 1011).

The process described in the original patent is modified by introducing an indifferent gas, such as nitrogen, into the mixture of ammonia and air entering into reaction, whilst maintaining the requisite proportions of ammonia and air necessary for combustion.—O. R.

Baking salt. A. E. Berry, London, and A. Schaumlöffel, Stratford, Essex. Eng. Pat. 17,941, Aug. 6, 1913.

A mixture of sodium chloride, acid phosphate, and free phosphoric acid, prepared by incorporating common salt with purified phosphoric acid (preferably 16 per cent.) and drying the product.—F. Sodn.

Salt; Apparatus for making ——. C. L. Weil, Assignor to Diamond Crystal Salt Co., St. Clair, Mich. U.S. Pat. 1,091,721, March 31, 1914.

A brine preheater is combined with a series of successive heaters, to which heated brine may be supplied under pressure, and a succession of devices for producing self-evaporation of the heated brine. Means are provided for removing deposited salt and for leading the vapours produced during evaporation to the preheaters.—F. Sodn.

Sodium and potassium salts; Process of recovering —— from mixtures thereof. C. E. Dolbear, Assignor to E. H. Merrill, Berkeley, Cal. U.S. Pats. 1,088,216 and 1,088,333, Feb. 24, 1914.

(1). A solution containing sodium carbonate, sodium biborate, potassium chloride, sodium sulphate, and sodium chloride, is evaporated above 33° C. to separate sodium chloride and sulphate, cooled to not below 18° C. to separate sodium carbonate, sodium biborate, and potassium chloride, and then mixed with a fresh quantity of the original solution and the two processes repeated. The mixture of deposited sodium carbonate, sodium biborate, and potassium chloride is redissolved in water and treated with carbon dioxide to precipitate sodium bicarbonate, and the residual solution is treated with a "more or less soluble compound of an alkaline-earth metal" to precipitate the corresponding biborate, the remaining solution being evaporated to recover potassium chloride. (2). The steps of the preceding process are performed in the following order: (*a*), treatment with carbon dioxide; (*b*), treatment with alkaline-earth compound; and (*c*), evaporation above 33° C. and 18° C. respectively. In the absence of sodium carbonate and sodium chloride, treatment with carbon dioxide may be omitted.—O. R.

Sodium and potassium salts; Process of separating ——. Process of obtaining potash from felspar. H. P. Bassett, Assignor to The Spar Chemical Co., Baltimore, Md. U.S. Pats. 1,091,033 and 1,091,034, March 24, 1914.

(1). Sodium chloride is added to a substantially saturated solution of sodium and potassium sulphates, the mixture is heated to 60°—107° C., the sodium salts which crystallise out are withdrawn and introduced into a saturated solution of sodium sulphate, and crystals of the latter are recovered from the last-named solution at 60°—107° C. (2). Felspar, 40 parts, sodium bisulphate, 40 parts, sodium chloride, 14·4 parts, and carbon, 1—3 parts, are heated to a bright red heat for 1—2 hours, and the resulting mixture of sodium and potassium sulphates is separated from the insoluble portion of the fused mass, the two soluble constituents of the mixture being then separated from one another as above.—O. R.

Sodium hypochlorite; Apparatus for the manufacture of ——. A. Champ. First Addition, dated Oct. 9, 1913, to Fr. Pat. 454,751, Feb. 24, 1913 (this J., 1913, 910).

The use of the apparatus described in the principal patent is extended to the separation of any two substances of different densities.—O. R.

Crystallisation of hot-saturated saline solutions, especially solutions of potassium salts; Apparatus for the ——. G. Sauerbrey Maschinenfabrik A.-G. Ger. Pat. 271,246, Dec. 9, 1911. Addition to Ger. Pat. 257,685.

An improved form of the apparatus described in the chief patent (this J., 1913, 487), the plates on which the crystals are deposited being horizontal or nearly so, and enclosed in a casing through which a current of cooled air is forced by a fan. Various mechanical means of tilting the plates in order to discharge the deposited crystals are also claimed.—A. S.

Alunite; Method of calcining, and apparatus for treating ——. H. F. Chappell, New York. U.S. Pats. 1,089,109 and 1,089,110, March 3, 1914.

(1). The lower part of an upright column of alunite is heated externally by furnace gases to 900°—1000° C., and the gases are then admitted into the upper part of the column, whereby preliminary calcination takes place at about 600° C. The gases evolved from the lower portion of the column are withdrawn for the recovery of sulphuric acid. (2). An upright retort or muffle is surrounded by a heating chamber and surmounted by a supply shaft, down which the material descends into the muffle, the heating chamber communicating with the shaft, so that the latter is traversed by the furnace gases from the former; conduits are provided for withdrawing the gases from the muffle, and the furnace gases are prevented from being drawn into the muffle by means of a pipe admitting compressed air or steam at a point above the exit for the muffle gases.—O. R.

Magnesium chloride: Process for the production of ——. J. C. Graves and A. E. Schaefer, Saginaw West Side, Mich. U.S. Pat. 1,090,125, March 10, 1914.

A solution of calcium and magnesium chlorides is evaporated and subjected to fractional crystallisation; each step in the crystallising process is arrested before the solution has been cooled to the critical temperature, below which calcium chloride crystallises more readily than magnesium chloride.—O. R.

Core compound. H. K. Moore, Berlin, N.H. U.S. Pat. 1,091,690, March 31, 1914.

A homogeneous mixture of a soluble silicate (*e.g.*, sodium silicate) and neutralised waste acid liquor from the manufacture of sulphite fibre. The silicate is mixed with the neutralised liquor after evaporating at a low temperature, preferably *in vacuo* at about 90° F. (32° C.).—F. Sodn.

Fluorspar; Process of purifying ——. E. Bidtel, Golconda, Ill., Assignor to M. Eyssell, St. Louis, Mo. U.S. Pat. 1,091,795, March 31, 1914.

Fluorspar is treated with a solution of caustic alkali (preferably under pressure and with agitation), and the soluble products and slime resulting from the decomposition of the associated gangue (silica and silicates) are removed by washing.—F. Sodn.

Perborate preparations; Manufacture of easily soluble, stable ——. Ver. Fabriken für Laboratoriumsbedarf Ges. m. b. H. Ger. Pat. 271,194, May 17, 1911. Addition to Ger. Pat. 261,633.

Instead of adding to the perborates neutral salts of organic acids capable of forming complex salts with borates, as described in the chief patent (this J., 1913, 827), the corresponding acid salts, or solutions of the same may be used, but only in sufficient quantity to saturate not more than one-half of the base of the perborate. The mixtures obtained as described above or in the chief patent may be moistened with water or dilute alcohol and partially or completely dehydrated by drying or by fusing, with continuous stirring, at the temperature of the water-bath.—A. S.

Persulphates; [Electrolytic] Preparation of —— from sulphates or bisulphates, without the use of a diaphragm. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 271,642, April 18, 1913.

Cathodes of tin or aluminium are used.—A. S.

Zinc sulphate from [silicious] zinc ores; Process of preparation of ——. S. Araki. Fr. Pat. 464,038, Sept. 2, 1913.

The ground, calcined ore is decomposed with a 20 per cent. solution of sodium bisulphate, heavy metals are precipitated by zinc foil or dust, then the greater part of the iron and manganese by caustic alkali and an oxidising agent, such as air or calcium hypochlorite, and the remainder by boiling with hydrated silicic acid, formed by the addition of alkali silicate and sulphuric acid. After filtering, excess of alkali silicate is neutralised with an acid, the solution is boiled to render colloidal silica insoluble, and filtered.—O. R.

Zinc oxide; Process for obtaining pure —— from crude oxides containing lead oxide. H. Heimann. Ger. Pat. 271,136, Nov. 14, 1912.

The lead oxide is extracted from the crude oxide by a solution of caustic potash, and the solution is electrolysed with insoluble electrodes, whereby spongy lead is deposited at the cathode and an insoluble lead compound (probably $3PbO+2PbO_2+3H_2O$) at the anode, leaving nearly pure caustic potash solution for use again.—A. S.

Metallic oxides and hydroxides; Process for obtaining practically pure ——. F. Cochlovius. Fr. Pat. 464,016, Aug. 22, 1913. Under Int. Conv., May 13, 1913.

Solutions of salts, *e.g.*, of copper, zinc, etc., are treated with the equivalent quantity of quicklime, the solution filtered, and the precipitate heated to about 500° C. to decompose oxychlorides, and washed with water.—O. R.

Phosphorus pentoxide; Process of hydrating ——. S. Peacock, Chicago, Ill., Assignor to International Agricultural Corporation, New York. U.S. Pat. 1,089,784, Mar. 10, 1914.

Phosphorus pentoxide is treated with water at 90° C. until a solution of 1·2° B. (sp. gr. 1·009) is formed, the temperature being then raised to above 100° C., but below the boiling point of the solution.—O. R.

Sulphur [from pyrites, etc.]; Commercial preparation of ——. W. A. Hall, New York. Eng. Pat. 29,365, Dec. 20, 1912.

Part of the sulphur is distilled by the application of a direct reducing flame, and the rest is removed as sulphur dioxide by roasting, the sulphur dioxide being subsequently converted into hydrogen sulphide (preferably by passing it through the producer employed in generating the gas required for the reducing flame), which is burned in the reducing flame, so that the contained sulphur is liberated in the free state and mixes with that passing off by distillation. The distilling and roasting operations are preferably conducted in two superposed furnaces. The process is a modification of that described in Eng. Pats. 20,758 and 26,595 of 1912 (this J., 1914, 77, 135). —F. Sodn.

Sulphur; Production of —— from pyrites and other metallic sulphides. W. A. Hall, New York. Eng. Pat. 8279, April 8, 1913.

Metallic sulphides are heated directly by a reducing flame, produced by the combustion of a gas rich in hydrogen with sufficient air to give the best combustion possible without the flame losing its reducing character. The sulphur vapour formed is forced to the top of the furnace and is discharged at a level above that at which the air is admitted.—T. St.

Sulphur dioxide; Method of producing ——. H. K. Moore and R. B. Wolf, Berlin, N.H. U.S. Pat. 1,091,689, March 31, 1914.

Combustion products containing sulphur dioxide are passed through a solution of calcium chloride or other solvent, cooled to about 32° F. (0° C.), and the sulphur dioxide is subsequently extracted from the refrigerated solution and liquefied, *in vacuo*. The solvent is preferably circulated continuously from an absorbing chamber to a vacuum chamber, and *vice versa*.—F. Sodn.

Hydrogen or hydrogen-containing gas mixtures: Process of bringing —— to reaction and apparatus therefor. M. Pier, Zehlendorf, Germany. U.S. Pat. 1,090,874, Mar. 24, 1914.

The gaseous mixture containing hydrogen is subjected to pressure in an inner, non-metallic vessel, which is proof against chemical action and leakage of hydrogen, and is contained inside an outer metallic vessel. The outer vessel is heated, and the space between the two is maintained under a pressure different from that of the inner vessel. this difference of pressure in the two vessels being utilised to equalise the pressures in both.—O. R.

Density regulator for use in the manufacture of sulphuric acid and other purposes. L. Santa, Turin, Italy. Eng. Pat. 18,615, Aug. 15, 1913.

See Fr. Pat. 461,641 of 1913; this J., 1914, 199.—T. F. B.

Nitric acid or nitric acid monohydrate; Impts. in, and apparatus for, the distillation of ——. Verein Chem. Fabriken in Mannheim, Mannheim, Germany. Eng. Pat. 20,189, Sept. 6, 1913. Under Int. Conv., Sept. 16, 1912.

See Fr. Pat. 462,290 of 1913; this J., 1914, 311.—T. F. B.

Nitric acid; Process for concentrating dilute ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Fr. Pat. 463,859, Oct. 21, 1913. Under Int. Conv., Oct. 30, 1912.

See Eng. Pat. 22,746 of 1913; preceding.—T. F. B.

Nitric acid; Process for the continuous manufacture of ——. Saccharin-Fabrik A.-G. vorm. Fahlberg, List und Co. Fr. Pat. 464,561, Sept. 30, 1913. Under Int. Conv., Sept. 30, 1912.

See Eng. Pat. 3264 of 1913; this J., 1913, 909.—T. F. B.

Sulphate furnaces; Rakes or scrapers for stirring apparatus in ——. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 16,999, July 24, 1913. Under Int. Conv., Feb. 14, 1913.

See Fr. Pat. 460,484 of 1913; this J., 1914, 23.—T. F. B.

Sodium bisulphate in a directly calcinable form; Process for the manufacture of ——. Akt.-Ges. Dynamit Nobel, Vienna. Eng. Pat. 24,604, Oct. 29, 1913. Under Int. Conv., Jan. 22, 1913.

See Ger. Pat. 263,120 of 1913; this J., 1913, 909.—T. F. B.

Oxides or hydroxides; Process for the manufacture of metal ——. F. Cochlovius, Frankfort, Germany. Eng. Pat. 19,340, Aug. 26, 1913. Under Int. Conv., May 13, 1913.

See Fr. Pat. 464,016 of 1913; preceding.—T. F. B.

Ammonium sulphate; Producing ——. A. Mittasch and H. Morawitz, Assignors to Badische Anilin und Soda Fabrik, Ludwigshaten on Rhine, Germany. U.S. Pat. 1,091,234, March 24, 1914.

See Fr. Pat. 463,487 of 1913; preceding.—T. F. B.

Ammonia; Process for preparing ——. R. W. Wallace and E. Wassmer. Fr. Pat. 464,692, Nov. 10, 1913.

See Eng. Pat. 18,450 of 1912; this J., 1914, 22.—T. F. B.

Nitrous vapours; Process and apparatus for absorbing —— in the dry and with heat by the aid of a base such as lime. A. T. Schloesing, Paris, Assignor to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pat. 1,092,295, April 7, 1914.

See Fr. Pat. 441,607 of 1911; this J., 1912, 922.—T. F. B.

Alkali chlorides; Treatment of —— to obtain useful products. J. A. Kendall. Fr. Pat. 465,229, Nov. 22, 1913. Under Int. Conv., Nov. 22, 1912.

See Eng. Pat. 26,896 of 1912; this J., 1914, 22.—T. F. B.

Gases [oxygen] from solid substances; Apparatus for extracting ——. C. Weston. Fr. Pat. 464,446, Nov. 5, 1913. Under Int. Conv., Nov. 5, 1912.

See Eng. Pat. 25,326 of 1912; this J., 1914, 24.—T. F. B.

Purification of gases [from suspended particles] by formation of mist by supersaturation. Ger. Pat. 270,757. *See* I.

Conversion of animal substances [waste leather] into ammonia and combustible gases. Eng. Pat. 5348. *See* IIA.

Production of alloys of alkali metals by electrolysis of fused alkali hydroxides, and production from these alloys of alkali metals or their compounds. Fr. Pat. 464,951. *See* X.

VIII.—GLASS; CERAMICS.

Tiles; Splitting of —— by frost. C. Rad. Tonind.-Zeit., 1914, 38, 649.

Glazed tiles with strongly porous edges are split by frost, whereas unglazed tiles made of the same clay are not affected Glazed bricks are more resistant than glazed tiles. The difference is attributed to the greater thickness and less exposed situation of the bricks, owing to which not so much water is absorbed, whereas thin, flat, roofing-tiles become fully saturated.—O. R.

Patents.

Melting glass or other fusible substances ; Furnace for —— and method of working it. Higham Manufacturing Co., Ltd. Fr. Pat. 464,993, Nov. 17, 1913. Under Int. Conv., Nov. 18, 1912.

See Eng. Pat. 26,494 of 1912 ; this J., 1914, 354.—T. F. B.

Kilns for making tiles, pottery, and similar articles. C. Dressler. First Addition, dated Oct. 16, 1913, to Fr. Pat. 432,427, July 21, 1911. Under Int. Conv., Oct. 18, 1912.

See Eng. Pat. 23,863 of 1912 ; this J., 1913, 1094.—T. F. B.

Glazes ; Process for making white or coloured, opaque ——. O. Völkel. Fr. Pat. 464,417, Nov. 4, 1913.

See Ger. Pat. 267,191 of 1912 ; this J., 1914, 137.—T. F. B.

IX.—BUILDING MATERIALS.

Concrete ; Electrolysis in ——. E. B. Rosa, B. McCollum, and O. S. Peters. Technol. Papers of the Bureau of Standards, Washington, 1913, No. 18, 137 pp.

Cracking of reinforced concrete is brought about by electric currents owing to oxidation of the iron (acting as anode) with the formation of oxides, having 2·2 times the volume of the original iron. Non-corrodible metals do not cause cracking. Corrosion of iron anodes, even in wet concrete, is very slight below 45° C., owing to the inhibiting effect of slaked lime and other alkalis, the passivity of iron in concrete being chiefly due to the calcium hydroxide present. The addition of a small amount of salt (to prevent freezing whilst setting) greatly accelerates corrosion and tendency to crack, reinforced concrete structures which are in contact with salt water, being consequently the most susceptible to electrolytic troubles. A distinct softening of the concrete occurs near the cathode, completely destroying the bond between the reinforcing material and the concrete. Whilst the anode effect becomes considerable only with comparatively high voltages, the cathode effect develops at all voltages at a rate approximately proportional to the voltage, but becomes serious only where the concrete is wet and the potential difference rather high. The softening is due to the gradual concentration of sodium and potassium ions near the cathode, until the free alkali attacks the cement. Non-reinforced concrete structures are immune from troubles caused by electrolysis.—O. R.

Patents.

Iron or steel or like structures ; Composition for covering ——. N. J. Porter, Belfast. Eng. Pat. 14,182, June 19, 1913.

The iron or steel surface is coated successively with a bituminous paint, and one or more coats of mineral rock asphaltum applied in a plastic state. It is then roughened, or gritty material applied, to form a bond for a magnesite and magnesium chloride, or similar composition, which is laid on in a plastic condition. The combined covering adheres to the steel without the use of holdfasts or cleats. —T. St.

Heat-insulating material ; Process of producing ——. J. A. Scharwath, Cranford, N.J. U.S. Pat. 1,092,402, April 7, 1914.

A mass consisting essentially of alkaline silicates is heated in an open mould, and is agitated and the solid crust removed, until a porous solid product is obtained.—A. T. L.

Cement-manufacturing apparatus. F. Worm, Assignor to German-American Portland Cement Works, La Salle, Ill. U.S. Pat. 1,092,551, April 7, 1914.

Between the feed-end of the kiln and the stack is a dust-collecting chamber of greater cross-section than the kiln and stack, and increasing in cross-section towards the stack. The chamber communicates with the stack through a passage of reduced cross-section, which has an inclined lower wall rising from a dust-collecting pocket in the foot of the chamber. Air is admitted to the stack at a point opposite the passage from the dust-chamber. —A. T. L.

Bricks, artificial stone, and similar products ; Manufacture of ——. L. F. Kaye, New York, and British Silicate Engineering Co., Ltd., London. Eng. Pat. 10,288, May 1, 1913.

See Fr. Pat. 457,664 of 1913 ; this J., 1913, 1012.—T. F. B.

Plaster ; Process for making ——. W. M. Brothers. Fr. Pat. 465,146, Nov. 20, 1913. Under Int. Conv., Jan. 9, 1913.

See Eng. Pat. 639 of 1913 ; this J., 1913, 604.—T. F. B.

X.—METALS ; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Titaniferous iron ores ; Smelting of —— in the blast furnace. O. Simmersbach. Stahl u. Eisen, 1914, **34**, 672—674.

In smelting titaniferous iron ores the aim should be to obtain all the titanium in the slag, as it does not improve the quality of pig-iron. Ores mixed so that the slag does not contain more than 2 per cent. Ti, can be smelted in the same way as titanium-free ores ; and provided that the slag contains under 6 per cent. MgO, its melting point will not be inconveniently high. Examples of titaniferous iron ores smelted in America are given, with analyses of the ores, slags, etc.—T. St.

Iron ; Embrittling of —— by caustic soda. J. H. Andrew. Trans. Faraday Soc., March, 1914. [Reprint, 14 pages.]

Wrought iron corrodes slowly, becomes highly crystalline and eventually brittle, by immersion in a concentrated aqueous solution of caustic soda at 100° C. for several months. The corrosion is attributed to electrolytic action between the two phases, crystalline and amorphous, of which the metal is constituted, iron going into solution at the anode (forming sodium ferrite), hydrogen being liberated at the cathode. Part of the hydrogen is occluded by the metal, being first absorbed by the amorphous constituent, thereby forcing the crystals apart, and ultimately causing the iron to become crystalline and brittle. The brittleness decreases with time, an equilibrium being finally established between the metal and the gas, and is due rather to molecular rearrangement induced by occlusion or evolution of hydrogen than to the mere presence of the latter in solution. The potential difference between the amorphous and crystalline phases and hence the rate of corrosion decrease as the latter phase becomes hydrogenised, the passivity of iron produced by immersion in caustic soda being due to this cause. Similar results were obtained with electrodeposited iron, but steel containing 0·5 per cent. C was much less affected by caustic soda solution. The recrystallisation of electrodeposited iron upon cooling through the Ar_3 point is also considered to be due to evolution of hydrogen.—W. E. F. P.

Iron nitride. G. Charpy and S. Bonnerot. Comptes rend., 1914, **158**, 994—996.

Iron nitride (Fe_2N), obtained by heating finely-divided iron in a rapid current of ammonia at 650°—700° C., is completely decomposed when heated in nitrogen above 600° C., even at pressures as high as 18 atmospheres. Below 600° C. only about half the nitrogen is expelled, which suggests the existence of a more stable nitride Fe_4N. Iron does not combine directly with nitrogen even at pressures of 18 atmospheres. Having regard to its properties, iron nitride probably does not exist in metallurgical products; the nitrogen often found in iron may be either occluded or combined with some element other than iron.—W. H. P.

Iron in soils; Electrolytic corrosion of ——. B. McCollum and K. H. Logan. Technol. Papers of the Bureau of Standards, Washington, 1913, No. 25, 69 pp.

Two kinds of corrosion are distinguished, (1) electrolytic corrosion due to external electric currents, and (2) self-corrosion due to currents originating, from whatever cause, within the corroding system itself. The "efficiency of corrosion" (*i.e.* ratio of actual corrosion to that theoretically possible for a given current) is greater the lower the current density, is practically independent of the voltage, and increases with the moisture content, up to saturation, of the soil. Corrosion of iron embedded in earth is always greater in open vessels than in sealed vessels. There is no material difference in the "efficiency of corrosion" of various kinds of iron used for underground pipes. The electrical resistance of the soil varies greatly with the temperature, being over 200 times greater at −18° C. than at +18° C.—O. R.

Steels; Equilibrium of carburisation of —— *in fused mixtures of chloride and cyanide of potassium.* A. Portevin. Comptes rend., 1914, **158**, 1025—1027.

Steel (C 0·78 per cent.) and pure iron were immersed in molten mixtures of potassium chloride and cyanide containing 25, 50 and 75 per cent. KCN, respectively, for periods varying from 9 mins. to 5 hrs. at 900° C. The depth of decarburisation of the steel (maximum 0·75 mm.) and of carburisation of the iron (maximum 0·62 mm.) were measured and the percentage of carbon in the surface layer determined in each case. The mean results in the 5 hour tests were 0·25 per cent. C for the decarburised and 0·26 C for the carburised layers, the two phenomena apparently tending towards a common limit irrespective of the proportion of cyanide in the bath.—W. E. F. P.

Nickel-steel; Influence of gases on rich ——. W. Froehlich. Stahl u. Eisen, 1914, **34**, 723—724.

The gases, especially hydrogen, present in rich nickel-steel could not be completely removed—even by fusion in a 6-mm. vacuum. Metal treated in this manner absorbed hydrogen when subsequently ignited in a current of the gas; chilling slightly increased the hydrogen content of the metal. Mechanical tests showed that rich nickel-steel, unlike steel and iron, was not adversely affected by contact with gases during the manufacturing process.—W. R. S.

Cobalt in steel; Determination of ——. P. Slawik. Chem.-Zeit., 1914, **38**, 514—515.

1—2 grms. of drillings are dissolved in dilute hydrochloric acid, oxidised with potassium chlorate and the excess of acid evaporated. The solution is treated with zinc oxide emulsion, added in small portions at a time, carefully avoiding excess, until the precipitate coagulates. The volume is made up to 500 c.c., and 250 c.c. are filtered. The solution, containing only cobalt, nickel and manganese, is concentrated to 100 c.c., treated with 20 c.c. of strong hydrochloric acid, and the cobalt precipitated by 30 c.c. of a 2 per cent. alcoholic solution of nitroso-β-naphthol. The precipitate is strongly ignited and weighed as Co_3O_4. In the case of nickel steel the ignited precipitate should be dissolved and the precipitation repeated.—W. R. S.

Gold and platinum metals; Method of assaying concentrates and battery chips for ——. A. F. Crosse. J. Chem., Met., and Min. Soc., S. Africa, 1914, **14**, 373—374.

The lead button obtained in the ordinary pot assay is cupelled at a fairly high temperature, 2—4 grms. of (standard) silver added, and the resulting bead alloyed with about 3 times its weight of cadmium, the latter being fused under potassium cyanide in a porcelain crucible at a low red heat, the silver bead added, and the charge shaken to produce a homogeneous alloy. From the cooled melt the cyanide is removed by warm water, and the alloy digested with dilute nitric acid (1 : 3). The insoluble portion is collected on a filter, the paper incinerated at a low temperature, and the residue fused at a dull red heat with potassium bisulphate. The cooled melt is dissolved in warm water, filtered (the filtrate may contain rhodium and palladium), the filter paper gently incinerated and the residue digested with cold *aqua regia*; the insoluble osmiridium being filtered off, ignited and weighed. The *aqua regia* solution, containing gold and platinum, is twice evaporated to dryness on the water-bath (a few drops of hydrochloric acid being added each time) and the final residue dissolved in a little water: gold is precipitated from the solution by a slow current of sulphur dioxide, and then platinum by means of magnesium. Synthetical tests with gold and platinum gave satisfactory results.—W. E. F. P.

Mineral production of the United Kingdom in 1913. Board Board of Trade J., April 23, 1914. [T.R.]

The following tables, showing the output of coal and certain other minerals in the United Kingdom at mines worked under the Coal and Metalliferous Mines Act (the returns from quarries under the Quarries Act are not yet available) during the year 1913, with comparative figures for the preceding year, are extracted from an advance proof of tables prepared for the Mines and Quarries General Report and Statistics for 1913:—

I.—Output of minerals under the Coal Mines Acts.

	1912	1913.
	Tons.	Tons.
Barium (compounds)	4,712	4,610
Coal	260,398,578	287,411,369
Clay and shale, other than fire-clay and oil shale	399,033	457,244
Fire-clay	2,287,719	2,585,763
Igneous rocks	268	688
Iron pyrites	8,442	8,964
Ironstone	6,744,258	7,709,624
Limestone	12,009	7,525
Oil shale	3,184,826	3,280,143
Sandstone (including "Ganister")*	152,156	144,923

* The quantity of ganister obtained was 143,076 tons in 1912, and 141,349 tons in 1913.

II.—Output of certain minerals under the Metalliferous Mines Regulation Acts.

	1912.	1913.
	Tons.	Tons.
Arsenic	2,193	1,694
Barium (compounds)	38,055	43,408
Bauxite	5,790	6,055
Chert, flint, etc.	4,787	5,173
Clay and shale	123,279	133,984
Copper ore and copper precipitate	1,912	2,705
Fluorspar	28,691	33,833
Gypsum	243,811	238,494
Igneous rocks	61,117	57,921
Iron ore	1,675,868	1,881,853
Iron pyrites	2,080	2,463
Lead ore	25,383	24,265
Limestone *	343,560	356,316
Manganese ore	4,170	5,393
Ochre, umber, etc.	5,804	5,999
Rock salt	218,055	214,573
Sandstone	98,022	89,718
Slate	101,648	95,271
Tin ore, dressed †	6,822	6,942
Zinc ore	17,704	17,294

* Including 1,432 tons of calc spar in 1912 and 1,267 tons in 1913.

‡ In addition, 408 tons of undressed tin ore were obtained in 1912 and 1,042 tons in 1913.

The above figures do not in all cases represent the total production of the minerals for the year. Large quantities of several important minerals, such as iron ore, limestone, sandstone, slate, clay, etc. are obtained from quarries under the Quarries Act and from other open workings, the returns from which are not yet available. The totals for coal and for the ores of copper, lead, and zinc are, however, substantially complete.

Copper solutions; Action of iron sulphides on ——. S. Croasdale. Eng. and Min. J., 1914, **97**, 745—748.

METALLIC copper, not copper sulphide, is precipitated from solution by ferrous sulphide or iron matte:

$$4FeS + CuSO_4 = Cu + FeSO_4 + Fe_3S_4.$$

When the solution contains more than 3 per cent. of free (sulphuric) acid, the precipitated metal is masked by the presence of a small quantity of copper sulphide, but the amount of copper in the precipitate ($Cu + Fe_3S_4$) remains practically constant irrespective of the time of contact and the temperature of the solution. Artificial sulphides of iron and copper, containing more than 5 per cent. of the latter, have only a slight precipitating effect upon copper solutions. There is apparently no rule governing the action of the natural sulphides of iron, some of which, both simple and complex, precipitate copper rapidly from its solutions under favourable conditions, whereas others have practically no precipitating effect.—W. E. F. P

PATENTS.

Iron ore and the like; Process for briquetting ——. G. Crusius, Kreis Peine, Germany. Eng. Pat. 27,536, Nov. 29, 1913. Under Int. Conv., Nov. 30, 1912.

TAR from which the middle oils, water and light oils, have been removed, is used as a binding material for iron ore, Thomas slag, etc.—T. ST.

Iron ores, etc.; Treatment of fine —— by agglomeration in a rotary furnace and smelting in the blast furnace. G. Polysius. Ger. Pat. 271,367, March 2, 1912.

THE fine ore, with the necessary additions, is agglomerated in one or more rotary furnaces disposed above the blast-furnace into which the hot agglomerated material is charged directly.—A. S.

Iron and other metals; Process and apparatus for recovering —— from blast-furnace dust and the like. J. B. E. Billard. Fr. Pat. 464,623, Nov. 6, 1913.

A MIXTURE of the dust with bituminous coal and lime is agglomerated by "coking" and then smelted, the coking being effected in a series of parallel channels communicating with the smelting chamber and heated by the gases from the latter.—W. E. F. P.

Iron oxide ores; Process and rotary kiln for the preparation of —— for magnetic concentration. E. Schröder. Ger. Pat. 271,695, July 21, 1911.

THE ore is heated under reducing conditions by a flame from a burner, the latter being introduced, at the lower end of the rotary kiln, and so near to the wall of the kiln, that the ore comes in contact with the inner portion of the flame.—A. S.

Iron; Process of treating molten ——. J. E. Johnson, jun. Fr. Pat. 464,208, Oct. 29, 1913. Under Int. Conv., Aug. 13, 1913.

To improve resistance, fineness of grain and "whiteness" of the lower grades of cast iron, a portion of the molten metal is "blown" until practically all the silicon is oxidised, and then at a lower temperature (to prevent oxidation of carbon) until saturated with oxygen. Silicon and the remainder of the original metal are then added.
—W. E. F. P.

[Steel.] Refining metals; Process of ——. A. Patton, McKeesport, Pa. U.S. Pat. 1,091,588, March 31, 1914.

MOLTEN steel from a Bessemer or an acid open-hearth furnace is poured into an acid-lined vessel, and thence, without the acid slag, into a basic-lined receptacle in which it is treated, first with materials to form a basic slag and then with a recarburiser and manganese.—A. S.

Iron and nickel; Separation of —— from cupriferous sulphide ores and metallurgical products (mattes). W. Borchers and E. Thilges. Ger. Pat. 271,595, Aug. 1, 1913.

THE material is melted with lime or limestone and a carbonaceous reducing agent, the latter being introduced gradually, so that at first mainly iron, and then iron and nickel are separated, whilst, simultaneously, the basic slag becomes richer in sulphides (calcium sulphide), which retard the separation of the copper. The lining of the hearth may serve as source of carbonaceous reducing agent, the carbon dissolving in and diffusing through the iron or ferro-nickel first separated, and only then coming in contact with the charge above.—A. S.

Copper; The recovery of —— from its ores and solutions. H. L. Sulman, H. F. K. Picard, and Minerals Separation Limited, London. Eng. Pats. 1152, Jan. 15, 9171, April 18, and 16,017, July 11, 1913.

PYRITES or copper pyrites is heated with lime, or with lime and carbon, and the product, containing ferrous sulphide and calcium sulphide, is used to precipitate copper as sulphide from copper-bearing solutions, preferably acidified. The copper sulphide is added to ore pulp which is to be treated by the agitation-froth method of concentration, to increase the volume and coherence of the froth. Pulp containing copper in solution, may be treated directly with the sulphide precipitant.—T. ST.

Boron-copper; Manufacture of ——. E. D. Gleason, Brooklyn, N.Y., U.S.A. Eng. Pat. 8790, April 14, 1913.

A FUSED mixture of calcium fluoride, 3, and vitrified boric acid, 1 part, is heated until dense fumes of boron fluoride are evolved, and molten copper at about 2500° F. (1371° C.), or higher, is then added. Copper having boron in the graphitoidal state uniformly distributed throughout it is thus obtained, and is used for preparing alloys of copper and lead, and of copper, lead and tin, in which the copper is comminuted to the greatest possible extent, and uniformly distributed.—T. ST.

[Copper] Alloy. T. Westley, Dudley. Eng. Pat. 15,982 July 11, 1913.

DIFFERENT grades of the alloy have the following composition:—

	Cu	Sn	Zn	Pb	Mn	Al	P
	lb.	lb.	lb.	lb.	lb.	lb.	lb.

—W. E. F P.

Metal founding. The British Thomson-Houston Co., Ltd., London. From the General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 6286, March 13, 1913.

COPPER, silver, or other metal which absorbs gas when melted, is melted and superheated above a layer of a mixture of boric anhydride (2 or more parts per 100 parts of metal) and an inert material such as charcoal or coarse sand. Copper is preferably heated to about 1300° C. The boric anhydride, which remains melted below the metal, is then gradually stirred into the melt to effect purification, and when finally, with the inert material, it floats on the metal, the latter is cast as quickly as possible. Copper thus treated has a high electrical conductivity.
—T. ST.

Metalliferous ores; Concentrating apparatus for cleaning separating and classifying ——. G. H. Harris, Wadebridge, Cornwall. Eng. Pat. 7233, Mar. 26, 1913.

To shake or bump washing or jigging tables, a shaking mechanism of the type having a driven member (pulley crank or eccentric), attached to the upper end of the shaf about which the table rotates, adjustable out of balance
—W. E. F. P.

Sodium; Manufacture of —— and apparatus for use therewith. J. W. Swan, Warlingham, Surrey, and J. A. Kendall, London. Eng. Pat. 7987, April 4, 1913.

THE mixture of sodium vapour and carbon monoxide produced by distilling sodium carbonate and carbon, is passed through fused sodium cyanide to retain any carbon and sodium carbonate produced by a reversal of the original action. The cyanide may be introduced into the retort with the soda, or may be formed there by passing a current of nitrogen into the retort. The condenser is provided with suitable outlets for cyanide, sodium, and carbon monoxide.—T. ST.

Alkali metals; Process for preparing —— by reaction between their haloid salts and certain compounds of alkaline-earth metals. L. Hackspill and C. Staehling. Fr. Pat. 464,469, Nov. 5, 1913.

AN alkali halide is heated, preferably in a vacuum, with a carbide, hydride or silicide of an alkaline-earth metal. —W. E. F. P.

Alkali metals; Production of alloys of —— by electrolysis of fused alkali hydroxides, and the production from these alloys of alkali metals or their compounds. E. A. Ashcroft. Fr. Pat. 464,951, Nov. 14, 1913.

A THIN layer of melted caustic alkali is electrolysed at about 400° C., using a molten heavy metal as the cathode, and a current density as high as possible at the anode, the electrolyte and cathode being kept in movement. The alloy may be further treated in a second cell, working separately or in combination with the first and with or without the use of electrolysis, for the production of alkali metals, alkali amides, cyanamides, cyanides, etc.—B. N.

Galvanising wire, sheets and other products; Bath for ——. N. K. Turnbull, Manchester. Eng. Pat. 9815, Apr. 26, 1913.

THE molten zinc is floated upon molten lead, and contamination of the zinc by the steel container is prevented by confining the external heating of the latter to the bottom and lower portion of the sides, and by providing the upper, unheated portion with a lining of refractory material or solidified zinc, an external, annular cooling chamber being disposed around the top of the container in the latter case.—W. E. F. P.

Screw or worm conveyers for use in charging rotary reduction furnaces. A. E. Bourcoud, London. Eng. Pat. 10.207, Apr. 30, 1913.

THE distance between the discharge end of the conveyor and the end of its casing is lengthened, either by means of a telescopic fitting, or by altering the position of the worm or screw. A mass of material sufficient to prevent leakage of gas is thus maintained in the discharge end of the conveyor casing.—W. E. F. P.

Tin ores or concentrates; Treatment of ——. E. V. Pearce, Penzance. Eng. Pat. 11,612, July 22, 1913.

THE ore (cassiterite), alone or mixed with sulphur or pyrites, is heated out of contact with air. The sulphides or other compounds formed from metallic impurities are then removed by treatment with mineral acids, the hydrogen sulphide evolved being employed for the separation of commercial products from the acid solution. The residue from the acid treatment is smelted for tin as usual. —W. E. F. P.

Nickel; Recovery of —— from its ores. H. L. Sulman, H. F. K. Picard, and A. E. Roberts, London. Eng. Pats. 17,131, March 18, and 18,769, Aug. 18, 1913. Additions to Eng. Pat. 27,626, Nov. 30, 1912 (this J., 1914, 30).

MAGNESIUM silicate ores (garnierite) containing nickel are treated with a limited quantity of sulphuric acid, which has a selective action on the nickel. The latter is finally precipitated by a soluble sulphide. Magnesium sulphate is crystallised from the filtrate, mixed with two equivalents of common salt, and the mixture, after heating to drive off steam and hydrochloric acid, is roasted in a reverberatory furnace with coal to produce sodium sulphide, which is used for the precipitation of nickel in succeeding operations.—T. ST.

Metals; Process of treating ——. [Rendering iron and copper non-oxidisable.] E. G. Gilson, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,091,057, March 24, 1914.

METALS such as iron or copper are rendered non-oxidisable by heating them in a non-oxidising atmosphere to 600°—900° C. in contact with a powdered mixture of pure aluminium and aluminium oxide, and a small percentage of a chloride.—T. ST.

Aluminium alloy. W. A. McAdams, Bay Shore, N.Y. U.S. Pat. 1,092,500, April 7, 1914.

AN alloy of Al, 70; Zn, 26; Cu, 3, and Ag, 1 parts by weight. —T. ST.

Aluminium and its alloys; "Flux" for —— and process of making the same. J. C. Gelly. Fr. Pat. 464,505, Nov. 6, 1913. Under Int. Conv., Nov. 15, 1912.

THE material (deoxidant, etc.) is composed of Ni, 1; Mn, 1; Cr, 1 and "infusible aluminium" 9—12, parts by weight, and prepared by adding the last-named ingredient (obtained by reaction between anhydrous aluminium chloride and potassium) to the molten mixture of the other three, and finally pulverising the product.—W. E. F. P.

[Aluminium] Metals; Process for producing colourations and black tints upon ——. L'Aluminium Français. Fr. Pat. 464,722, Jan. 20, 1913.

A NEUTRAL or alkaline solution of ammonium molybdate is electrolysed in a cell of which the metal (aluminium) forms the cathode.—W. E. F. P.

Electric furnace for metallurgical purposes. H. H. Buckman, jun., Indianapolis, Ind. U.S. Pat. 1,092,764, April 7, 1914.

THE electrodes of the furnace extend downwards from a support capable of rotating horizontally. One electrode is near the axis of rotation, and is of different polarity from the others, which are equidistant from it.—T. ST.

Metals; Precipitation of —— from cyanide solutions. C. Butters, Oakland, Cal. U.S. Pat. 1,092,765, April 7, 1914.

CYANIDE solutions containing dissolved precious metals are passed through a rotating mill containing commercial aluminium as a lining and in the form of granular pieces. —T. ST.

Annealing furnace. H. Hillebrand, jun. Ger. Pat. 271,438, Nov. 19, 1912. Addition to Ger. Pat. 257,716 (this J., 1913, 540).

THE cooling chamber may be mounted, independently of the furnace, on a movable support, and between it and the furnace are two concentric annular sealing troughs, the inner one filled with granular material, such as sand, and the outer one with a heavy oil. Both the cooling chamber and the furnace are thus effectively sealed, and the inner sand seal serves to prevent the transference of heat to the oil seal and the entry of oil vapours into the furnace. —A. S.

Iron; Method of precipitating —— from solutions containing zinc and iron. A. Ramén, Helsingborg, Sweden. Eng. Pat. 9064, April 17, 1913.

SEE Ger. Pat. 266,349 of 1912; this J., 1913, 1156.—T. F. B.

Patents.

Accumulators ; Lead ——. G. C. Dymond, Liverpool. From Marquise des Ligneris née Tailhandier du Plaix. Paris Eng. Pat. 15,327, July 3, 1913.

A plate for lead accumulators comprises a thin body portion with horizontal strips inclined upwards at an angle to it, thus forming grooves for the reception of the active material. The strips may be arranged on both sides of the plate, either opposite to one another, or with the strips on one side opposite to the grooves on the other, and the body portion may be cut away to make the plate lighter, preferably leaving supporting bands. A well-ground mixture of litharge and glycerin is used as the paste. (Reference is directed to Eng. Pats. 11,923 of 1887, 8904 and 18,034 of 1895, 780 of 1896, 23,243 of 1898, 11,349 and 16,636 of 1899, 6454 and 10,191 of 1901, 4520 and 12,857 of 1902, and 24,224 of 1908 ; this J., 1888, 218 ; 1896, 277, 361 ; 1903, 216.)—B. N.

Electrodes applicable to primary and secondary batteries and to electrolysis. R. P. Barbier. Fr. Pat. 465,011, Nov. 18, 1913.

A porous mass of carbon is formed round a central carbon rod, by heating organic or mineral material in a closed vessel, and manganese or lead peroxide, or other active material is then fixed in the pores by chemical means or by the electrolysis of suitable solutions. In the latter case the electrolyte may be regenerated by the use of similar exhausted electrodes, either by an independent operation, or by connecting these with the negative pole during electrolysis.—B. N.

Insulating composition. Insulator. F. M. Locke, Victor, N.Y. U.S. Pats. 1,091,678 and 1,091,679, March 31, 1914.

(1) Aluminium silicate and a boron compound are fused together to form a homogeneous body. (2) A "vitrifiable base," such as silica, is fused with boron to form a homogeneous body.—B. N.

[*Electrical*] *Insulating composition.* L. E. Barringer, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,091,725, March 31, 1914.

The composition is used as a filler for oil-immersed electrical coils, and comprises, by weight, 82 parts of copal gum, 10 of castor oil, and 8 parts of resin extracted from crude rubber, to which colophony may be added. It possesses high insulating properties, remains liquid when heated, and is insoluble in mineral oil.—B. N.

Furnace: Electric crucible ——. D. F. Calhane, Worcester, Mass. U.S. Pat. 1,091,808, March 31, 1914.

An external wall of cement is provided with an inner one of asbestos filling, the latter having a partition of asbestos board between its inner and outer surfaces, and within the whole is an inner wall of solid insulating material with a cement bottom and an electrode on the base. Several removable and replaceable solid insulating blocks of alundum are placed one upon the other at the bottom of the furnace for supporting the crucible at different heights, and a continuous granular packing of carbon, acting as a resister, is placed around the blocks and crucible, a second upper electrode being in contact with the carbon packing. Several removable insulating rings of alundum are located one upon the other within the packing around the crucible for directing the current, and by varying the number of rings the heat may be concentrated along any desired portion of the walls of the crucible.—B. N.

Furnaces; Electric ——. F. T. Snyder. Fr. Pat. 465.188, Nov. 21, 1913.

The furnace, with heat-insulating refractory walls, is supplied with alternating current through a resister having a negative temperature coefficient, and the temperature is regulated by submitting the current to the influence of a "reactance," so that the energy which is developed diminishes with an increase of flux of the current through the resister. The "reactance" may consist of thin steel plates or rings enveloping the furnace, or be entirely at the exterior of the furnace in series with the resister, or a combination of the two methods may be used.—B. N.

Electrode-holder for electric furnaces. Ges. für Elektrostahlanlagen m.b.H. Fr. Pat. 464,396, Nov. 4, 1913.

The electrode is surrounded by two tubes; at the upper end the inner tube has a screw thread on its outer surface and the outer one a thread on its inner surface, whilst at the lower end the outer surface of the inner and the inner surface of the outer tube taper in opposite directions, so that by turning the outer tube the conical surfaces are forced together for maintaining a tight joint. A collar, also threaded, is screwed on to the top of the inner tube, and, by means of packing, maintains a tight joint between this tube and the electrode.—B. N.

Purification of gas by high-tension electric currents. Purifying gas by electricity; Process and apparatus for —— *by charging and depositing the particles in suspension.* G. A. Krause. Fr. Pats. 465,276 and 465,277, Nov. 24, 1913. Under Int. Conv., Nov. 25, 1912.

(1) The curves of the current are utilised to a greater extent by a division of the current, this being produced by an arrangement of several points and plates, fixed or movable, in contact with each other in the circuit. (2) Electrodes of the same polarity are employed at the places of charging and deposition, and the speed of the gas in the channel connecting the chambers containing the electrodes is greater than in the chambers themselves. Groups of electrodes, pivoted around an axis, may be employed as the collecting electrodes.—B. N.

Insulator. Insulating material. L. E. Barringer, Schenectady, Assignor to General Electric Co., New York. U.S. Pats. 1,091,620 and 1,091,621, March 31, 1914.

See Eng. Pats. 2128 of 1909 and 5156 of 1911; this J., 1910, 164; 1911, 1320.—T. F. B.

Electrical-insulating composition and method of preparing the same. J. W. Aylsworth, Assignor to Condensite Co. of America, East Orange, N.J. U.S. Pat. 1,092,511, April 7, 1914.

See Fr. Pat. 435,944 of 1911; this J., 1912, 446.—T. F. B.

Electro-osmotic operations; Process and apparatus for carrying out ——. Ges. f. Elektro-Osmose m. b. H. Fr. Pat. 464,714, Nov. 10, 1913. Under Int. Conv., July 21, 1913.

See Eng. Pat. 26,061 of 1913; this J., 1914, 206.—T. F. B.

Electrolysis of aqueous solutions; Process and apparatus for the ——. Soc. pour l'Industrie Chimique à Bâle. Fr. Pat. 465,128, Jan. 29, 1913.

XII.—FATS; OILS; WAXES.

Oil resources of the Empire. F. Mollwo Perkin. J. Roy. Soc. Arts, 1914, 62, 471—488.

Report, largely statistical and commercial of the oils, mineral, animal and vegetable, obtained within the Imperial area, and arranged both geographically and according to class or nature.

Fish oil from India. Bull. Imp. Inst., 1914, 12, 50—53.

As a result of experiments carried out by the Madras Government Fishery Department a local fish-oil industry has been established. In 1909 there was only one factory, but at the commencement of the 1911—1912 season between forty and fifty small factories were producing oil and guano from fish—principally sardines—in Malabar and South Canara. The fish is boiled in open pans holding ½ to ⅔ of a ton and is then pressed in coarse coir bags in simple screw presses; the guano is broken up and sun dried (see this J., 1914, 270). The crude oil fetches about £10 10s. per ton of about 250 galls. at the factory. A better market exists for finer grades of oil, and machinery has been installed at Tanur for producing pale-coloured oil, for separating the "stearine" and refining the oil. The analytical characters of a number of samples of the oil and one of the "stearine" are tabulated: they show that these oils would be suitable for the usual purposes to which fish oils are applied, such as leather dressing, etc.—R. G. P.

Natural and hardened [hydrogenated] fats; Unsaponifiable constituents of ——. J. Marcusson and G. Meyerheim. Z. angew. Chem., 1914, 27, 201—203.

Various natural fats, including tallow, whale oil, and vegetable oils, contained from 0·03 to 0·38 of cholesterol or phytosterol (determined by the digitonin method), the highest proportion being found in linseed oil and the lowest in tallow. The phytosterol constituted from 33 to 55 per cent. of the unsaponifiable matter of the vegetable oils, and the cholesterol from 8 to 14 per cent. of the unsaponifiable matter of the animal fats. The other constituents consisted in the main of dextrorotatory alcohols which neutralised, wholly or in part, the optical lævorotation of the cholesterol or phytosterol. For example, the sesamin in sesamé oil caused the unsaponifiable matter to have $[a]_D = +52°$. This characteristic may be used as a test of sesamé oil in cases where the colour reactions give negative results through previous treatment of the oil. The unsaponifiable matter, after removal of the cholesterol or phytosterol as digitonides, was a thick oily substance, containing dextrorotatory alcohols, with the exception of that from tallow which contained lævorotatory alcohols. Only in the case of dark marine animal oils (*Tranen*) were there more than traces of hydrocarbons. The unsaponifiable matter of sesamé oil freed from cholesterol showed $[a]_D = 102°$. The iodine value of the unprecipitated unsaponifiable matter of the fats examined ranged from 56 to 78, or about the same as that of the cholesterol or phytosterol (68). Small quantities of hydrocarbons may be detected by this test. As a rule hydrogenated fats contained less cholesterol or phytosterol than the original fats, the proportion decreasing with the degree of hardening. The other constituents of the unsaponifiable matter were yellow and semi-solid. From "talgol" and "candelite" a saturated alcohol was extracted with petroleum spirit. It melted at 59·3° to 59·8° C., and had the refraction at 100° C. of octodecyl alcohol (1·4268). On hydrogenation cholesterol was resinified to the extent of about 75 per cent. at 200° C., whilst phytosterol was not appreciably affected. At 250° C. cholesterol no longer yielded crystalline derivatives, though these could still be obtained from phytosterol. This explains why cholesterol cannot be precipitated with digitonin from "talgol" and similar products from animal fats.—C. A. M.

Rubber substitutes. Ditmar. *See* XIV.

PATENTS.

Animal matter containing moisture, oil, or grease; Apparatus for treating ——. G. F. Metzger, Lakewood, Ohio. U.S. Pat. 1,091,524, March 31, 1914.

THE material is heated, by means of steam pipes in a perforated casing which can be separated into sections, means being provided for draining off liquid from the space between the casing and the outer wall of the tank, which is connected at the top with an exhaust fan. —C. A. M.

Oleic and other fatty acids derived from train or fish oils; Process for deodorising ——. W. H. Hofmann, Hamburg, Germany. Eng. Pat. 21,478, Sept. 23, 1913. Under Int. Conv., Sept. 28, 1912.

SEE Fr. Pat. 462,763 of 1913; this J., 1914, 324.—T. F. B.

Sterilisation of liquids [*and bleaching oils, by ultra-violet rays*]. Addition to Fr. Pat. 403,945. *See* XIXB.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Chemical utilisation of Southern pine waste. Whitaker and Bates. *See* V.

PATENTS.

Lakes; New colour ——. P. A. Newton, London. From Farbenfabriken vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 15,557, July 5, 1913.

PIGMENTS of bluish red shade and fast to light are produced from the aluminium compounds of sulphonic acids of purpurin or purpurin-amide. The substratum may be the excess of aluminium hydroxide from the preparation of the lake, or any other substance, *e.g.*, barium sulphate. —J. B.

Turpentine; Separating apparatus for ——. *Turpentine-condenser.* H. L. Hough, Redlevel, Fla. U.S. Pats. 1,092,051 and 1,092,052, March 31, 1914.

(1). THE material is introduced into a perforated separating receptacle disposed at the top of a tank and above the first of a series of settling compartments in the bottom of the tank; and is there subjected to the action of a steam spray. (2). The vapours are condensed in a chamber surrounded by water or other medium and having a hopper-shaped bottom in which is an opening through which the condensed liquids fall into a lower chamber provided with means for separating the turpentine from the condensed water.—C. A. M.

White lead; Process of producing ——. E. Euston, St. Louis, U.S.A. Eng. Pat. 21,848, Sept. 27, 1913.

SEE U.S. Pat. 1,075,143 of 1913; this J., 1913, 1077.—T. F. B.

Alumina colour-lake; Red ——. *Red alumina colour-lakes obtained from aminoxanthopurpurinsulphonic acids.* C. Thun, Elberfeld, P. Tust and P. Thomaschewski, Vohwinkel, Germany, Assignors to Synthetic Patents Co., New York. U.S. Pats. 1,090,352 and 1,090,353, March 24, 1914.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber substitutes. R. Ditmar. Gummi-Zeit., 1914, 28, 998—1000, 1032—1034, 1070—1077.

THE author suggests that the elasticity of rubber substitutes may be measured by placing the powdered substance in a cylindrical vessel, and allowing it to be compressed by a loaded piston, noting the depression and the recovery on subsequently removing the load. Details are given of a large number of experiments in preparing substitute from rape oil. 50 grms. oil were mixed with sulphur and with different additions (paraffin, mineral oil), with stirring, in a flat porcelain dish, and heated on an air bath till the reaction began, when the mixture foamed: the temperature was then usually about 195°—200° C. The reaction usually lasted for at least 3 mins., the temperature rising to about 220°—230° C. The hot mass was poured on a glass plate, and the product tested after 24 hours. It was then stored for about 80 days and again tested for appearance, elasticity, etc. With unoxidised rape oil the best result was obtained by adding 32 per cent. of sulphur (calculated on the amount of oil). The product was not so good if less than 28 per cent. of sulphur was used. Using rape oil which had been oxidised by blowing in air for 5 hrs. at 250° C., good results were obtained with 18 per cent. of sulphur; one of the best products was made with 22 per cent. of sulphur. A considerable number of experiments were made with both oxidised and unoxidised rape oil with the addition of varying quantities of mineral oil. Analyses were made of the products usually more sulphur was lost by volatilisation, and the acetone extract (8 hrs.) and free sulphur were higher in the case of the unoxidised oil.—H. E. P.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin; Colloid-chemical studies on ——. M. Navassart. Kolloidchem. Beihefte, 1914, 5, 299—374.

Experiments with a number of samples of the purest commercial tannin, of different origin, showed that tannin has no definite solubility in water, alcohol, acetone, commercial glacial acetic acid, and formol, but is miscible therewith in all proportions, forming gelatinous masses at high concentrations: in this respect tannin resembles colloids of the emulsoid type, such as gelatin. It is practically insoluble in ether, chloroform, benzene, petroleum ether, carbon tetrachloride, carbon bisulphide, and xylene. The density of aqueous solutions of tannin of all concentrations, and of solutions in organic solvents for concentrations up to 20 per cent., is a linear function of the concentration: in this respect tannin behaves more like a suspension-colloid. The specific optical rotation of tannin increases considerably in aqueous solutions as the solution is diluted; in organic solvents the rotatory power is lower and does not vary much at different concentrations. The viscosity of aqueous solutions containing 10—12 per cent. of tannin is only slightly higher than that of pure water; above 18 per cent. it rises rapidly, and at 30 per cent. is 9—10 times greater than that of water, whilst at 60 per cent. a jelly is formed. Solutions in organic solvents are more viscous than aqueous solutions at the ordinary temperature. The results of experiments on the dialysis, ultramicroscopic examination, etc., of tannin solutions are also described, and it is concluded that aqueous tannin solutions exhibit properties intermediate between those of a true solution and a colloidal solution, and between those of suspensoid and emulsoid sols.—A. S

Tans (*phlobaphenes*). *Powdered* —— *and different reactions of hydrolysis* (*photolysis*). E. O. Sommerhoff. Collegium, 1914, 81—84. (See also this J., 1914, 152.)

Sparingly soluble tannins (*e.g.* gambier and quebracho) are best dissolved by moistening first with a little cold water and then making into a paste with warm water. Sudden treatment with much hot water has the effect of essening their solubidity. Tannins have an opposite lectric charge to that of animal blood and the author has hown that a third substance such as alcohol has a favourble influence on the oxidation process of two colloids f opposite electric charges such as albumin and tannin. 0 per cent. of pure finely divided sulphur added to the nsulphited quebracho extract in a large tumbler in hich 100 kilos. of calf skins were being tanned caused he whole of the interior of the drum to be filled with sulphur dioxide and the goods, even after lying for a day, had still a distinct odour of sulphur dioxide. The sulphur may have derived its oxygen either from the air or from the hydrated tannins. In the latter case the tannins as they penetrated the hide not only electrically neutralised the hide albumin but also yielded up oxygen, becoming reduced. By lying in damp air secondary photochemical oxidation takes place by which the hide albumin and also the quebracho tannin are further oxidised and become completely insoluble. The time of hanging and the intensity of the light is therefore of great importance as regards the resistance of the leather to hot and cold water. The long boiling of gambier as usually practised in tanning and silk-dyeing causes a hydrolytic decomposition of the phlobaphenes. The hydrolysis is greatly accelerated by light and air as the hydrogen ions of the water are activated by the oxygen of the air in the presence of the light energy. The action of soap solutions on linen is also greatly intensified by sunlight. Water in the presence of air and direct sunlight acts upon colloids forming hydrogen peroxide.—D. J. L.

Tanning materials; Colour valuation of ——. H. C. Reed. J. Amer. Leather Chem. Assoc., 1914, 9. 170—174.

In making colour valuations of tanning materials, using pelt, the latter is always tanned completely, excess of colouring matter thus being present. As skin absorbs colouring matters selectively this gives fallacious results. It is impossible to obtain pelt of sufficient uniformity to give concordant results. The use of hide powder is again advocated. The squeezed hide powder after use in the official method of tannin analysis is broken up and allowed to dry in the dark and the colour of the powder taken as an indication of the colour value of the material. The chroming of the hide powder has little influence on the colour.—T. C.

Picric acid and quinone; Tanning with ——. E. O. Sommerhoff. Collegium, 1914, 225—229.

Picric acid is rapidly absorbed by hide, colouring it yellow and some tanning action takes place. Quinone colours hide very slowly violet (better in presence of light) and this changes gradually to brown with accompanying tanning action. Picric acid tans without being constitutionally changed, whilst with quinone the reverse is the case. Laboratory tanning experiments are considered to correspond with picric acid tanning, *i.e.* tanning action without constitutional change in the tanning material, whilst in actual practice the tanning process proceeds, as with quinone, with simultaneous constitutional change in the tanning material. In picric acid tanning the oxidation of hide albumin takes place on drying the leather, whilst with quinone, oxidation takes place in the tan bath. In quinone tanning it is very probable that water chemically combined with hide albumin is decomposed with formation of quinol (hydroquinone) and oxidised albumin: the quinol is subsequently re-oxidised at the expense of the oxidised albumin or of the air, the process being considerably affected by light.—T. C.

Harness leather; Growth of mould on ——. A. Seymour-Jones. Leather Trades Rev., Feb., 1914. J. Amer. Leather Chem. Assoc., 1914, 9. 180—186.

A piece of harness leather on keeping developed raised nodules although the grain was not damaged. These were due to the growth of roots of *Penicillium glaucum* on the sebaceous gland layer (*stratum sebaceum*), the spores having entered through the hair holes. It is recommended that mouldy leather should be scoured with hot water containing 0·5 to 1 per cent. of formic acid or sponged with 1 per cent. formic acid.—T. C.

XVI.—SOILS ; FERTILISERS.

Fish guano from India. Bull. Imp. Inst., 1914, **12**, 53—55.

Three samples of fish guano prepared at the Madras Government Fisheries Station were examined. They contained about the same percentage of nitrogen and an average amount of phosphoric anhydride when compared with commercial fish manures ; and average amounts of fat and phosphoric anhydride, but a somewhat smaller amount of protein when compared with commercial fish meals used for cattle and pig feeding.—R. G. P.

Fertilisers ; Experiments with ——. C. E. Thorne and E. Mohn. Ohio Stat. Bull. No. 260. 405—448. Expt. Stat. Record, U.S. Dept. Agric., 1914, **30**, 25.

The experiments, begun in 1895 and still in progress, were made on a cold heavy, clay soil lying over compact argillaceous shales. Phosphate fertilisers proved more valuable than nitrogenous or potash fertilisers, especially in the earlier years: acid phosphate (superphosphate) and steamed bone-meal were about equally effective. Mixtures prepared as required from tankage, superphosphate, and muriate of potash were more effective and much cheaper than commercial mixed fertilisers. In the earlier years the yield of clover was increased by application of phosphate, but more recently good results could only be obtained after application of limestone.—A. S.

XVII.—SUGARS ; STARCHES ; GUMS.

Sugar cane ; Natural colouring matters of the ——, and their influence in the manufacture of white sugar. C. Muller. Bull. Assoc. Chim. Sucr., 1914, **31**, 647—652.

Chlorophyll, anthocyan (the red colouring matter present in dark canes), and the yellow pigment or chromogen of the bagasse do not appear to interfere much with the production of white sugar ; the colouration of syrups is mainly due to other causes, probably to unknown colouring matters. Chlorophyll is insoluble in water. Anthocyan though very soluble and possessing considerable tinctorial power (red in acid and green in alkaline solutions), is decomposed very rapidly after the crushing of the cane, and very small quantities only are present in the juice ; none remains in the bagasse. The yellow colouring matter of the bagasse is much more stable than anthocyan but only slightly soluble in water. It is yellow in presence of alkalis but decolourised by acids. The greater part of that present in the juice passes into the scum and the defecation mud. Sulphitation appears to have little effect on these colouring matters, but carbonatation and phosphatation suffice to remove all that may have passed into the juice.—J. H. L.

Heat balance of a cane sugar factory. N. Deerr. Hawaiian Sugar Planters' Assoc, Expt. Stat., Bull. No. 43, Agric. Chem. Series, 1914.

The amounts of steam required for power and for heating purposes in an Hawaiian cane sugar factory of high efficiency were determined, using the following data: 100 short tons of cane produced 50,000 lb. of bagasse and 110 tons of juice, and the combustion of the bagasse gave 130,000 lb. of steam, the ratio of steam formed to fuel burnt being 2·6. *Power.*—The following values for the I.H.P. per 100 tons of cane per hour were obtained : Mill engines, 1112 ; quadruple evaporator pump, 43 ; vacuum pump, 66 ; crystallisers, 24 ; centrifugals, 111 ; juice-heater pump, 8 ; and other motors, 46 ; a total of 1410 I.H.P., which corresponded with 7330 lb. of steam or 5·6 per cent. of that from the boilers. *Juice-heaters.*—Before entering the evaporators, the juice was heated from 82° to 212° F. (from 27·8°—100° C.), cooled to 202° F. (94·4° C.), and reheated to 212° F. (100° C.). Taking the specific heat of the juice to be 0·9, the amount of steam required was 30,590 lb., or 23·4 per cent. of that from the boilers. *Quadruple evaporator.*—Juice at 13° Brix was concentrated to 65° Brix. Assuming that 1 lb. of steam evaporated 4·2 lb. of water in the effect apparatus used, the steam required to remove 176,000 lb. of water was 41,859 lb., or 32·5 per cent. of that from the boilers. *Vacuum pans.*—If 1 lb. of steam evaporated 1 lb. of water in the pans, to eliminate the remaining water, namely, 15,000 lb., the steam required was 15,182 lb. or 11·6 per cent. of that coming from the boilers. The total amount of steam required was thus 94,952 lb., or only 73·1 per cent. of that from the boilers. In a factory in which the working was inefficient, though not extremely so, the bagasse only produced 110,000 lb. of steam, and the steam used at the different stations was :—*Power.*—7330 lb., or 6·7 per cent. *Juice-heaters.*—37,145 lb., or 33·7 per cent. *Quadruple evaporators.*—45,350 lb., or 41·2 per cent. *Vacuum pans.*—19,470 lb., or 17·7 per cent. The total was thus 109,295 lb. of steam, or 99·3 per cent. of that coming from the boilers, under which circumstances the factory would barely be able to work without extra fuel. The factors for ensuring efficiency in heat economy in the sugar factory are as follows : ample heating surface in boilers ; control of the bagasse fuel combustion ; insulation of hot surfaces ; the use of evaporators of sufficient heating surface readily to obtain a syrup of a density not less than 65° Brix ; and the application of the "extra steam" and multiple heating systems.—J. P. O.

Sugars ; Determination of reducing —— in sugar fo melting ("*sucres de fonte*"). C. Muller. Bull. Assoc Chim. Sucr., 1914, **31**, 646—647

From 10 to 20 grms. of the sample, dissolved in 20 c.c. o hot water, are heated with 50 c.c. of Fehling's solutio for 10 mins. at 63°—65° C., then mixed with 50 c.c. o cold water and filtered. The filter (diam. 10 cm.) is washe and introduced into 5 c.c. of hydrochloric acid and afte the precipitate has dissolved, the liquid is treated wit 10 c.c. of aqueous ammonia (sp. gr. 0·925) and titrated t a pale lilac tint with potassium cyanide solution (45 grms. per litre). The cyanide solution is standardised by diluting 24 c.c. of Fehling's copper sulphate solution (69·28 grms. $CuSO_4,5H_2O$ per litre) to 100 c.c., and titrating 10 c.c., which correspond to 0·025 grm. of reducing sugar, after addition of 5 c.c. of hydrochloric acid and 10 c.c. of ammonia. The filter paper retains a small quantity of copper solution, usually corresponding to 0·3—0·4 c.c. of the cyanide solution; this can be determined once for all and a correction made. When only small quantities of reducing sugars are being determined, it is unnecessary to re-oxidise the precipitated cuprous oxide with potassium chlorate before addition of ammonia. —J. H. L.

Reducing sugars contained in cane molasses; Origin of the ——. H. Pellet. Intern. Sugar J., 1914, **16**, 172—176.

Ripe and uncut sugar cane always contains a very variable amount of reducing sugars, which may increase during the treatment of the juice by the defecation-sulphitation process of clarification, especially during the concentration of the juice and the working-up of the after-products. The amount of the increase is usually 0·1—0·3 per cent. of the cane. There can be no decrease in the quantity of reducing sugars during manufacture, using the defecation process, and any such differences must be attributed to errors in nalysis and sampling.—J P. O.

Maple products; Analysis of ——. *IV. Composition of maple sugar sand.* J. F. Snell and A. G. Lochhead. J. Ind. Eng. Chem., 1914, **6**, 301—302.

Six samples (from Quebec) of washed, air-dried maple ugar sand contained from 65—80 per cent. of normal alcium malate, 6—18·5 per cent. of silica, minor quantities f manganese, magnesium, and phosphorus, traces of iron, nd 10—17 per cent. of undetermined matter. (See also Varren, this J., 1911, 980.)—A. S.

Gums from Northern Nigeria; "Golawai," "Katalabu," and "Kol-kol" ——. Bull. Imp. Inst., 1914, **12**, 27—31.

The results of the examination of 3 samples of "Golawai" um from *Acacia camphylacantha*, Hochst., 2 of "Katalabu" um from *A. Sieberiana*, D.C., and 3 grades of "Kol-kol" um from *A. Senegal*, Willd., are shown in the following able :—

e "golawai" gum was valued at 15s.—17s. 6d. per cwt. a "semi-insoluble" gum. "Katalabu," a glassy gum the "soluble" type, gave a yellowish brown mucilage h good adhesive properties, and was valued at 22s. 6d. 24s. per cwt., with "glassy Khartum" gum at 31s. cwt. (April 1913). "Kol-kol" gum closely resembled rdofan gum but gave rather darker solutions: the ole consignment was sold at 30s. per cwt. (Dec. 1913). —R. G. P.

trin; Solubility of ——. W. K. Lewis. J. Ind. Eng. Chem., 1914, **6**, 308—309.

Weighed quantities of dextrin were agitated with asured quantities of water, and the insoluble residue separated by centrifuging. The results showed that with increasing quantities of water, the amount of dextrin dissolved increased continuously, although in no case was the whole of the dextrin dissolved, and the concentration of the solution did not remain constant no matter how small a quantity of water was used. It is suggested that this behaviour may be due to adsorption of a soluble by an insoluble constituent, in which case the equation: $\log(A-x)=\log k+\frac{1}{n}\log c$ should hold, A representing the total soluble portion, x the soluble portion actually dissolved, c the concentration of the solution, and k and n constants, characteristic of the dextrin employed, and offering, in the author's opinion, a better means of distinguishing between different samples of dextrin than any other method hitherto suggested. In applying the method, values of x and c are determined experimentally, and a value for A chosen such that a straight line is obtained when values of $\log(A-x)$ are plotted against values of log c: the slope of the line gives the value of $\frac{1}{n}$ and the intercept of the line, the logarithm of k.—A. S.

Sugar juices; Process and apparatus for freeing —— *from fibrous and suspended matters.* Maschinenfabrik Grevenbroich. Fr. Pat. 464,897, Nov. 13, 1913. Under Int. Conv., Dec. 9, 1912.

Raw sugar juices obtained by maceration or pressing are passed in a wide shallow layer across the surface of a large volume of resting liquid into which the suspended matters sink. The height of the moving layer may be regulated by a series of transverse adjustable baffle-plates, which, sloping downwards in the direction of flow of the liquid, serve to confer a downward motion on the particles. The lower part of the reservoir is divided into several funnel-shaped chambers, each with an outlet at the bottom for drawing off the matters which have subsided.—J. H. L.

[*Sugar*]. *Extraction of certain soluble substances contained in the cells of certain plants.* M. Paquier, C. Théry and E. Gallois. Fr. Pat. 464,947, Jan. 25, 1913.

The vegetable material is partially or completely desiccated by the action of heat and reduced pressure, so as to effect the coagulation of substances coagulable by heat but not to render soluble those which become soluble at high temperatures. The material is subsequently extracted, at the ordinary temperature, with water or other solvents. The process is specially applicable to the extraction of sugar from beetroots.—J. H. L.

Sugar juices; Catalytic process effecting a purification of —— *at least equal to that produced by ordinary double carbonatation, and at the same time reducing by more than* 50 *per cent. the weight of lime employed.* H. Manoury. Fr. Pat. 465,270, Nov. 24, 1913.

The greater part of the lime used for defecation is replaced by relatively small quantities of other oxides such as those of iron, manganese or aluminium. Salts of these metals (sulphates, sulphites, chlorides) may be added to the juices, and the corresponding oxides precipitated by lime; when sulphates are employed sufficient baryta to precipitate the sulphuric acid is also added. For example, fresh juices may be treated with 1 grm. of ferrous sulphate crystals per litre, heated to 80° C., agitated with 3 grms. of lime per litre and a quantity of barium carbonate equivalent to the sulphate added, heated to 100° C. and filtered, and the lime remaining in the juice saturated by carbonatation (more lime being added if necessary) or sulphitation.—J. H. L.

Sugar factories and refineries ; Apparatus for the crystallisation and stationary draining of massecuites of ——. M. E. R. J. M. Lambert. Fr. Pat. 465,348, Nov. 26, 1913.

A number of fixed troughs are disposed parallel to each other at short distances apart, so that cold air can circulate freely around them during the crystallisation of the massecuite. Hinged to the back of each trough is a shutter which, when swung back horizontally, engages the front of the next trough. The space below and between the troughs then constitutes a closed chamber which can be heated by admission of steam in order to diminish the viscosity of the molasses during the draining of the crystals.—J. H. L.

[Sugar.] Evaporators [e.g., of the Kestner type] ; Device for preventing the juice from rising above a definite level in film ——. Sudenburger Maschinenfabrik und Eisengiesserei A.-G. zu Magdeburg. Ger. Pat. 270,876, Dec. 24, 1912.

A double-seated valve is inserted in the inlet pipe for the juice and is connected by a rod with a float placed at the maximum height for the juice level : the entering juice forces the valve downwards off its seating, flows into the evaporator and rises in the tube connecting the float-chamber with the inlet-pipe. If the juice rises above a definite height, the float rises and closes the double-seated valve, thus shutting off the supply of juice. If the level of juice in the evaporator falls too low, the pressure rises owing to stronger evaporation, and a steam-pressure regulator shuts off the supply of steam.—A. S.

XVIII.—FERMENTATION INDUSTRIES.

Yeast fermentation without sugar. XIV. Further investigation of carboxylase. C. Neuberg and P. Rosenthal. Biochem. Zeits., 1914, 61, 171—183.

Further evidence is adduced for the existence of carboxylase as an enzyme distinct from zymase (cp. this J., 1911, 1179 ; 1913, 620). The nitrogenous precipitate produced by addition of acetone or alcohol and ether to yeast maceration juice contains not only zymase, but carboxylase which exhibits great activity even after the precipitate has been dried and redissolved in water. Carboxylase ferments oxalacetic acid and its salts under conditions which completely arrest the fermentation of sugar. It is the first enzyme known to liberate carbon dioxide from carboxylic acids.—J. H. L.

Tricresol as a substitute for toluene in enzyme work. S. S. Graves and P. A. Kober. J. Amer. Chem. Soc., 1914, **36**, 751—758.

Tricresol, neutralised if necessary by sodium hydroxide, is considered to be superior to toluene on account of its solubility in water, lower volatility, and more powerful germicidal action. For trypsin, pepsin, urease, and diastase, concentrations up to 0·5 per cent. are recommended ; for erepsin and invertase, 0·2 per cent.—F. Sodn.

[Beer] Original gravity ; The ebullioscope in the determination of ——. T. H. Pope. Brewers' J., 1914, **50**, 239—242 (cp. Cain, this J., 1914, 156.)

The thermometer scale of the ebullioscope or alcoholmeter employed, is calibrated to show the change in gravity of the beer due to fermentation, so that the sum of the value thus obtained and the gravity of the beer itself, represents the original gravity. In use, the mercury thread of the instrument first rises to a maximum and then falls slightly to a point at which it remains constant for some time ; this point should be taken as the reading. The unfermented matter in the beer vitiates the reading appreciably only in the neighbourhood of the zero point, the error disappearing at those parts of the scale where the readings with beers are taken. The method is accurate and much more expeditious than the ordinary distillation method.—L. E.

Tartar ; Crystallisation of cream of —— *in the fruit of grapes.* W. B. Alwood. J. Agric. Res., 1914, **1**, 513—514.

The soft cells lying immediately beneath the skin of the grape contain a higher proportion of tartaric acid and potassium bitartrate than the interior pulp ; potassium bitartrate occurs in these cells in the form of minute crystals.—L. E.

Unfermented grape juice in California ; Manufacture o ——. W. V. Cruess and C. J. Hintze. J. Ind. Eng Chem., 1914, **6**, 302—304.

As a result of an experimental investigation some modifications of the method of manufacture of unfermented grap juice as practised in California are suggested. A mixtur of ripe grapes, to give flavour, with grapes of high acidit should be used and potassium metabisulphite (8—12 o. per ton of grapes) added at the crusher to prevent fermen ation. After defecation (settling) for 24—48 hours, t juice should be racked off, clarified by means of casei (4—6 oz. per 100 galls.) dissolved in sodium carbonate ammonia, treated with a small quantity of tartaric ac (0·1—0·2 per cent.) to facilitate separation of cream tartar, heated to 165° F. (74° C.) and stored in barre When most of the excess cream of tartar has separated, t juice should be racked off, filtered if necessary, treat with a small quantity of citric acid (0·05—0·1 per cen to prevent further separation of cream of tartar, a pasteurised in bottles at 160° F. (71° C.).—A. S.

Cider ; Disease of —— *known as green-sickness* [" *verdis ment* "]. Warcollier. Comptes rend., 1914, **158**, 97 976.

This disease generally appears at the beginning of mentation in ciders characterised by low contents of m acid, tannin and nitrogenous bodies, and a rather h content of mineral matter, especially lime. The affected ciders contain nitrites formed either from nitrates in the water used for extracting the pressed pulp, or by exposure of the pulp to air; the fresh pulp contains no nitrite. The nitrites oxidise the tannin, and the olive-green colour characteristic of the disease is due to combination of the oxidised tannin with a ferrous salt. The disease arrests fermentation although an abundant deposit of yeast is obtained. To prevent the disease, water of high nitrate-content should not be used, fruit soiled with earth or organic matter should be washed, the pulp should not be exposed too long to the air, and prolonged contact of the pulp, marc, or juice with iron utensils should be avoided. —L. E.

Methyl alcohol; Colour reaction for the detection of ——. C. D. Manzoff. Z. Unters. Nahr. Genussm., 1914, 27, 469—470.

When a mixture of nitromethane, ammonia, and vanillin is heated, a red colouration is produced which disappears on cooling; under similar conditions, nitroethane yields only a faint yellow colouration. The test will detect the presence of 1 part of nitromethane in 100,000 parts of nitroethane. The intensity of the colouration obtained depends, to a certain degree, on the quantity of vanillin employed. Other aliphatic and aromatic aldehydes and ketones do not give a colouration with nitromethane, with the exception of *p*-hydroxybenzaldehyde, which yields an orange-red colour. To detect methyl alcohol in ethyl alcohol, 200 c.c. of the spirit are mixed with 5 c.c. of phosphoric acid, distilled, and the first 5 c.c. of distillate heated with 5 grms. of red phosphorus and 20 grms. of iodine for 20 minutes under a reflux condenser, and distilled. The distillate is treated with 3 grms. of silver nitrite, again distilled, the first 5 drops of distillate mixed with 5 drops of ammonia and 0·01 grm. of vanillin, and the mixture heated. A red colouration indicates the presence of methyl alcohol in the spirit.—W. P. S.

Freezing of wine, milk, and other alimentary fluids. Parenty. *See* XIXa.

Patents.

Pasteuriser for malt beverages, wines, aerated waters and other liquids. H. Erikson, Askersrend, Sweden. Eng. Pat. 20,016, Sept. 4, 1913.

The pasteurising vessel is jacketed and contains a coil. Heating and cooling media are supplied and discharged hrough single pipes branched near the apparatus, one ranch being connected with the coil and the other with he jacketed space. The apparatus is supported by runnions on trestles and can be rocked in a vertical lane.—L. E.

Beer; Manufacture of non-alcoholic ——. K. Kroupa, Rannersdorf, Austria. Eng. Pat. 29,314, Dec. 19, 1913. Under Int. Conv., Dec. 19, 1912.

Mixture of beer and hopped beer wort is heated to xpel alcohol and then carbonated.—L. E.

ugars [from cellulosic material]; Process of producing fermentable ——. F. E. Gallagher, Newton, Mass., Assignor to Standard Alcohol Co., New York. U.S. Pat. 1,091,327, March 24, 1914.

the production of fermentable sugars from cellulosic aterial, the spent wort is mixed with the soluble products hydrolysis of the cellulosic material, and the whole is rther hydrolysed.—L. E.

ucose and ethyl alcohol from sawdust or other cellulosic materials; Production of —— A. de Posnansky. Fr. Pat. 464,502, Jan. 14, 1913.

HE material is heated in an autoclave, first with free lphurous acid and then with the acid in presence of an excess of alkali, in particular ammonia. After washing, saccharification is effected by heating under pressure with an acid, preferably sulphuric acid, and the saccharine liquid is purified by addition of aluminium compounds and tannin, and removal of the latter by means of albumin or gelatin; by addition of alkaline-earth carbonates, sodium phosphate and alum; by treatment with reducing substances, *e.g.*, sulphites, thiosulphates, zinc or zinc hydrosulphite, and in the last two cases subsequent addition of carbonates and sodium phosphate; by addition of litharge in slight excess, afterwards removed; by separation of the sugar and salts from the resinous and empyreumatic substances by dialysis; or by filtration. The purified juice is concentrated by evaporation, distillation under a layer of vaseline, paraffin, etc., or freezing, and afterwards either fermented, or worked up for glucose by evaporating to dryness at a low temperature, extracting with hot alcohol and collecting the glucose which separates on cooling.—J. H. L.

Saccharification of starch; New organism and its application to the —— *and the manufacture of alcohol, vinegar, wines and other products derived from the saccharification of starch.* Société d'Exploit. des Procédés H. Boulard. Fr. Pat. 464,601, Oct. 29, 1913.

Starch is saccharified by means of a mould, *Mucor Boulard No.* 5, which occurs in large quantities on plants in the Far East. The mycelial threads exhibit transverse membranes, and pear-shaped enlargements at their ends which become detached in old cultures. Potato starch and cereal starch, after a suitable treatment (heating under pressure), are saccharified with equal ease by this organism, which is so robust that bacterial infection is not to be feared, and saccharification can be carried out in open vats at temperatures as high as 45° or as low as 20° C.—J. H. L.

Fusel oil; Process of producing ——. J. Scheckenbach, Munich, Germany. Eng. Pat. 20,942, Sept. 16, 1913. Under Int. Conv., Sept. 21, 1912.

See Fr. Pat. 462,472 of 1913; this J., 1914, 329.—T. F. B.

Distillery-vinasses; Extraction of glycerin and fatty matters contained in ——. G. P. Guignard, Melun, and H. L. A. M. Watrigant, Lille, France. U.S. Pat. 1,092,791, April 7, 1914.

See Fr. Pat. 427,560 of 1910; this J., 1911, 1134.—T. F. B.

Mannite from natural musts; Process for making ——. G. P. Guignard. Fr. Pat. 464,644, Jan. 17, 1913.

Separation and recovery of volatile acids, methyl compounds, and furfuran bodies from hydrolysed lignocelluloses. Fr. Pat. 464,608. *See* V.

XIXa.—FOODS.

Sucrose in presence of lactose and in milk preparations; Determination of ——. J. N. Rakshit. J. Ind. Eng. Chem., 1914, 6, 307—308.

The lactose is first determined by titration with Fehling's solution, then a measured quantity of Fehling's solution is boiled with the calculated quantity of the sugar solution so as to precipitate the copper and decompose the lactose, the mixture is filtered, and the sucrose in the filtrate determined as usual after inversion and neutralisation. Milk and solutions of milk preparations are first coagulated by addition of dilute citric acid, drop by drop, shaking well between successive additions. Results are given showing the accuracy of the method.—A. S

Alimentary liquids ; Freezing of wine, milk and other ——. H. Parenty. Comptes rend., 1914, **158**, 921—922.

Liquids may be concentrated by freezing and centrifuging more economically than by evaporation, provided that, corresponding to the multiple effects in the latter process, the frozen residues are utilised for further refrigeration. The process, which has been used for the concentration of wine and milk, insures the retention of volatile constituents in the liquid, aids clarification, and does not alter the flavour, aroma, or colour.—L. E.

Butter fat ; Detection of cocoanut oil in —— *by means of Polenske's distillation method and Bömer's phytosteryl acetate method.* C. Barthel and K. Sondén. Z. Unters. Nahr. Genussm., 1914, **27**, 439—453.

Numerous samples of Swedish butter examined during the years 1904—1912 never gave a Polenske value exceeding that fixed by Polenske as the maximum value for genuine butter, *i.e.*, 3·5 when the Reichert-Meissl value was 30. This method was capable of detecting 10 per cent., and in some cases 5 per cent., of cocoanut oil in butter-fat, but could not be relied upon in all cases, since butter obtained from cows fed on beetroot leaves or cocoanut oil cake (not more than 2 kilos. per animal per day) gave a Polenske value which exceeded the limit. Bömer's phytosteryl acetate method yielded reliable results even in the case of butter from cows fed on beetroot leaves, cocoanut oil cake, etc.—W. P. S.

Fat ; Rapid determination of —— *in cheese, butter and cream.* K. Kropat. Arch. Pharm., 1914, **252**, 76—82.

Cheese.—From 2 to 3 grms. are heated with 5 c.c. of 25 per cent. hydrochloric acid until a brown solution is obtained, 3 to 5 c.c. of alcohol are added, the mixture cooled, and shaken with 25 c.c. of ether until the layers separate, when 25 c.c. of petroleum spirit are added and the extraction completed. After standing 10 to 15 mins., from 1 to 1·5 grms. of gum tragacanth and 3 to 5 c.c. of water are introduced into the separating funnel, which is rotated until the gum swells up, and then vigorously shaken until coagulation of the gum takes place. The clear ethereal layer is drawn off, the residue washed with petroleum spirit (15 c.c.), the extract and washings evaporated, and the residue dried for 2 hours and weighed. *Butter.*—1 grm. is gently warmed with 3 to 5 c.c. of water, 3 to 5 c.c. of alcohol added, and, after cooling, the fat is extracted with 20 c.c. each of ether and petroleum spirit, the casein coagulated by shaking with 1 grm. of gum tragacanth and 1 to 3 c.c. of water as described, the extract evaporated, and the residue of fat weighed. *Cream.*—From 2 to 5 grms. are treated with about 3 c.c. of ammonia solution and 3 to 5 c.c. of alcohol and shaken with 20 c.c. each of ether and petroleum spirit (with the subsequent addition of 3 to 4 c.c. of water in the case of sour cream). After 10 to 15 mins. 1 to 1·5 grms. of gum tragacanth are added, with 3 to 4 c.c. of water (if not already added) and the fat separated as described.
—C. A. M.

Malt coffee. F. Doepmann. Z. Unters. Nahr. Genussm., 1914, **27**, 453—466.

Malt coffee should be prepared from roasted malt: commercial products sometimes consist of roasted barley. For distinguishing between the two, the examination of the grains as regards their degree of germination is recommended. In the case of roasted malt, the length of the germ may equal or exceed the length of the grain, and from 70 to 90 per cent. of the grains exhibit some signs of germination. In two samples of roasted barley only 8 per cent. of the grains showed signs of germination.
—W. P. S.

Feeding-stuffs and food products ; Preparation of new cheap ——. O. Nagel. Z. angew. Chem., 1914, **27**, 208.

Castor oil-cake may be completely freed from the poisonous ricinin by repeated washing with 5 to 10 per cent. sodium chloride solution, until the washings no longer show any precipitate on heating. The mass is then centrifuged and dried for use as a feeding-stuff. Many oil-cakes, and especially that from rape seed, may be used as a cheap source of albumin. The fresh fat-free cake is extracted with water, the solution of albumin evaporated, and the residue dried at a low temperature. A product of finer quality is obtained in this way from sesamé oil-cake, while cocoanut and arachis oil-cakes yield readily digestible and very soluble albumins. Cottonseed oil-cake gives an albumin of dark colour and unpleasant odour, to remove which filtration through animal charcoal is required. The vegetable casein in soya bean oil-cake may be separated by treatment with dilute alkali solution, and precipitation with rennet or an acid. The cost of 100 kilos. of albumin in oil-cakes is estimated at less than M. 50 (£2 9s.).—C. A. M.

Patents.

Butter ; Purification of ——. E. B. Higgins, Liverpool. Eng. Pat. 15,221, July 2, 1913.

Rancid butter or butter contaminated with mechanical impurities is agitated at a low temperature, *e.g.*, 9° C., with an equal weight of a 2·5 per cent. solution of sodium carbonate. The mixture is allowed to settle, the deposited impurities drawn off, the butter strained from the liquid and washed 4 or 5 times with a 0·5 per cent. solution of common salt. The sodium carbonate may be replaced by other suitable alkalis, and the wash water may be slightly acidified, *e.g.*, with hydrochloric acid.—L. E.

Flour ; Process of bleaching ——. J. A. Wesener. Fr. Pat. 465,300, Nov. 25, 1913.

The flour is treated with a mixture of nitrosyl chloride and chlorine obtained from a liquefied mixture of the gases stored under pressure.—W. P. S.

Cotton seed ; Manufacture of food from cakes made from ——. Molassine Co., Ltd., East Greenwich, and J. J. A. de Whalley, Lee, Kent. Eng. Pat. 7687, April 1, 1913.

Press-cakes of undecorticated cotton seed, are ground and then separated into meal, husks, and cotton fibre, *e.g.*, by a blast of air. The meal is used as a food either alone or mixed with other foodstuff. The husks may be ground and added to other foods such as a mixture of molasses and peat: or the husks and cotton fibre, mixed, if desired, with sphagnum, are digested unde pressure, with or without addition of a small quantity a suitable acid, the sugar and easily digestible fibre thu obtained serving as a food or food ingredient fo animals.—L. E.

XIXb.—WATER PURIFICATION; SANITATION.

[*Water.*] *Storage; Advantages and disadvantages of reservoir* ——. W. P. Mason. J. Franklin Inst., 1914, **177**, 369—384.

The main disadvantages of the storage of drinking water before distribution are the increase in colour of the lower layers of the water if the bottom of the reservoir is not clean, the growth of small organisms producing taste and smell due to an abundance of food-material extracted from the ground forming the bottom, and the deficiency in dissolved oxygen in the lower layers. An important point is the protection of the reservoir and watershed from accidental contamination by fæcal matter. The seasonal growth of algæ is easily dealt with by treatment with copper sulphate, one part of copper sulphate to 3½ million parts of water being effective, at a total cost of 14·9 cents (7½d.) per million parts of water. There is also an occasional growth of various forms of *Crenothrix*, of which *C. kuhniana* grows in water containing a large amount of organic matter, little dissolved oxygen, and about 0·3 part Fe per million. The great advantage of storage is the destruction of pathogenic and other bacteria, but care must be taken that the whole of the water undergoes the stated period of storage. A case is cited of a narrow lake 10 miles long, in which the prevailing wind blew in the direction of the flow of water down the lake; sewage matter entering on the surface at the head of the lake was carried to the lower end, where the water intake was situated, in as little as three days. Emergency water intakes, which are frequently in inferior positions, should not be used unless the water can be properly stored. —J. H. J.

Radio-activity; The measurement of the —— *of springs.* C. Engler, H. Sieveking, and A. Koenig. Chem.-Zeit., 1914, **38**, 425—427 and 446—450.

An improved form of the Engler and Sieveking fontactoscope is described, by means of which more exact measurements of the radio-activity of natural waters may be made. It consists of a vessel of ten litres capacity on the neck of which fits a hollow conical stopper, supporting a Wulf quartz-fibre electrometer. Through a hole in the stopper, which can be closed at will by a rubber plug, passes a conducting wire connecting the electroscope with a rod suspended within the large vessel. Before use the normal rate of discharge is determined by shaking in the vessel, for half a minute, one litre of inactive distilled water, charging the electroscope, and observing the fall of potential, which under normal conditions should be between 15 and 30 volts per hour. One litre of the active water is then shaken in the vessel for half a minute, whereby all but about 2 per cent. of the radium emanation is transferred to the air. The fall of potential per hour is again determined, the normal loss deducted, and a correction applied for the solubility of the emanation in the water, and for the Duane effect (size and form of the apparatus). From the fall of potential per litre per hour thus calculated, the activity of the water is given by $A=\frac{v}{300}\times\frac{c}{3600}\times 1000$ Mache units (v=fall of potential, c=capacity of system). The results to be of comparative value must be referred to some definite time from the commencement of the shaking out of the emanation, as the activity, due to the pure emanation, rapidly increases owing to the production of RaA and RaC. In making rapid measurements the readings should be taken 2 mins. from the commencement of the shaking out, and tables are given to enable such figures to be referred to the zero time, *i.e.* activity of the pure emanation.—G. F. M.

Carbon monoxide in air; Determination of ——. F. S. Sinnatt and B. J. Cramer. Analyst, 1914, **39**, 163—170.

The air, freed from carbon dioxide, unsaturated hydrocarbons and moisture, was passed through two vertical tubes packed with alternate layers of iodine pentoxide and glass wool and heated in a paraffin bath to 140°—160° C., and then bubbled through mercury and collected in a special apparatus, consisting essentially of a dry gas vessel connected with a long vertical tube dipping into mercury. The gas vessel was exhausted, connected with the vertical tube, and the gas allowed to flow in at the rate of 1 litre per hour, the volume being calculated from the fall of the mercury. The carbon dioxide formed from the carbon monoxide by the oxidising action of the iodine pentoxide could be accurately titrated in the gas vessel by Pettenkofer's process. The analyses were checked by using red-hot copper oxide in place of iodine pentoxide. —F. Shdn.

Sulphur dioxide in air; Determination of minute amounts of ——. A. Seidell and P. W. Meserve. J. Ind. Eng. Chem., 1914, **6**, 298—301.

To determine quantities of sulphur dioxide ranging from 0·0025 to 0·05 c.c. in 2½ litre samples of air (*e.g.*, from railway tunnels), 5 c.c. of a 0·1 per cent. aqueous starch paste was introduced into and distributed over the inner surface of the bottle containing the sample, and $N/1000$ iodine run in until a blue colour appears, a correction of 0·3 c.c. being made to allow for the quantity required to produce the colour in absence of sulphur dioxide. The results by this method are concordant but low, and should be multiplied by 1·3. To avoid errors due to oxidation of the sulphur dioxide by atmospheric oxygen, perfectly dry bottles should be used for collecting the samples, and except on very dry days, titration should be performed within less than half an hour.—A. S.

Soot-fall study of Pittsburgh. J. O'Connor, jun. Met. and Chem. Eng., 1914, **12**, 247.

Soot was collected in twelve different parts of Pittsburgh during one year (April, 1912, to April, 1913), the jars being changed each month. After drying in a steam oven, tar was determined by extraction with ether, the ash as usual, and the fixed carbon taken by difference: the ferric oxide in the ash was also determined. The composition of the soot at each station, and the calculated total fall, in tons per sq. mile per year, are shown in the following table:—

Composition of soot.

Station.	Tar.	Fixed carbon.	Ash.	Fe_2O_3. in ash.	Total fall.
	per cent.	per cent.	per cent.	per cent.	tons.
1	2·19	21·97	75·84	32·08	595
2	0·82	36·58	62·60	33·73	1950

Water softening; Process for the preparation of complex silica combinations with metallic or other oxides with a view to ——. P. de Brünn. Fr. Pat. 464,018, Aug. 23, 1913. Under Int. Conv., Aug. 26, 1912.

The aluminium of the aluminate-silicate compounds used for softening water by filtration, is replaced by other metals, such as tin, zinc, lead, zirconium, or the like. Examples: (1). 120 parts of zirconium oxide, 300 parts of sodium carbonate, and 500 parts of powdered silica are fused at 1400° C. and the resulting vitreous mass treated with water whilst cooling. (2). 3000 grms. of caustic soda are added to 900 grms. of a stannous chloride solution containing 21 per cent. Sn, and 500 litres of a 5—10 per cent. solution of sodium sulphate, phosphate, or chloride are added to the mixture to assist precipitation, which is effected by addition of 1500 grms. of sodium silicate. The mixture is heated, filter-pressed, dried, and hydrated, preferably with warm water.—O. R.

Water: Process and apparatus for the purification of ——. Maschinen- und Waggonbau-Fabriks Akt. Ges. vorm. H. D. Schmid and F. von Suess. Fr. Pat. 464,670, Nov. 8, 1913. Under Int. Conv., Nov. 11, 1912.

The water, before it is sterilised by the action of ultraviolet rays, is passed through a filter composed of fibrous material and then through a sand filter.—W. P. S.

Waters; Process for precipitating substances from feed —— for the prevention of incrustation in boilers. I. Belorussoff. Fr. Pat. 465,239, Jan. 31, 1913.

The feed-water is heated in a closed tank by steam from a boiler, whereby bicarbonates are decomposed and carbonates precipitated. The tank is provided with a sludge-cock and the steam pressure may be utilised for introducing further quantities of water into the tank through an injector. The treated water is conducted from the upper part of the tank to the boiler.—W. P. S.

Effluents and waste-waters from sugar factories and the like; Process of clarifying ——. T. Steen. Fr. Pat. 464,964, Nov. 15, 1913.

A series of settling tanks is employed, but instead of the effluent passing successively from one tank to the next, the tanks are filled and emptied independently. Means are provided for removing the sediment deposited in the tanks from successive charges of effluent.—W. P. S.

Wood; Sterilising ——. O. Toepfer, Magdeburg, Germany. Eng. Pat. 22,825, Oct. 9, 1913.

The wood, especially the wood of containers of butter, cakes, etc., is treated in a tightly-closed vessel having a space below for collecting condensed water, and above this space a grate, with a lower and an upper grid, for supporting the pieces of wood in a vertical position. Above the upper grid is a distributing tubular ring, provided with separate connections and valves for steam, cold water and a drying medium such as hot air, and the wood may thus be exposed in rapid succession to the action of saturated steam, cold water, a partial vacuum and a drying medium.—B. N.

Ozonising liquids; System for ——. G. F. Butler, Niagara Falls, N.Y., Assignor to American Ozone Co. U.S. Pat. 1,089,108, March 3, 1914.

The supply column of the liquid to be ozonised contains a cut-off valve and is provided with means for injecting ozone at a point between the cut-off valve and the reservoir for the ozonised liquid; a second valve, situated between the reservoir and the point of injection of ozone, and controlled by the pressure in the column, is adapted to deflect the liquid from the reservoir.—O. R.

Sterilisation of liquids [and bleaching oils, by ultra-violet rays]. V. Henri, A. Helbronner and M. von Recklinghausen. Second Addition, dated Jan. 10, 1913, to Fr. Pat. 403,945, June 11, 1909 (this J., 1910, 107).

The liquid is introduced into a rotating drum which may be slightly conical, or cylindrical and inclined. The lamp emitting the rays is mounted inside the drum and the latter may be cooled externally by a water spray and filled with an inert gas or the air may be exhausted from it. The apparatus may also be used for bleaching oils.—W. P. S.

Liquids; Centrifugal apparatus for clarifying ——. R. A. Sloan and J. E. L. Barnes. Fr. Pat. 464,525, Nov. 7, 1913. Under Int. Conv., Nov. 11, 1912.

See Eng. Pat. 25,817 of 1912; this J., 1913, 1148.—T. F. B.

Purification of gases [from suspended particles] by formation of mist by supersaturation. Ger. Pat. 270,757. *See* I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Nux vomica; Assay of ——. W. B. Cowie. Pharm. J., 1914, 38, 545.

Uniform results for the assay of *Nux vomica* can be obtained by the following method: 10 c.c. of the liquid extract are mixed with 10 c.c. of 5 per cent. acetic acid, evaporated till free from alcohol and cooled to 15° C. The liquid is mixed with 5—10 c.c. of *liquor ferri chloroxidi* and made up to 50 c.c. After shaking well, 25 c.c. are filtered off, mixed with a solution of 2·5 grms. of sodium carbonate crystals in 12·5 c.c. of water, extracted three times with 10 c.c. of chloroform, which is distilled off and the residue weighed after drying at 100° C., the weight being taken as total alkaloids. The residue is dissolved in excess of $N/10$ sulphuric acid and titrated with $N/10$ sodium hydroxide, using cochineal as indicator. The solution is evaporated, mixed with 4 c.c. of dilute sulphuric acid and made up to 12·5 c.c. This is heated to 25° C. for 20 minutes with 1·5 c.c. of nitric acid of sp. gr. 1·375. The liquid is then made alkaline with 10 per cent. sodium hydroxide solution, shaken out three times with 10 c.c. of chloroform, which is evaporated and the residue dried at 100° C. before weighing.—F. Shdn.

Carica Papaya juice; Standardisation of dried ——. F. F. Shelley. Analyst, 1914, 39, 170.

The following is a modification of Sörensen's test (compare this J., 1908, 135): 4·0 grms. of casein are dissolved in 100 c.c. of an alkaline solution containing 4 c.c. of $N/1$ soda. 25 c.c. of water containing 0·1 grm. of dried *Papaya* juice are added to 25 c.c. of the casein solution and the whole kept at 37° C. for 4 hours. 10 c.c. of a neutralised 40 per cent. formaldehyde solution are added to 20 c.c. of the liquid, and the mixture, equivalent to 0·04 grm. of the dried juice, is titrated with $N/5$ soda, using phenolphthalein as indicator. A similar mixture is made without the *Papaya* juice and titrated. The difference, which should be at least 1 c.c., gives the amount of acid required to neutralise the amino-acids formed by the hydrolysis of the casein. Pure dried *Carica Papaya* juice should give no reaction for starch with iodine, nor reduce Fehling's solution before or after hydrolysis.—F. Shdn.

Liquorice powder; Composition and analysis of compound ——. A. E. Parkes and F. Major. Analyst, 1914, 39, 160—162.

Moisture and ash are estimated by the usual methods. The carbon bisulphide extract is obtained by exhausting 5 grms. with the dry solvent for 12 hours in a Soxhlet apparatus, and after weighing, the extract is oxidised with fuming nitric acid preparatory to precipitation with barium chloride for determining the sulphur. The difference between the sulphur and total extract is principally oil from the fennel. The dry extracted powder is mixed with water, made up to 250 c.c. and allowed to digest with occasional shaking for 12 hours. After settling, 50 c.c. of the filtered liquid are evaporated to obtain the aqueous extract. Sugar can be determined in another 50 c.c. of the filtrate by the usual methods after treatment with lead acetate solution. The amount of crude glycyrrhizin is determined by acidifying 50 or 100 c.c. of the aqueous filtrate with dilute sulphuric acid, filtering off the precipitate and washing with a little cold water. The precipitate is dissolved in dilute ammonia, the solution filtered, evaporated to dryness and weighed. When senna is present, the ammoniacal solution has a fine cherry-red colour. The total sulphur is determined by oxidising about 1 grm. of the powder with fuming nitric acid and a little potassium nitrate or chlorate. This should be determined, as the sublimed sulphur used in making up the powder may not be completely soluble in carbon bisulphide. A microscopical examination should also be made. The extreme figures for 13 samples obtained on the market were: loss at 100° C. 7·9 to 3·0; ash 6·2 to 4·6; carbon bisulphide extract 10·7 to 9·2; sulphur in extract 7·9 to 6·3; total sulphur 9·2 to 7·8; cold water extract 63·9 to 61·1; ash of extract 2·4 to 1·8; sucrose 50·3 to 48·3; crude glycyrrhizin 2·9 to 1·2 per cent.

—F. Shdn.

Saffron; Examination of ——. R. Krzizan. Z. öffentl. Chem., 1914, 20, 109—114, 121—124.

Low results are obtained in the determination of invert sugar in saffron when sodium sulphate is used to remove the excess of basic lead acetate used for clarification; from 3 to 4 per cent. more invert sugar is obtained when the excess of lead is precipitated by sodium phosphate. Experiments with pure sucrose and with honey showed that correct results are obtained with sodium phosphate. Certain genuine samples of saffron contained as much as 21·75 per cent. of invert sugar and, after inversion, 23·53 per cent., calculated on the dry substance. The accepted maximum of 20 per cent. of invert sugar for pure saffron is, therefore, somewhat too low. Genuine saffron frequently contains up to 1 per cent. of sand, and usually yields not more than 6 per cent. of ash; about 70 per cent. of the ash is soluble in water and the alkalinity of the soluble ash corresponds with 6·9 c.c. of $N/1$ acid per grm. of total ash.—W. P. S.

Saffron; Detection of magnesium sulphate in ——. A. Nestler. Z. Unters. Nahr. Genussm., 1914, 27, 388—391.

The addition of glycerol to a saturated solution of magnesium sulphate prevents the latter from crystallising, but if a drop of chloral hydrate solution (5 : 2) be added, crystals of magnesium sulphate form almost immediately. To detect magnesium sulphate in saffron, the filtered aqueous solution is allowed to evaporate at the ordinary temperature to a syrup, and a drop of this is mixed on a microscope slide with a drop of chloral hydrate solution. In the presence of magnesium sulphate, crystals are obtained either at once or after the lapse of a few minutes. The crystals may be washed with alcohol and then identified by means of microchemical tests.—W. P. S.

Extraction by means of immiscible solvents; A study of the methods for —— *from the point of view of the distribution coefficients. I.* J. W. Marden. J. Ind. Eng. Chem., 1914, 6, 315—320.

The distribution ratio (d=concentration in water: concentration in immiscible solvent) was determined for a number of cases met with in analytical practice, and from the values obtained the efficiency of extraction was calculated by the formula: $x_n = x_0 \left(\frac{da}{e+da} \right)^n$, where a=volume of aqueous solution, e=volume of immiscible solvent, x_0=initial concentration of aqueous solution, and x_n= concentration after n extractions; the calculated results were checked by experiments. From the results obtained improvements in certain analytical methods are suggested. *Acetanilide in hydrogen peroxide.* Washing 50 c.c. of the sample twice with 20 c.c. of ether and once with 20 c.c. of chloroform (Bull. 150, U.S. Bureau of Chemistry) extracts only 95 per cent. of the acetanilide. Using chloroform only, in 10 c.c. portions, five washings (2 mins. each) will extract 99 per cent. and 8 washings 99·9 per cent. of the acetanilide. *Acetanilide, vanillin, and coumarin in vanilla extracts* (Hess and Prescott, this J., 1899, 397, 525; Winton and Silverman, this J., 1902, 1300). Extraction of 50 c.c. of the extract, freed from alcohol, once with 20 c.c. and 3 times with 15 c.c. of ether extracts 99·5—99·6 per cent. of the vanillin and practically all of the coumarin, but only 93 per cent. of the acetanilide. For removing the vanillin from the ether solution, the original proposal of Hess and Prescott appears to be the best: shaking 50 c.c. of the ether solution once with 10 c.c. of 5 per cent. ammonia removes practically all the vanillin and only about 5 per cent. of the acetanilide and 3 per cent. of the coumarin. *Salicylic acid, benzoic acid, and β-naphthol.* Salicylic and benzoic acids are removed practically completely from aqueous solution by a few extractions with ether, and β-naphthol in like manner from a slightly acid solution by a few extractions with chloroform. *Saccharin.* Chloroform is not so good and amyl acetate is slightly better than ether for extracting saccharin from aqueous solutions. The results are influenced considerably by the concentration of hydrochloric acid in the aqueous layer. It is recommended that 50 c.c. of the aqueous solution be treated with 2·5 c.c. of 38 per cent. hydrochloric acid and shaken four times with 10 c.c. of ether (2 mins. each time), whereby 99 per cent. of the saccharin is extracted; six washings give an extraction of 99·9 per cent. *Caffeine and tannin.* In the separation of caffeine from tannin in the analysis of tea, less chloroform may be used than recommended by Smith (this J., 1913, 804). Four washings of 50 c.c. of the solution with 10 c.c. portions of chloroform will extract 99·7 per cent. and five washings 99·95 per cent. of the caffeine.

—A. S.

Chrysophanic acid; Some reactions of —— *with reference to its detection in complex medicinal preparations.* E. M. Bailey. J. Ind. Eng. Chem., 1914, 6, 320—321.

Chrysophanic acid, a dihydroxymethylanthraquinone, $C_{15}H_{10}O_4$, is a yellow colouring principle present in certain medicinal plants, notably senna and rhubarb. For its detection in complex medicinal preparations an alcoholic extract of the sample is freed from alcohol or diluted with water, then acidified with a few drops of hydrochloric acid, and extracted with ether (if an emulsion forms it is easily destroyed by adding acetone). The ethereal solution is shaken with 2½ per cent. ammonia solution: chrysophanic acid, phenolphthalein, curcumin, and hæmatoxylin all impart a red colour to the alkaline solution. The solution is acidified and shaken with ether, which extracts only the chrysophanic acid and phenolphthalein. A portion of the ethereal solution is boiled with 4—5 c.c. of 25 per cent. sodium hydroxide solution and a little zinc dust: chrysophanic acid and phenolphthalein are both reduced, but on diluting the alkaline solution and treating with a few drops of hydrogen peroxide, only the chrysophanic acid is re-formed by oxidation, and its presence is indicated by a characteristic cherry-red colouration.—A. S.

Manganous oxide; Use of —— *for the catalysis of acids. Preparation of aldehydes and pentamethylenic ketones. Formation of cyclopentylamines.* P. Sabatier and A. Mailhe. Comptes rend., 1914, 158, 985—991.

Manganous oxide, prepared by heating the carbonate, when heated to 350° C., is an excellent catalyst for the reduction of organic acids by formic acid. If the vapour of the acid together with excess of formic acid vapour is passed over the heated oxide, a good yield of the corresponding aldehyde is obtained. *e.g.* isovaleric acid gives a 50 per cent. yield of isovaleraldehyde. If adipic acid or its β-methyl derivative is used in the absence of formic acid, the vapours being carried over the catalyst by a current of carbon dioxide, cyclopentanone or β-methylcyclopentanone can easily be obtained with about 80 per cent. yields. The oximes of these ketones on being reduced by hydrogen in contact with metallic nickel at 180° C., are converted into the corresponding amines, primary, secondary, and tertiary amines being formed in each case. The secondary amine is obtained in greatest quantity (upwards of 50 per cent.), the remainder containing primary and tertiary in equal quantities.—W. H. P.

Barbier-Grignard reactions ; (1) *Some* ——. (2) *Processes for the preparation of unsaturated hydrocarbons with conjugated double linkages* [*isoprene*]. L. P. Kyriakides. J. Amer. Chem. Soc., 1914, **36**, 657—670.

(1) With aliphatic ketones and aldehydes, the best results were obtained by working at a low temperature and with vigorous shaking, especially in the case of substances containing mobile halogen atoms. In some cases, ethyl chloride was used with advantage, instead of the bromide, in preparing the Grignard reagent, the addition product with magnesium-ethyl chloride and chloroacetone, for example, in the preparation of chloromethylbutanol, being much more soluble in ether than the ethyl bromide addition product. (2) Oxides of the hydrocarbons were dehydrated to hydrocarbons of the butadiene series by heating at temperatures above 350° C., in the presence of catalysts (*e.g.*, kaolin) ; a reduced pressure was found necessary. Using a high vacuum, the hydrocarbons obtained could be polymerised directly after distillation. 1-Methylbutanal (methylethylacetaldehyde) was dehydrated in a similar manner to isoprene, but a purer product, readily polymerising to caoutchouc, was obtained by direct dehydration of 2-methyl-1.2-butylene oxide, prepared from chloromethylbutanol.—F. Sodn.

Saturated and unsaturated hydrocarbons ; Simultaneous oxidation of —— *by potassium permanganate.* N. Kishner. J. Russ. Phys. Chem. Ges., 1913, **45**, 1788—1792. Chem. Zentr., 1914, **1**, 1498.

In experiments on the separation of mixtures of saturated and unsaturated hydrocarbons by oxidising the latter with permanganate, it was observed that saturated hydrocarbons though quite resistant to the action of permanganate when pure, were oxidised to a considerable extent in presence of unsaturated hydrocarbons. 2.6-Dimethyloctane, for example, was not attacked when boiled with permanganate solution alone, but in presence of menthene, was oxidised to the extent of up to 50 per cent.—A. S.

Formaldehyde, its applications and analysis. G. Desmurs. Bull. Assoc. Chim. Sucr., 1914, **31**, 660—674.

An account is given of the properties, industrial applications, and methods of analysis of formaldehyde, and a short bibliography is appended (see Romijn, this J., 1897, 366 ; Nicloux, this J., 1897, 941 ; Blank and Finkenbeiner, this J., 1899, 79 ; Clowes and Tollens, this J., 1900, 77 ; Peska, this J., 1901, 1031 ; Vanino and others, this J., 1901, 1251 ; 1902, 193 ; 1913, 83 : Hartwagner, this J., 1913, 111). The following modification of Romijn's iodometric method, is recommended for the analysis of commercial formaldehyde :—The sample is diluted until it contains about 2 per cent. of formaldehyde, and 5 c.c. are mixed with 30 c.c. of $N/1$ sodium hydroxide, and treated with $N/5$ iodine, whilst agitating, until the liquid is bright yellow. The flask is then closed, and shaken for 1 min., 40 c.c. of $N/1$-hydrochloric acid are added, and the excess of iodine is titrated with sodium thiosulphate solution. One c.c. of $N/1$ iodine corresponds to 0·015 grm. of formaldehyde.—J. H. L.

Patents.

Organic solvents ; Production of ——. E. C. R. Marks, London. From E. I. du Pont de Nemours Powder Co., Wilmington, Del., U.S.A. Eng. Pat. 29,963, Dec. 30, 1912.

A mixture containing halogen derivatives of more than one hydrocarbon of the paraffin series is acetylated. For example, the fraction of petroleum spirit of boiling point 28° to 69° C. is chlorinated, and the mixture of chloropentanes and chlorohexanes is acetylated ; the product consists of a mixture, in approximately the proportions given, of the following :—Olefines, 35 per cent. ; chloroolefines, 5 per cent. ; acetic esters of monohydric alcohols, 50 per cent. ; acetic esters of dihydric alcohols, 10 per cent. If desired the mixture may be separated by fractionation, and the various products used as solvents, or the undistilled mixture may be used as a solvent, particularly for nitrocellulose.—T. F. B.

Liquid [*methyl acetate*] *which is able to dissolve energetically various substances ; Process for making a* ——. A. Helbronner and G. E. Criquebeuf. Fr. Pat. 464,646, Jan. 18, 1913.

A liquid containing from 65 to 75 per cent. of methyl acetate, the remainder being chiefly acetone and methyl alcohol, is obtained by distilling crude or purified pyroligneous acid until about one-tenth of the volume has passed over, adding to the residue a suitable esterifying agent (*e.g.*, 2 to 3 per cent. of a mineral acid), and continuing the distillation until about one-third of the residue has distilled ; the combined distillates are finally rectified. The product may be used for dissolving resins, fatty compounds, cellulose nitrate or other cellulose esters, etc.—T. F. B.

Therapeutical agent suitable for the treatment of tuberculosis ; Manufacture of a ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 2610, Jan. 31, 1914.

A remedy for tuberculosis is obtained by cultivating tubercle bacilli on nutrient broth containing a small quantity of a gold salt, but insufficient to prevent entirely the development of the bacilli ; the culture is then transferred to a nutrient medium containing a larger quantity of gold, and the process is repeated several times, on media containing increasing quantities of gold salt. The final product consists of tubercle bacilli which contain a certain amount of gold, and which are not killed by gold salts ; it can be made into emulsions with glycerin water or converted into tuberculin by the usual methods.—T. F. B.

Arseno-metal preparations and process of making sam P. Ehrlich, Frankfort, B. Reuter, Höchst, and P Karrer, Frankfort, Assignors to Farbwerke vorm Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,091,881, March 31, 1914.

Arseno-compounds containing the radical, $C_6H_5.As : As$ are combined with salts of heavy metals in solution. I particular, the hydrochloride of 3.3′-diamino-4.4′-d hydroxyarsenobenzene is combined with cuprous chlorid —T. F. B.

Azo dyestuffs containing the arseno group ; Process f making ——. Farbwerke vorm. Meister, Lucius, un Brüning. Ger. Pat. 271,271, Feb. 19, 1913.

Azo dyestuffs which contain the arseno group, and a suitable for therapeutic purposes, are obtained by reduci with hypophosphorous acid azo dyestuffs containing arsinic acid or arsenoxide grouping. The azo group is n affected by the reducing agent.—T. F. B.

Fatty acids containing arsenic and phosphorus ; Process for preparing [iron] salts of ——. F. Heinemann. Ger. Pat. 271,158, Jan. 3, 1913. Addition to Ger. Pat. 257,641.

The higher unsaturated fatty acids containing arsenic and phosphorus described in the principal patent (see Eng. Pat. 18,732 of 1912 ; this J., 1913, 109) are converted into their iron salts. The products are suitable for use in medicine, especially for the treatment of chlorosis and anæmia. (See also Eng. Pat. 10,378 of 1913: this J., 1914, 218.)—T. F. B.

Cyclic chlora compounds ; Process for obtaining ——. Fabriques de Produits de Chimie Organique de Laire. Fr. Pat. 464,645, Jan. 17, 1913.

Benzyl chloride and its homologues are obtained by condensing aromatic hydrocarbons with monochloro-acetone in presence of stannic chloride or other suitable metallic chloride. When homologues of benzene are used, the chloromethyl group generally enters the benzene nucleus in the *p*-position to the alkyl group. The ethyl, propyl, butyl, amyl, cyclohexyl, methylethyl, methylpropyl, and methylbutyl derivatives of benzyl chloride have been prepared in this way. The following example illustrates the process :—Equimolecular proportions of toluene and chloro-acetone are dissolved in twice their weight of carbon bisulphide or carbon tetrachloride, the solution is cooled to about —10° C., and ¼ mol. of stannic chloride is added drop by drop. After the mixture has stood for half an hour the oily layer is separated, poured on ice, washed with water, and distilled ; the unchanged toluene passes over first and then, at 102°—110° C., under a pressure of 30 mm., the *p*-methylbenzyl chloride, the yield being about 60 per cent. of the toluene used.—T. F. B.

Phenyl αβ-dibromopropionic acid ethyl ester ; Process for preparing stable ——. E. Merck. Ger. Pat. 271,434, Dec. 8, 1912.

Ethyl cinnamate is brominated in presence of an indifferent solvent in which the dibromo ester is soluble with difficulty (*e.g.*, petroleum spirit, carbon tetrachloride, and chloro derivatives of ethane), and the product is treated with water. The resulting phenyl-αβ-dibromopropionic acid ethyl ester (ethyl αβ-dibromohydrocinnamate) is stable, especially if the presence of iron or its compounds, or other substance which favour its decomposition, is avoided during its preparation.—T. F. B.

Calcium lactate ; Process for preparing an acid ——. Chem. Werke vorm. Dr. H. Byk. Ger. Pat. 271,643, Sept. 6, 1912.

The acid calcium lactate containing four mols. of lactic acid is treated with a solvent for lactic acid ; or calcium oxide, hydroxide, carbonate, or lactate, is evaporated with a solution containing a quantity of lactic acid corresponding to about three mols. for each atom of calcium, any excess of lactic acid being removed by a solvent. The resulting acid lactate forms stable mixtures with carbonates and bicarbonates, and so can be used in the preparation of baking powders.—T. F. B.

Hydrastinine ; Manufacture of ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld. Germany. Eng. Pat. 14,120, June 18, 1913.

See Ger. Pat. 267,272 of 1913 ; this J., 1914, 220.—T. F. B.

Per-acids from aldehydes ; Process for the manufacture of ——. Consortium f. Elektrochem. Industrie G. m. b. H. Nuremberg, Germany. Eng. Pats. 16,849 and 17,018, July 22 and 24, 1913. Under Int. Conv., Sept. 6, 1912, and April 11, 1913.

See Fr. Pat. 460,972 of 1913 ; this J., 1914, 42.—T. F. B.

Azo dyestuffs containing the arseno-group ; Manufacture of ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 2090, Jan. 26, 1914.

See Ger. Pat. 271,271 of 1913 ; preceding.—T. F. B.

Quinoline-4-carboxylic acids arylated in the 2-position ; Sulpho compounds of ——. A. Thiele, Assignor to Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. U.S. Pat. 1,091,870, March 31, 1914.

See Eng. Pat. 16,482 of 1913 ; this J., 1914, 42.—T. F. B.

Formaldehyde ; Process for making crystalline polymerisation products from ——. F. Pollak. Fr. Pat. 461,731, Nov. 10, 1913. Under Int. Conv., Dec. 13, 1912.

See Eng. Pat. 25,830 of 1913 ; this J., 1914, 218.—T. F. B

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patents.

Colour photography and colour cinematography. F. W. Donisthorpe, Barnes. Eng Pat. 7368, March 28, 1913.

A negative taken through a light filter of one colour is superimposed on a positive transparency made through a filter of another colour, and a print is made through both, so that only the coloured portions of the image appear in the resulting print ; this is then coloured with a suitable toning bath and superimposed with a black and white print. The silver image may be toned with a bath which so affects the gelatin combined with the silver that the subsequent staining baths have no effect on that part of the gelatin For example, baths containing iron and vanadium or uranium may be used to produce red or yellow images, and the toned prints may be stained with green or violet dyes.—T. F. B.

Photography in colours on fabrics ; Process of ——. T. Valette and R. Feret. First Addition, dated Oct. 4, 1913, to Fr. Pat. 457,446, May 3, 1913.

An apparatus is described for holding the support to ensure perfect register of the monochrome images, for use in the process of the principal patent (see this J., 1913, 1033).—T. F. B.

Toning bath containing tellurium for photographic silver images. Chem. Fabr. auf Actien vorm. E. Schering. Ger. Pat. 271,041, Dec. 17, 1912.

A solution of tellurium in an alkali sulphide is used for toning photographic silver images. The tones obtained are somewhat bluer than those produced by selenium (see U.S. Pat. 1,064,379 ; this J., 1913, 712), and resemble those obtained with gold toning baths.—T. F. B.

XXII.—EXPLOSIVES ; MATCHES.

Viscosity of solutions of nitrocellulose in alcoholic camphor solutions. Nishida. See V.

Patents.

Cordite mill. A. A. Schaschke, Aberdeen. Eng. Pat. 15,605, July 7, 1913.

The teeth of a row of discs, spaced upon a rotating or rocking shaft, pass between the teeth of a fixed comb.

The cordite is carried forward by the moving teeth, and sheared between them and the fixed teeth.—O. E. M.

Matches; Process of making a composition for use in ——. H. Staier, New York. U.S. Pat. 1,092,408, April 7, 1914.

A SUBSTITUTE for yellow phosphorus is produced by heating a mixture of six parts by weight of red phosphorus, two of metallic sulphide, and three of sulphur to about 500° F. (260° C.) washing, and drying.—O. E. M.

Explosive. O. Silberrad, Buckhurst Hill. U.S. Pat. 1,092,758, April 7, 1914.

SEE Eng. Pats. 13,861 of 1911 and 712 of 1912; this J., 1912, 978.—T. F. B.

XXIII.—ANALYTICAL PROCESSES.

Lead; Determination of small quantities of ——. M. Siegfried and W. Pozzi. Biochem. Zeits., 1914, **61**, 149—156.

MINUTE quantities (less than 1 mgrm.) of lead can be rapidly determined, in tap water, for example, by the following modification of the colorimetric method. 100 c.c. of the liquid are mixed with 9 c.c. of *N*/100 hydrochloric acid, 1 c.c. of a 1 per cent. solution of the purest gum arabic, and 10 c.c. of a saturated solution of hydrogen sulphide. From the tint of the liquid the quantity of lead present is estimated approximately, and a standard solution for colorimetric compari on is made by diluting the requisite volume of lead nitrate solution (0·1599 grm. per litre) to 100 c.c., and mixing this with acid, gum arabic and hydrogen sulphide, as before. Details of procedure are given from the comparison of the liquids in a Duboscq colorimeter. Small quantities of iron and manganese do not affect the results. The concentration of acid employed prevents the precipitation of iron sulphide but does not interfere with the complete conversion of the lead into sulphide. The gum arabic is employed to prevent flocculation of the lead sulphide. When lead compounds are evaporated with nitric acid, *e.g.*, in the investigation of organic material for lead, a small quantity of the latter is converted into an insoluble form (possibly silicate). —J. H. L.

Arsenic; Quantitative separation of —— from metals by means of hypophosphorous acid. L. Brandt. Chem.-Zeit., 1914, **38**, 461—463, 474.

FROM almost all the common metals, even when associated with a relatively large excess, arsenic can be quantitatively separated by precipitation with hypophosphorous acid, and determined iodometrically in the precipitate by the method already described (this J., 1914, 28). Iron, manganese, nickel, cobalt, zinc, chromium, aluminium, tin, sodium, potassium, and the alkaline-earth metals have no influence on the accuracy of the arsenic determination, and the metals themselves can be subsequently determined by the usual methods. Lead and silver should be removed as sulphate and chloride respectively before addition of hypophosphorous acid. Copper, if only present in small amount, does not interfere, but if present in large proportion, the arsenic should be precipitated first as ferric arsenate, the precipitate dissolved in hydrochloric acid and the solution then treated with hypophosphorous acid in the usual way. Mercury must likewise be previously removed as mercurous chloride, by reduction with cold formic and phosphorous acids or with a boiling ammoniacal solution of hydrazine sulphate. Bismuth, though sometimes precipitated with the arsenic, can be readily redissolved in the excess of concentrated hydrochloric acid present. Antimony cannot be separated from arsenic by this method.—G. F. M.

XXIV.—MISCELLANEOUS ABSTRACTS.

"*Negative*" *adsorption.* A. M. Williams Faraday Soc., April 22, 1914. [Advance proof.]

An experimental examination of the adsorptive action of purified blood charcoal on aqueous solutions of various electrolytes. With very dilute solutions of potassium chloride or magnesium sulphate the adsorption was positive; on increasing the concentration the adsorption rose to a maximum, then declined, and finally attained a negative value. A similar maximum was observed for ammonium chloride, but in this case no negative value was reached. Barium chloride solution showed an uninterrupted increase over the range of concentrations investigated.—J. R.

Book Received.

E. Merck's Annual Report (of Recent Advances in Pharmaceutical Chemistry and Therapeutics). 1912. Volume XXVI. E. Merck, Darmstadt. London: 66, Crutched Friars, E.C. 1913. Price 1s. 6d.

Volume (8¾ by 5¾ ins.) containing 473 pages of subject-matter, and alphabetical indexes of subjects, of diseases, etc., of authors, and an alphabetical bibliographic index. There is at the commencement a monograph on lecithin (50 pages), with an index to the literature of lecithin (22 pages), and at the end an article on the "Assay and Standardisation of Digitalis preparations," by Prof. H. Heintz of Erlangen.

PROF. R. F. RUTTAN IN THE CHAIR.

MAPLE SAP PRODUCTS AND THE CANADIAN STANDARDS.

BY PROF. J. F. SNELL.

Introduction.

The making of maple syrup and sugar is an industry confined to the area of about one-eighth of the continent of North America. Only in the eastern provinces of Canada and the north-eastern quarter of the United States does the sugar maple occur in sufficient abundance to render the industry possible.

Manitoba, Minnesota, Iowa, and Missouri mark the western limits, and Tennessee, Kentucky, and Virginia the southern limits of the productive territory. Ontario and Quebec, the northern New England States, New York, Pennsylvania, Ohio, Indiana, Michigan, Wisconsin, and West Virginia are the only communities in which the industry is carried on upon a considerable scale. The maple sugar industry is thus a much more localized one than either the cane-sugar or the beet sugar industry. It makes no attempt to compete with these latter in the production of white sugar. From the standpoint of these larger sugar industries maple products are crude, but their value as luxuries depends upon this very fact, the characteristic maple flavour enhancing their price, wherever that flavour is in demand.

In the regions where the sugar maple flourishes the industry is an old-established branch of farming. In spite of claims to the contrary there appears to be good evidence that the aborigines made sugar before the coming of the white man. Some historians have been disposed to credit Michel Sarrazin, a Quebec physician who lived from 1659 to 1734, with the discovery of the art of making syrup and sugar from maple sap, the alleged discovery being dated about 1695. Sarrazin enjoyed the distinction of correspondent of the Académie Royale des Sciences and in 1730 communicated to that body a memoir containing some accurate references to the sugar maple and its products.

But Père Lafitau, writing just five years after the reputed discovery, describes and gives a picture of an Indian sugaring and explicitly states that the French work it better than the Indians, "*from whom the former have learned to make it.*" There are also earlier references to the making of maple syrup and sugar. One of the earliest and most interesting, though not the most definite, is that of Robert Boyle in 1663, which is worth quoting for its quaint language:

"There is in some parts of New England a kind of tree, whose juice that weeps out of its incisions, if it be permitted to exhale away the excess moisture, congeals into a sweet substance."

In 1675 the missionary Le Clerq writes concerning maple sap: "What seemed to me so remarkable in this maple water is that if by boiling one reduces it to one-third its volume (one-thirtieth would be more accurate) it becomes a real syrup, which hardens much like sugar and takes a reddish colour. Little loaves of it are made and sent to France and it is often used when French sugar is not to be had."

Joutel in 1684, La Hontan in the same year, and Père Rasles in 1689 also describe the making of syrup and sugar.

What is, if correct, a most convincing piece of evidence in favour of the Indian as the original sugar maker, is presented by Sy in his discussion of the question.[*] He states that although there are in the Indian languages many names for maple tree and maple sugar, only a single one has been found that shows any likeness to any European word for sugar, namely the Cree word *so-kaw*, which is believed to be a corruption of the French *sucre*. That this word was applied only to the white sugar introduced by the French serves to add force to the argument that if the Indians had learned the art of making maple sugar from the white men, they would inevitably have adopted some of the European words relating to it. Sy also states that some tribes designated a certain month of the year the "sugar moon," and held a sugar festival or "maple dance" in the spring, when old and new sugar were mingled by the medicine man, as he invoked the aid of the Great Spirit.

The Maple Tree.

Syrup and sugar are made from several species of maple. The hard, rock or sugar maple—*Acer saccharum*—occupies the first place. A variety of this species, known as the black maple—*Acer saccharum nigrum*—is equally good but is rare in Canada. The soft or silver maple—*Acer saccharinum*—and the red maple—*Acer rubrum*—are also tapped, especially in districts where the sugar maple is not abundant. The sap of the latter two varieties contains less sugar than that of *Acer saccharum* and their barks contain pigments which discolour the sap.

The usefulness of the sugar maple tree is by no means confined to its annual production of sugar. Its wood is one of the most valuable of our hardwoods. Tough, heavy, strong, and very hard, it is capable of taking a high polish and wears very evenly. Hard maple is widely used as frame-wood in agricultural machinery, as axles of waggons and as keel wood for ships. It makes excellent flooring and is considered the best wood in the market for the manufacture of wooden bowls and shoe-lasts. The "curly" and "bird's-eye" modifications and the rarer "blister" or "landscape" wood, are among the most beautiful of veneer woods used in the manufacture of household furniture and the panelling of railway carriages. Other uses of hard maple are for waggon spokes, saddle-trees, shoe-pegs and tooth-picks. The wood that is not suitable for these higher applications can be used for fuel—hard maple being the very best of our Canadian stove woods—or for the manufacture of charcoal, wood alcohol, and acetic acid. Mr. R. H. Campbell, Director of Forestry for the Dominion Government, has given it as his opinion that it would, in the end, prove a more profitable investment to plant sugar maples than white pines, though the maple seedlings are dearer and the rate of growth much less than that of the pines. The advantage of the maple over the pine would be found more particularly in the case of the small woodlot owner or farmer, who has many uses for the wood, as well as for the sap, and especially in those regions where the sugar maple already exists in the stand.[†] It must be admitted, however, that the conditions of growth favourable to maximum lumber production are not those most favourable to maximum sap production. The former demands a long, unbranching stem; the latter a spreading crown with an extensive leaf area. The moist, humus-rich soil of the forest is favourable to both sap and wood production. The maple, therefore, thrives best in groves, rather than in the open.

The sap.

The primitive method of tapping was to gash the tree with an axe. The modern method is to bore one or more holes one or two inches deep, with a $\frac{3}{8}$ to $\frac{1}{2}$ in. bit. Into the hole is driven a metal spout, which usually carried a hook upon which a bucket is hung to catch the dropping sap. That the flow of the sap is caused by an internal pressure has been established, but the nature of this pressure has not been made clear. Experience shows that the best runs of sap are obtained on moderately warm calm days, following frosty nights. Sap will flow in such weather at any time of the winter, but it is only in the early spring that such weather is at all frequent.

---

[*] Journal of the Franklin Inst., Oct. 1908.

[†] Spencer, The Maple Sugar Industry in Canada. Dominion of Canada Department of Agriculture, Bulletin No. 2b, 1913, pp. 19—20.

The Indian drew his maple sap through wooden spouts, collected it in wooden troughs and probably boiled it in wooden or earthen vessels by throwing in heated stones. Wooden spouts, buckets and gathering and storage tanks are not yet entirely discarded, but the up-to-date sugar maker uses no vessels but those of heavily tinned iron. Experience has shown that the sap keeps better in metal vessels of this kind and the bacteriological investigations of the Vermont Experiment Station have made clear the reason.

Maple sap is a dilute aqueous solution of sucrose, salts and albumin. Such a solution constitutes an ideal culture solution for micro-organisms and the sap is subject to nearly as many and as diverse diseases as is milk. Drawn from the tree and stored under aseptic conditions maple sap will keep perfectly for years, even with free access of air. But in practice it becomes more or less infected with bacteria and moulds and deteriorates rapidly, in such a manner that the best grade of syrup can only be made by boiling the sap the day it is drawn from the tree or at latest the following morning. The most common forms of organisms present in maple sap, it appears, are the fluorescent bacteria and these affect the colour rather than the flavour of the sap. The non-fluorescent spore-bearing bacteria and the moulds do not seriously darken the colour but injure the flavour and in many instances render the sap turbid. Certain specific organisms, believed to be new species, render sap stringy and affect the flavour and clearness like the moulds and non-fluorescent bacteria. Sap affected by any of these diseases is popularly termed "sour," although its acidity is, as a rule, not more than normal.

It has long been realised that high-grade syrup cannot be made from the sap obtained towards the end of the sugar season. "Last run" goods are often very dark in colour and usually lack the delicate flavour possessed by the best syrups. Green sap is almost always secured just before the close of the season when the leaf buds are ready to open. The term "buddy" is commonly applied to the flavour of this late run sap. The work of the bacteriologists has shown that, while there is undoubtedly a deterioration in the flavour of sap due to physiological changes occurring in the tree towards the end of the season, much of the trouble which has been designated "buddiness" is really due to the growth of micro-organisms, which naturally becomes more rapid towards the end of the season, when the weather is warmer. The advantage of metal vessels over wooden is, therefore, due to the superior cleanliness of the former. Covers on the buckets also make for cleanliness.

Modern "gathering tanks" for conveying the sap to the sugar-house are of galvanised or tinned iron, as are also the storage tanks from which the sap is run into the evaporators. In the best practice these storage tanks are in a covered shed on the north side of the sugar-house, so that the sap is kept cold while in storage. In warm weather ice is kept in the sap in the storage tank.

The evaporation.

An argument much relied upon by those who maintain that the Indians did not boil sap is that they could not do so for want of metal vessels. Though it is, as we have seen, probably not true that the Indians were daunted by so small a difficulty, it is certain that the advent of the iron kettle marked the first great advance in the art of sugar making. The "potash" kettle, slung over an open fire, is still in use, on not a few farms in Canada, but this primitive method of evaporation is scorned by all who aspire to make goods of any but the lowest quality.

About half a century ago it began to be realised that a wider, shallower vessel would not only be more economical of fuel but would produce a better coloured syrup. The rectangular pans then adopted have since developed into the modern evaporators of heavy tinned plate, having corrugated bottoms to increase the heating surface and divided into compartments, from one of which to another the evaporating sap flows until it finally reaches the finishing compartments, which are placed in some types at the front and in others at the back of the fire. The evaporator stands upon an iron or brick "arch," in which the fire is built. Wood fuel is almost universally employed. Rapid shallow boiling prevents caramelisation and yields a syrup of light colour and of a milder flavour than that of deep-boiled syrup.

Maple sap contains from less than two to over six per cent. of sucrose. The average is about 3 per cent. Reducing sugars are absent or present in very small quantity in fresh sap, but are developed in the yeast and mould fermentation, as well as in those produced by certain of the bacteria, through the most abundant class of bacteria, the fluorescent group, appear to have but little effect on the sucrose. In addition to sucrose, the sap contains albumin and salts, the latter apparently chiefly malates.

Maple sugar sand.

As the sap boils, the albumin coagulates and forms a surface scum, which the sugar-maker skims off. As the consistency of the liquid approaches that of a syrup a

precipitate forms known as "sugar sand" or "niter"—the latter being from the chemical standpoint a peculiarly inappropriate term, as the substance contains not more than a trace of nitrogen. A little of the precipitate settles on the bottom of the evaporator but larger quantities are obtained from the finished syrup by straining or settling.

Table I. gives the result of the analysis of six samples of sugar sand, which had been washed until the washings no longer tasted of sugar. These were all Province of Quebec samples of the season of 1911 and were analysed by Mr. Grant Lochhead in the Chemical Laboratory of Macdonald College. An analysis of Vermont sugar sand published by Warren in 1911* gives essentially the same results. The chief constituent of sugar sand is evidently calcium malate, this salt constituting from 65 to 80 per cent. of the washed material. The only other constituent of prominence is silica which in the samples analysed varied from about 6 to about 18 per cent. There is in all of these analyses a considerable proportion of undetermined matter. I understand Prof. Warren is investigating the nature of this undetermined residue.

Both Prof. Warren and Mr. Lochhead found it easy to prepare calcium bimalate from sugar sand, and malic acid can also be obtained with little difficulty. The present demand for malic acid is so small that I have found it impossible to interest Canadian manufacturers in its preparation. Through Prof. Warren's efforts, however, a German manufacturer has become interested and is now experimenting with the process on a manufacturing scale. Calcium bimalate makes an ideal acid constituent for baking powders, but it seems scarcely probable that it can be manufactured at a cost low enough to enable it to compete with cream of tartar—much less with alum and acid phosphate of lime, the acid constituents of perhaps three-fourths of the baking powder on sale in Canada at the present time.

From the results of ash determinations upon 21 samples of sugar sand received from Quebec farmers in the season of 1912, together with their reports of the amounts of sugar made by them that year, I have estimated that the sugar sand produced annually in Canada is sufficient to make 18 tons of malic acid and that produced in the United States sufficient to make 42 tons of malic acid. This would make a total possible production of 60 tons of malic acid annually. Prof. Warren has made an estimate based upon an average yield of 3000 pounds maple sugar and 20 pounds sugar sand per 1000 trees. His estimate is 175 tons of sugar sand, containing 50 per cent. of malic acid. Allowing for manufacturing losses, this would yield a quantity of malic acid not far in excess of my estimate of 60 tons. The difficulty of collecting the raw material from so large a number of producers would diminish the actually possible production of acid. On the other hand it is certain that in Canada at least, not half the maple trees are tapped each year. I have been told that many trees, growing on low ground, are left untapped because they yield so large a quantity of sugar sand that it is difficult to make syrup of good colour from their sap. If the production of sugar sand were an object, it is likely that these trees of more than average yield would be tapped and would add not a little to the quantity of material available.

Finishing syrup and sugar.

Maple syrup is not always finished in the evaporator. Many makers finish in separate finishing pans. Some finish on the cook-stove, adding milk, eggs, or soda, or combinations of these to clarify the syrup. These clarifying agents are, however, unnecessary and their use is becoming obsolete. Straining through felt gives a satisfactorily clear syrup.

There are various methods of testing the syrup to determine when the evaporation has been carried far enough. Some makers cool a sample and note its consistency. This, however, takes time, and the syrup may become over-concentrated while the test is in progress. Many take up a dipperful of the hot syrup and allow it to flow from the dipper. If it "sheets" or "forms an apron" on the dipper it is ready to draw off. Still others use a thermometer, drawing off the syrup when its boiling temperature has reached 219°—220° F. A fourth method is to use a hydrometer or saccharometer. This is graduated on the Baumé system. The hydrometer is used in a metal cylinder suspended inside the evaporator. The boiling syrup is dipped into this cylinder and gives a reading of 30·5 degrees when ready to draw off. At room temperature the density of finished syrup is 1·320 or 35·6° B.

Which of these tests gives the best results is doubtful. We are this year asking for samples of syrup finished in various ways in order to test the matter. The syrup put upon the market varies greatly in water content, much being so thin as to ferment readily and much so thick as to deposit sucrose crystals in the container. In the syrup my assistant, Mr. Scott, has examined during the past year the water-content has varied from 30 to 45 per cent. The standard of 35 per cent. water set by the Dominion Government is, I think, just right. The United States standard of 32 per cent. water is decidedly below the average actually found in syrups, and syrup with so low a water-content is unquestionably liable to crystallise in cold storage.

Maple sugar is made by evaporation of the sap beyond the syrup stage. The cooling test is much used in finishing sugar. Some makers depend upon the volume of foam produced in the boiling. Still others use the thermometer, a boiling temperature of 238°—240° F yielding a soft and one of 242°—245° F. a hard sugar. The standard of moisture content set by the Canadian Government, viz., 10 per cent., is, I think, never exceeded in hard sugar: 6·44 per cent. was the highest quantity found in a sugar by the Laboratory of the Inland Revenue Departments in its inspection of a year ago and no other sample contained over 6 per cent. of moisture.

Adulteration.

With the exception of spices there is probably no class of food materials that has been so much subjected to adulteration in Canada as maple syrup and sugar. Tables II. and III. give the results of the inspections which have been made by the Inland Revenue Department. They show in all instances a large proportion of samples adjudged adulterated or doubtful, the proportion being naturally greater in inspections made just before, than in those made immediately after, the sugaring season. Small as is the proportion of samples adjudged genuine it is by no means improbable that some of those which have met the criteria of purity applied by the Laboratory of the Inland Revenue Department were really adulterated goods. The detection of adulteration in maple products is rendered difficult by the circumstance that the adulterant commonly used is the chief constituent of maple sugar itself, viz., sucrose. Methods of analysis must, accordingly, be directed towards the determination of the minor constituents, viz., the salts and the colouring and flavouring matters.

The determination that has been most relied upon by the Laboratory of the Inland Revenue Department is one that originated in that Laboratory. If I do not mistake, it was devised by the late chief analyst, Thomas Macfarlane. It consists in adding a definite quantity of lead subacetate to the suitably diluted syrup or dissolved sugar and weighing the precipitate formed. The method was probably suggested by those previously described by Hortvet[*] and by Jones[†] in which the volume of the precipitate produced by lead subacetate was observed after sedimentation in a centrifugal machine. These methods in turn were suggested by the observation that very heavy precipitates are obtained in clarifying maple sugar solutions with lead subacetate, preliminary to polariscopic examination. The weight of the precipitate obtainable from 100 grams of the dry matter of sugar or syrup under the conditions prescribed is called the *Canadian lead number*. In addition to the Canadian lead number the Laboratory of the Inland Revenue Department has from time to time made determinations of total ash and of malic acid value. The malic acid value is determined by a method adapted by Hortvet[‡] from Leach and Lythgoe's method of determining malic acid in cider vinegar.[§] This consists in precipitating with a calcium salt and alcohol in slightly ammoniacal solution, igniting the precipitate (assumed to be calcium malate) and determining the alkalinity of the ash obtained, the results being calculated over to per cent. of malic acid in the original material.

History of the standards.

In 1911, the chief analyst and his advisory board were confronted with the task of recommending a standard of purity for maple products. Looking over the results obtained in his laboratory upon syrups collected upon the market, Dr. McGill found that only 59 samples out of 1200 had Canadian lead numbers below 2·50. His first thought was to set the standard at that figure. But after corresponding with dealers in maple products, among others with Mr. John H. Grimm, of Montreal, who advanced the objection that modern methods of evaporation tended to give syrups with lower lead values than those made in the older ways, the board settled upon a standard of 2·2 for lead value, 0·5 for total ash, and 0·4 for malic acid value. This standard was adopted by order-in-council, March 22nd, 1911, to come into effect on April 25th. The dealers continuing to raise objections to the standard, Dr. McGill invited a large number of maple syrup makers to send in samples of their products for analysis. About 450 samples were received and analysed.[||] Canadian lead value and malic acid value were determined in all of these samples. In 115 total ash was determined and also the quantity of ash insoluble in water. In 47 samples the *Winton lead number* was determined, this being a method of precipitation with lead subacetate in which the relative proportions of sugar, water and reagent are different from those used in the Canadian method, and instead of weighing the precipitate one determines the quantity of lead precipitated by analysing an aliquot of the filtrate and comparing with a blank.[*] Cognizance was also taken of the extensive work of Bryan[†] upon some 480 syrups, of which 86 were of Quebec origin. As a result of this work, the standards were altered in November, 1911, to the following, which are still in effect :—

THE PRESENT STANDARDS.

Maple sugar.

Maple sugar is the solid product resulting from the evaporation of maple sap, or of maple syrup, and contains not more than ten (10) per cent. of water. It yields not less than six-tenths (0·6) of one per cent. of ash, reckoned on the dry matter of the sugar when incinerated in such a way as to assure the earths being present as salts and not as oxides, and not less than twelve one-hundredths (0·12) of one per cent. of ash, insoluble in water, employed as described below. It yields not less than three-tenths (0·3) per cent. of malic acid, reckoned on the dry matter, when worked as described below. It yields a lead number not less than one and seven-tenths when worked by the Canadian method, nor less than one and two-tenths (1·2) when worked by the Winton method, as described below.

Maple syrup.

Maple syrup is syrup made by the evaporation of maple sap, or by the solution of maple concrete in water, and contains not more than thirty-five (35) per cent. of water. The dry substance of maple syrup shall meet all the above standards for maple sugar.

Methods of Working.

Water in maple sugar shall be determined by heating to 100° C. five (5) grammes of the finely powdered sugar, spread upon a watch glass, to constant weight. The loss of weight shall be reckoned as water.

Water in maple syrup shall be determined by drying (5) five grammes of the syrup, on asbestos fibre or in admixture with sand, to constant weight, at a temperature not exceeding 100° C. The loss of weight shall be reckoned as water.

Total ash in both maple sugar and maple syrup shall be determined by gentle ignition of five (5) grammes in platinum, to the point of incipient charring, after which, ignition to constant weight shall be completed in a muffle, at as low a temperature as possible. The resultant ash is then treated with ammonium carbonate in solution, dried and gently ignited, when the weight should remain unchanged.

Insoluble ash is determined by treating the total ash with 40 c.c. of hot water, and gently boiling for two minutes. The contents of the dish are then thrown upon a small, ashless filter, and washed with hot water till the total filtrate amounts to 100 c.c.

Malic acid.—Six and seven-tenths (6·7) grammes of the dry sugar, or its equivalent amount in syrup, is weighed into a 200 c.c. beaker and water added to make a volume of 20 c.c. The solution is made slightly alkaline with ammonia, 1 c.c. of a ten per cent. solution of calcium chloride is added, then 60 c.c. of 95 per cent. alcohol. The beaker is covered with a watch glass and heated for one half-hour on a water bath, when the flame is turned off and the beaker left to stand over night. The material in the beaker is then filtered through a good quality filter paper, the precipitate washed with hot 75 per cent. alcohol to freedom from soluble calcium salt, dried and ignited. From 15 to 20 c.c. of tenth-normal hydrochloric acid is added to the ignited residue, the lime thoroughly dissolved by careful boiling, and the excess of acid titrated with tenth-normal sodium hydroxide, using methyl orange as an indicator. One-tenth of the number of cubic centimeters of acid neutralized express the result, which for the present will be called "Malic Acid Value."

Lead Number—Canadian Method. Five (5) grammes of the dry sugar, or its equivalent in syrup, is dissolved in water, to a volume of 20 c.c. Two (2) c.c.'s of a solution of sub-acetate of lead is added, and the solutions thoroughly mixed. After standing for two hours, the precipitate is filtered off, using a Gooch crucible or a sugar tube packed with asbestos, and washed four or five times with hot water, using the suction pump, dried and weighed. The weight of the dry precipitate in grammes is multiplied by 20. The product is the Lead Subacetate Number.

Mode of preparation of solution of subacetate of lead as follows :—

Boil for half an hour 430 grammes of normal lead acetate and 130 grammes of litharge with 1,000 c.c. water. Cool the mixture, allow to settle, and dilute the supernatant liquid to 1·26 specific gravity.

Winton Method.—Twenty-five (25) grammes of dry sugar, or its equivalent in syrup, is transferred to a 100 c.c. flask with water. Add 25 c.c. of the standard lead acetate solution and shake ; fill to the mark, shake and allow to stand at least three hours before filtering. From the clear filtrate, pipette off 10 c.c. to a 250 c.c. beaker, add 40 c.c. of water and 1 c.c. of concentrated sulphuric acid ; shake and add 100 c.c. of 95 per cent. alcohol. Let stand over night, filter on a tared Gooch crucible, wash with 95 per cent. alcohol, dry in a water oven and ignite over a Bunsen burner, applying the heat gradually at first. Cool and weigh. Subtract the increase in weight of lead sulphate from the weight of the blank. Multiply the difference by the factor 27·325. The determination of the blank is made as follows :—

Transfer 25 c.c. of the standard lead acetate solution to a 100 c.c. flask, add a few drops of acetic acid and make up the whole to the mark with water. Shake and use 10 c.c. for the determination of lead, as directed in the preceding section.

Note 1.—If the maple syrup samples have undergone fermentation in any degree, the carbonic acid must be boiled off before adding the lead acetate solution. This with either of the above methods.

2. If crystallisation of sugar has taken place in maple syrup samples, this must be redissolved by gently warming the sample before proceeding with the analysis.

3. The standard lead acetate solution for Winton method is made by diluting one volume of the solution of sub-acetate of lead with four (4) volumes of water and filtering.

Criticism of the standards.

Some of the differences between these standards and those they displaced are obvious. The Canadian lead number has been lowered from 2·2 to 1·7 and the malic acid value from 0·4 to 0·3 ; and the total ash requirement has been raised from 0·5 to 0·6 per cent. The new values introduced into the standard are the Winton lead number and the insoluble ash.

The introduction of a requirement for insoluble ash was probably suggested by the work of Prof. C. H. Jones of the Vermont Agricultural Experiment station or by the Vermont State standards based upon that work.[*] It is worth noting that these latter standards are higher than the Canadian in respect to all the values common to the two. Prof. Jones's most recent statement about these standards is that they are "none too low," which seems to imply a doubt whether they are not too high.

Their requirements are : Total ash 0·77 per cent., insoluble ash 0·23 per cent., malic acid value 0·60 per cent., all, as in the Canadian standard, on the moisture-free basis. It is also worth noting that in the extensive work of Bryan the lowest percentage of insoluble ash found coincides with the figure adopted in the Vermont standard, viz. 0·23 per cent. ; but the lowest malic acid value is 0·29 per cent., thus coinciding with the Canadian standard and falling to half the value adopted in the Vermont standard.

Comparing the Canadian standard with the results obtained in the investigation upon which it was based, we find that the figure adopted for total ash is distinctly below the minimum found, viz. 0·69 per cent. The figures adopted for insoluble ash and malic acid value are identical with the minima found ; although in the former only two samples in 450 fell below 0.19, and in the latter only two samples in 450 fell below the older standard of 0·40 per cent. In setting the standards for lead value, however, the same rigid adherence to the results of the investigation was not observed. The tabulated results of the investigation show no less than twelve instances in 450 in which the Canadian lead number calculated to dry substance is below the standard adopted, and eight instances in 47 in which the Winton lead number is below the standard adopted. Why this favour to the lead number ? Is it merely an instance of parental solicitude, or are there substantial reasons for treating this value differently from the others ?

In the bulletin reporting the investigation, it is pointed out that a possible error of 0·2 in the Canadian lead value inheres in the method.[*] Thinking this might furnish an explanation of the action of the advisory board, I wrote the Chief Analyst upon this point and received from him the following reply, based upon a memorandum furnished by Mr. A. Valin :

"The reason for taking 1·7 instead of 1·2 for the minimum lead number is not due to any of the above irregularities in the technique, but to the fact that exceptional samples that gave the low lead values *could not be accepted as genuine.*"

In view of the confidence expressed in genuineness of the samples in the bulletin itself, this struck me as a remarkable admission.

Another point to be noted in reference to the relation of the standards to the investigation underlying them is that the methods prescribed for the determination of Canadian and Winton lead numbers and of malic acid value differ from those used in the investigation itself. In the latter, fixed quantities of syrup were used and the results calculated over to the dry basis. The standards, however, prescribe the use of a quantity of syrup or sugar containing a fixed quantity of dry matter. At first sight it may appear that calculation to a basis of 100 grams dry matter must yield results identical with determination upon the quantity of material containing 100 grams dry matter. In the case of the lead values, however, this certainly does not hold true, and the same is probably true of the malic acid value.

Ross[†] has shown that the lead subacetate precipitate is soluble both in excess of the reagent and in sucrose solution. In view of this fact it is clear that the quantities of reagent, precipitable matter, sucrose and water present in a given experiment may all influence the results obtained. Mr. Scott and I[‡] have shown that results obtained in the Canadian method, using the quantity of syrup containing 5 grams of dry matter, are higher than those obtained with the use of 5 grams. of syrup and calculated to the dry basis. We found in four syrups an average difference of 0·36 in the lead numbers obtained by the two modes of working (see Table IV.). In the letter from the Chief Analyst already referred to as based on Mr. Valin's memorandum, there is a sentence which appears to mean that the Inland Revenue chemists have also found that higher results are obtained by the methods of the standards than by the use of the uniform quantity of 5 grams syrup, but that they find a difference of only 0·2 between the results obtained in the two ways. They also claim that results are more concordant when obtained on dry substance, and our experience confirms this conclusion, if thereby is meant that the range of variation in genuine syrups is narrower (see Table V.). Herein there would be a legitimate argument for setting the standard above the minimum found by calculation to dry basis. But as already noted, their letter disclaims all arguments based on technique and confesses a doubt as to the genuineness of some of the samples used in their work. Moreover, there is no reference in the bulletin itself to any difference between results obtained in the two modes.

	Wet basis.	Dry basis.
Average	1·91	2·83
Maximum	4·68	6·56
Minimum	0·89	1·37
	3·79	5·19
Range per cent. average	198	183
Range per cent. minimum ..	426	379

A further criticism that may fairly be urged against the standards is that they give to the terms "Winton lead number" and "malic acid value" significations different from those which they have hitherto held and which they still hold in the United States. The malic acid value has always been determined upon 6·7 grams of the sample, whether syrup or sugar. The results are sometimes calculated over to the dry basis, but this is a different matter from using the quantity of sample containing 6·7 grams dry matter, since the latter procedure alters the relative quantities of calcium chloride, water, alcohol, sugar and malic acid present. The Winton lead number has, likewise, always been determined with the use of 25 grams of syrup, and the procedure of the Canadian standards gives a result different from that obtained by calculating the true Winton number to the dry basis. Curiously enough, the difference is in this instance in the opposite direction from that found in the Canadian lead number. The Canadian standards method for Winton lead number gives lower results than the true Winton lead number calculated to the dry basis, the difference averaging 0·18 in the four syrups examined by us. (See Table IV.) And what is still more remarkable, an examination of McGill's and Bryan's results shows that the range of variation of the Winton lead number is less when the numbers are given on the wet basis than when they are calculated to the dry basis. This is true both of the results as a whole and of the results of each investigator considered separately. (See Table VI.) To reduce Winton lead numbers to a dry matter basis is, therefore, in my opinion, labour wasted.

TABLE VI.

Winton lead number on wet and on dry basis.

Bryan's samples.	Wet basis.	Dry basis.
Average of 481 samples ..	1·78	2·70

Maximum	1·53	2·38
Minimum	0·70	1·05
Difference	0·83	1·33
Range per cent. of average ..	71	76

Finally, there is a general objection to be urged against the prescription of methods requiring the use of quantities of sample containing a fixed quantity of dry matter. This objection refers to the inconvenience of weighing out varying quantities of sample as compared with weighing out fixed quantities. The inconvenience is aggravated by the prescription of a direct drying method for moisture. One must defer commencing the other determinations until the moisture results are available. This means a delay of half-a-day in reaching conclusions. A refractometric determination of moisture would obviate the delay, and I think I am correct in saying that sugar chemists in general have rather more confidence in moisture determinations obtained with the use of a refractometer than in those made directly. But the use of a fixed quantity of sample would be the most convenient arrangement, would put the Winton lead number and malic acid value on the same basis as in the United States, and would, so far as I can see, have no material disadvantage in any respect.[*] The Canadian lead number and the malic acid value could be calculated to the dry basis. The Winton lead number, as we have seen, ought not to be calculated to the dry basis.

A word more as to the method in which the standards have been applied in the single inspection that has been made since their adoption.[†] Canadian lead numbers are given for all the samples examined, but (with two exceptions) it is only where the Canadian lead number falls below the standard that any of the other analytical results are given. This appears to afford the adulterator an opportunity to obtain a clear field for his product by compounding it so as to escape condemnation by this single test. If he can only make it give a Canadian lead number above 1·7 he need pay no attention to the other requirements of the standard.

The Conductivity Test.

At a meeting of the American Chemical Society held in Washington in December, 1911, I described a method of detecting adulteration of maple syrup by measuring the electrical conductivity of a mixture of the syrup with twice its volume of water. This dilution of the syrup was selected because it represents approximately the maximum conductivity obtainable in diluting maple syrup with water. (See Diagrams I. and II.) Results obtained with 68 syrups showed a range of conductivity value (specific conductivity at 25° C. × 105) from 110

---

[*] Jones' method of preparing the sample by reboiling and filtering ought to be adopted.

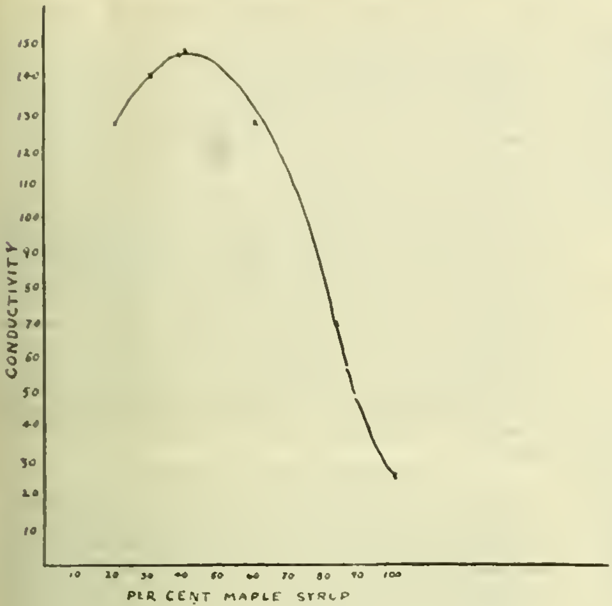

FIG. 1.

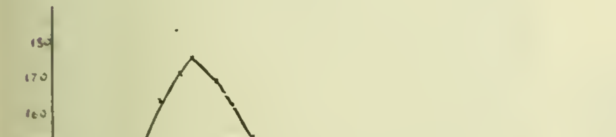

FIG. 2.

to 203. In the discussion of my contribution some one remarked that a syrup of maximum conductivity value could be diluted with nearly an equal volume of pure sucrose syrup and yet come within the range of genuine syrups. This criticism led me to examine the effect which adulteration of genuine maple syrup with syrup of equal density made from granulated sugar has, not only upon the conductivity value, but also upon the other analytical values. The average results of experiments upon three samples of maple syrup are shown in Table VII. They show that the total ash and the Winton lead number fall off proportionally to the content of genuine maple syrup The conductivity value lags behind to some extent, and so, for some undetermined reason, does the alkalinity of the soluble ash. The Canadian lead number is unique in that it falls off more rapidly than the actual maple content. This is a point of distinct advantage for the Canadian lead method.

The value of a method, however, depends not alone upon how much its figure is affected by adulteration but also upon the range which the figure shows in genuine syrups. To get more light upon the range of variation of the conductivity value and at the same time to check the results of the investigation of the Inland Revenue Department, we collected 126 genuine syrups last spring direct from the sugar bushes of Quebec and Ontario. The samples were obtained, some of them by myself, the others by graduates of Macdonald College and the Ontario Agricultural College, occupying positions of responsibility as local agricultural demonstrators. These men were instructed to take no samples about which there could be the least doubt and to take them in the sugar house, whenever practicable A detailed report of our work will appear in the "Journal of Industrial and Engineering Chemistry" at an early date. Its general outcome is to corroborate in the main the evidence of the Inland Revenue investigation as to the composition of genuine Canadian maple syrup. Among our 126 samples representing a variety of conditions of locality, soil and method of manufacture, we find no less than 18 having percentages of total ash below the Vermont standard of 0·77 per cent. We have five below the minimum of 0·69 per cent. found by the Inland Revenue Department, and three of these are just above the limit of the Canadian standard, being 0·61, 0·62 and 0·64, respectively. None of these three syrups contained as much as 35 per cent. of water. It is evident, then, that the Vermont standard on total ash is too high for Canadian syrups. If the principle of adopting the absolute minimum is to prevail, the standard for total ash must remain where it now stands. I think, however, that injustice would be rare under a standard of 0·65 per cent.

In insoluble ash we have not found a sample as low as 0·12, but we have found one at 0·16, one at 0·18, one at 0·21, and one at 0·22—four in all below the Vermont standard. Inasmuch as in the work of Jones, Bryan, McGill and ourselves this determination has been made upon 770 genuine syrups and only one has given a value below 0·16 and only four have given values below 0·19, it appears to me absurd to adopt so low a standard as 0·12. If an insoluble ash requirement is worth introducing into the standard at all, it ought certainly to be set higher. A standard of 0·19 would condemn only one-half of 1 per cent. of the samples which have been investigated.

Our "malic acid values" were determined according to the Canadian standards method. They, therefore, cannot fairly be compared with the Vermont standard, since this refers to true malic acid value. We have three samples among our 126 below the discarded Canadian standard of March, 1911, viz., 0·40 per cent. Two of these are at 0·38, the third at 0·34. If malic acid value is a useful criterion of purity, the requirement of 0·40 per cent. might surely have been retained with but little risk of injustice.

In Canadian lead number, determined according to the standards, we have found no sample as low as the standard. Indeed, we have found but three having values below 2·00. One of these is practically 2·00, viz. 1·98. The others are 1·82 and 1·74 respectively. The latter is the only one approaching the limit of the standard. It would seem that if this determination is to be made as prescribed in the standards, the question of raising the minimum ought to receive further consideration.

In the modified Winton number of the Canadian standar our minimum is 1·41. This minimum is 0·21 above the standard. My objections to the inclusion of this modified Winton lead number in the standard have been stated above, but if it is to be retained, it appears to me that our results on 126 samples, *determined according to the prescribed method*, offer a more secure basis for the selection of a limiting value than do McGill's results on 47 samples, determined on 25 grams syrup and calculated to the dry basis, particularly as his minimum (1·05) is so far below that of Bryan (1·76), obtained by the same procedure upon 481 samples.

TABLE VII.

Effect of adulteration with sucrose syrup on the analytical values.

Average of results on three syrups.

Per cent. of maple syrup in the mixtures.					
Actual	Estimated from				
	Total ash.	Alkalinity sol. ash.	Conductivity.	Winton Pb No.	Canadian Pb No.
90	90·8	99·3	90·2	93·6	82·9
80	76·6	85·2	84·3	81·8	68·3
70	64·7	75·7	74·5	71·8	57·3
60	59·3	65·2	65·6	58·1	43·6
50	53·8	56·4	56·0	50·0	27·5
40	37·9	48·4	46·4	39·4	17·0
30	28·4	37·4	35·9	29·4	7·9
20	20·5	28·9	25·8	22·1	—
10	8·4	13·6	14·3	10·4	—

The minimum conductivity value found in our 126 samples was 112. The lower limit of 110 originally set is thus confirmed. Five samples gave values exceeding the proposed maximum of 200. The highest was 230, the next 219, the others 205, 204 and 202. Four of these five samples were kettle boiled and treated with eggs and milk; and four of the five contained excess of water—though the sample with *highest* conductivity value was of exactly correct density. I conclude that a conductivity value of over 200 is rare and one of over 205 *extremely* rare. No syrup made on a modern evaporator has given a conductivity value of over 200.

Comparison of Ranges of Variation of Analytical Values.

We come now to a very important question, which ought to receive the attention of the Advisory Board on Food Standards, viz.: "Have the most useful analytical values been selected for inclusion in the standard?" I have already referred to the work which Mr. Scott and I have published in reference to the rate of falling-off of values as syrup is adulterated with more and more cane-sugar, and have pointed out the advantage which, in this respect, the Canadian lead method has over all others. But another criterion has also to be applied in the comparison of analytical values to determine their usefulness, viz.: "What range of variation does each analytical value show in genuine maple products?" The four large investigations of genuine syrup (those of Jones, Bryan, McGill and ourselves) furnish data for the answer to this question. Table VIII. shows the number of analyses of genuine syrup in which each of these values has been determined, the maximum, minimum, and average results which have been obtained, and the range of variation of each analytical value, expressed first in per cent. of the average, and secondly in per cent. of the minimum. It will be observed that the conductivity value makes the best showing of all in this comparison, the total ash and the alkalinity of the soluble ash come next, then the weight of the soluble ash and the Winton lead number, this being the true Winton number calculated to a dry-matter basis. On the wet basis, as we have seen, the Winton number makes a better showing, and it comes out still better if either Bryan's results or McGill's results are considered alone. The malic acid value and the insoluble ash, to which Prof. Jones has attached so much importance, make the poorest showing of all the values, and the ash-ratios are equally poor.

A Scheme of Rapid Analysis.

It is a point of much practical importance to the analyst that the values showing the narrowest range of variation in genuine syrups are also values which can be quickly and easily determined. In our contribution to the Journal of Industrial and Engineering Chemistry Mr. Scott and I are proposing a scheme of rapid analysis embracing six determinations involving less than an hour's actual attention, which we hope will prove adequate to detect adulteration in the great majority of instances. The scheme is outlined in Table IX. The figures for total ash, alkalinity of soluble ash, and Canadian lead number are to be *calculated* to dry basis, but the Winton lead number and the conductivity value are not. It should be noted that the insoluble ash is left upon the filter, so that if the results of the rapid scheme leave room for doubt, one can ignite, weigh and titrate the insoluble ash, and thus get all the usual analytical data with the exception of the malic acid value. It is our hope that this latter troublesome determination, in which apparently no two analysts can get accordant results, may always be found to be quite superfluous.

We have placed the conductivity method first, not because it is our own, but because we believe that it, by itself, is capable of settling the question in many instances. In other words, we believe that no syrup which does not show a normal conductivity value can be genuine. We have not a great deal of data upon this point. But in 1911 and 1912 we examined 34 samples of syrup which were on sale in the Western Provinces. Fifteen of these gave conductivity values below the minimum found in genuine syrups and all fifteen were shown to be adulterated by other tests. These fifteen, we maintain, might have been condemned on the strength of the conductivity test alone. The other tests which we made upon the 34 syrups revealed

TABLE VIII.

Analytical values in genuine maple syrups.

Value.	No. of analyses.	Maximum.	Minimum.	Average.	Range.

adulteration in only two others, neither of which, however, professed to be pure. One of these two was low in all the other values determined, the other in total, ash only.

Maple Sugar-making as an Agricultural Industry.

Maple sugar-making has been from the first, and, so far as one can see, must continue to be, an agricultural industry. The fact that it is only for a few weeks in the spring that sap can be obtained in quantity and of quality suitable for sugar-making and that during those weeks the melting of the snow renders the roads nearly impassable, prevents the organisation of the industry in a manner that would render it possible to use the highly economical evaporating apparatus which is employed in the beet and cane sugar industries. Multiple effect vacuum pans are out of the question for a single farmer or even for the number of farmers that could deliver sap at a central station. The enormous amount of fuel consumed in evaporation at atmospheric pressure is apt to shock the sugar refinery man. With the most modern apparatus from seven to twelve cords of wood are used in the manufacture of a ton of maple sugar. But it must be remembered that the wood is close at hand and can be collected and prepared at very little cost. Two dollars a cord is perhaps a fair estimate of its value. Coal is but little used, and if wood is eventually to be displaced as a fuel it is not unlikely that it will be liquid fuel, rather than coal, which will take its place.

According to the census of 1911, the total production in the Dominion of Canada in 1910 was 12,178,216 pounds of sugar and 1,066,971 gallons of syrup (see Table X.). The combined value was $2,569,233, of which Quebec contributed nearly two-thirds and Ontario nearly one-third, the other provinces contributing only 3 per cent. altogether. The production of sugar in the United States in 1909 was not two million pounds greater than that in Canada in 1910, but the syrup produced in the States was nearly four times he Canadian output. The total value of the maple products n the United States in 1909 was almost exactly twice that of Canada in 1910.

TABLE X.

Canadian Census returns on maple sap products in 1910.

	Sugar lb.	Syrup gallons.	Value $	Per cent. of total value.
Quebec	9,427,694	984,282	1,680,393	65
Ontario	2,510,207	58,018	831,483	32
New Brunswick	143,779	18,211	37,337	3
Nova Scotia	96,315	6,424	19,785	
Prince Edward Island	206	16	82	
Manitoba	15	20	153	
Dominion of Canada	12,178,216	1,066,971	$2,569,233	100

The production of sugar in the United States in 1909 was 18 per cent. greater and the production of syrup early 50 per cent. greater than in 1899. The production of syrup and sugar in Quebec in 1910 was 35 per cent. greater than in 1900, but the value of the product had increased by only 24 per cent. In Ontario there was a falling-off of 22·5 per cent. in production in 1910 as compared with 1900. It ought to be noted, however, that the annual production in any locality varies considerably from year to year on account of variations in weather and other conditions.

The relative importance of the maple crop in the Province of Quebec as compared with some other farm products is shown in Table XI.

TABLE XI.

Maple compared with other farm products.

Province of Quebec Census of 1911.

Meeting held at Burlington House, on Monday, May 4th, 1914.

PROF. W. R. HODGKINSON IN THE CHAIR.

APPARATUS FOR THE AUTOMATIC MEASURING AND INJECTION OF CHEMICALS.

BY THE HON. R. C. PARSONS, M.A., M.INST.C.E.

Having devoted much attention to the filtration of water on an extensive scale, both by means of the ordinary sand filter, and more recently by the mechanical filter, it was found to be necessary in some instances to add a chemical to the water, previous to its passing through a filter, so as to obtain a clear effluent.

The methods for adding the requisite quantity of chemical in a constant proportion to the water to be treated, although the flow of the latter may vary considerably, form the subject to be discussed in this paper.

In connection with the water supplies of the populous cities of the Argentine Republic, South America, where the water is frequently obtained from the River Plate, extensive filtration plants have been installed. The water of this river is charged with very finely divided alluvial matter, and as is the case with the water of the River Nile, requires special appliances to ensure its being thoroughly cleansed by filtration. In the case of the City of Buenos Ayres, with the Water Works of which the author was connected as Consulting Engineer some years ago, the consumption of water was 60,000,000 gallons per day, drawn from the River Plate; the filtration was effected entirely by means of gravitation sand filters, and it was found impossible to ensure a clear filtrate without the employment of some form of coagulent.

The chemical experimented with in that case was aluminium sulphate, which when added to the water, previous to its entering the settling pools, was found to yield a clear effluent when passed through sand filters. The use of this chemical has since been constantly continued, and the method of adding it to the water to be treated is by tipping definite quantities of the salt into tanks of known capacity, and from these the solution is pumped into the settling pools with a rapidity regulated arbitrarily by the superintendent in charge.

It will be realised that with this rough and ready method of control there is at times too much chemical added which leads to the corrosion of the water mains throughout the city, and is also deleterious to the health of the population, but at others too little, in which case there is not sufficient to clarify the water.

An equally unsatisfactory method was in operation at the water works of the city of Rosario de Santa Fe, where the consumption of water, derived from the Rio Paraná, now amounts to 12,000,000 gallons per day, but in this case the chemical employed is alumino-ferric salt.

It was realised by the Directors of the Water Works Company that as the consumption of chemical was considerable, and consequently an important item in the working expenses, it would be advisable to adopt some more scientific method for adding the chemical to the water to be treated. The author was instructed to consider the question, and advise as to what course should be adopted.

In the first instance the various methods then in use for adding chemicals to water, previous to its passing on to filters were examined, and as none appeared to fulfil the necessary requirements, the author devised the apparatus known as the "Tiltometer," a detailed description of which was read before the Society of Dyers and Colourists in March 1912.

An elevation of this instrument is shown in Figure 1, and it may be described as essentially a low pressure injector, or one which is only capable of injecting the chemical into a main having a head not greater than the elevation of the point, L.

The water flows from the crude liquid tank to that for the treated liquid through a main in which is a Venturi tube, A, of the ordinary type, and as is well known, when a current is flowing through the main a reduction of pressure is produced at any point where the main is contracted in sectional area. This difference of pressure is termed the Venturi head. Thus at the point A the pressure is less than that existing in the main on either side of it. B and C are two vertical cylinders, and these are connected at their lower ends by pipes, one to the contracted main at the point, A, and the other to the main at its normal section.

Within the cylinders, B and C, are plungers, whose weight is greater than that of the water they displace, and of such diameter that they can rise and fall without touching the sides of the cylinders. These plungers are attached to either end of a lever pivotted at its central point on knife edges E. A means of adjustment is provided in the rod connecting one of the plungers to the end of the lever. Attached to this lever, and concentric with its axis, is a cylindrical tank having an opening at the top through which the chemical reagent enters. The height of the solution in it is maintained accurately constant by means of a ball valve. From the circumference of the cylindrical tank extends a projection containing an adjustable orifice which allows the chemical reagent to flow out of the tank and fall into the cup L, from which it enters the water to be treated, flowing along the main. This orifice being in the form of a diamond or one with parallel sides, preserves the same shape for all degrees of opening, and is found to possess a practically constant coefficient of discharge.

It is well known that the difference of pressure recorded in a Venturi tube varies as the square of the velocity of the water flowing along the main in which it is placed, therefore the difference of level in the two cylinders, B and C, varies in the same ratio. The plungers, F and G, rise and fall with these changes of level, and they in their turn rotate the cylindrical tank, the orifice of which thus becomes immersed at a depth below the surface of the solution in the cylindrical tank, depending upon the angle of rotation. Further, the flow of solution through this orifice varies as the square root of the depth of its submersion, consequently for any variation of flow in the water main a similar variation takes place in the flow of the reagent into the mains, and the percentage of chemical added continues constant.

Theoretically, therefore, the action of the apparatus would be perfect if it were possible to avoid certain errors connected with the Venturi effect, and also with the passage of the chemical through the orifice; yet these are so nearly eliminated that the practical error under extreme conditions of working, does not exceed $1\frac{2}{3}$ per cent.

The following are the results o tests made upon a large apparatus constructed substantially as show in Figure 1, and which has been i constant service for a considerabl period :—

TABLE 1.

1820	57·2	3·14
2390	73·7	3·08

The first column indicates the flo of water in the main. The second t chemical added. The third the rat of columns one and two

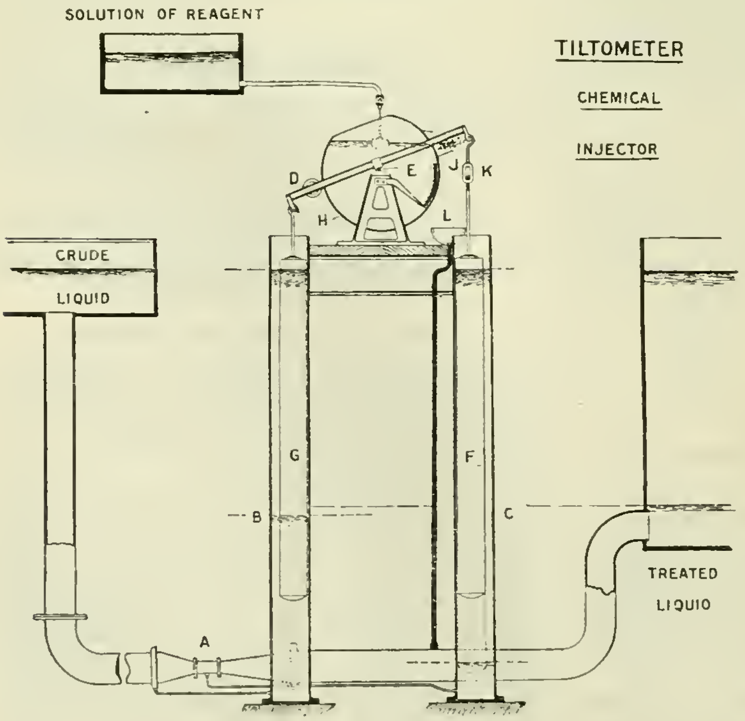

FIG. 1.

As a rule it is advisable to use a standard solution of reagent, and to give a practical example of the working of the apparatus just described, a case may be cited where the flow in the main varies from nothing up to 1,000 gallons per hour, and requires to have 7 grains of alumino ferric salt added to each gallon. In this case the Venturi tube will be 4 inches diameter, narrowing to 2 inches in the throat. The difference of level in the two cylinders B and C, when 1,000 gallons per hour is passing, will be about 2 feet, which will impose a head of about 12 inches upon the orifice J in the cylindrical tank.

The strength of the solution might for simplicity be 1 of alumino-ferric salt to 70 of water, or 1,000 grains to the gallon. If therefore 7 gallons of the solution is added to each 1,000 gallons passing through the mains, the required treatment is effected.

The diameter of the orifice J in this case will be about 3/32nds of an inch in diameter.

At the Water Works of Rosario above mentioned where two Tiltometers are being installed, the method employed for determining the percentage of chemical to be added to a water, such as that of the River Plate, is by ascertaining the degree of turbidity by the usual method of viewing an object through a column of water, and measuring the length of the column when it becomes invisible. A scale is then prepared which enables the attendant to set the orifice, after which the variation of the flow is taken charge of by the apparatus, automatically. Should the river water become more or less turbid, then the orifice is again adjusted in a similar manner. The volume of chemical passing through the Tiltometer is indicated by the pointer on the side of the cylindrical tank.

FIG. 2.

Having described the principle and the operation of the "Tiltometer," several of which are in operation and working entirely satisfactorily, the "High Pressure Chemical Injector" will now be explained.

In view of mechanical filtration now being adopted very largely, and with it the chemical treatment of the crude water being found advisable, the injection of the chemical into the water mains under pressure has been found necessary. As the result of numerous investigations and experiments the apparatus which will now be described has been found to yield satisfactory results.

Figure 2 shows a sectional elevation of this apparatus. The motive power of the "High Pressure Chemical Injector" is, as in the "Tiltometer," derived from the difference between the actual pressure in the water main and that in the throat of a Venturi tube inserted therein. This is the best method of obtaining the required difference of pressure, as it involves the least possible loss of head in the mains.

The injecting apparatus consists of two cylinders of equal diameter, in which solid pistons slightly heavier than the fluid they displace, and having wide circumferential grooves, move quite freely; that marked A being termed the working cylinder, whilst that marked B the secondary cylinder. Below the working cylinder are situated the controlling valve gear and valves for the admission and release of the actuating fluid, to and from both cylinders. These consist of a telescopic rod 10 attached to the lower end of the piston in the working cylinder. The lower extremity of this rod is attached to a fork which engages the valve spindle 11, and by means of adjustable tappets on it moves the slide valve (1) each time the piston completes its stroke in either direction. This valve then admits the pressure of the mains alternately to either end of the cylindrical valve (2, 2) and also simultaneously exhausts it from the opposite end. At both ends of this cylindrical valve are cup leathers for preventing leakage occurring past the ends of the valve. In the cylindrical valve, between the cup leathers, are the necessary ports for admitting the working fluid to both cylinders A and B alternately and releasing it from them. Below the secondary cylinder B is an inlet valve kept open by means of a spiral spring 16 until forcibly closed by contact with a projection on the lower end of the piston, on the completion of its downward stroke. Above each cylinder is an upper valve box, each containing an inlet and outlet valve which consist of thin flat discs of pure soft rubber. Between the upper valve boxes and also the lower valve boxes and the two cylinders are provided glass cylinders (8, 8) which are useful for enabling the attendant to observe the important working parts of the apparatus.

The standard solution of chemical to be injected is stored in a tank situated some ten feet above the apparatus, and a pipe connects it with the inlet valves of the upper valve boxes. The inlet pipe for the high pressure water connects the main with the back of the cylindrical valve and the delivery pipe connects the outlet valves of the upper valve boxes with the throat of the Venturi tube. Upon this last-mentioned pipe is the valve (18) of special construction, the orifice of which is diamond shaped, which, as already stated, ensures its preserving the same form at all stages of opening, so as to maintain a practically constant coefficient of flow for all openings.

It should be explained that it is obviously impossible to exhibit in this room the injector forcing chemical into a water main. In order, however, to produce a similar effect, an additional valve is fixed on the outlet pipe beyond the regulating valve. By more or less closing this valve the throat pressure of the main is imitated. The chemical after it passes through the small Venturi is then returned to the chemical tank, and for exhibition the action of the injector is therefore continuous.

In order to prevent any deposit occurring in the passages and chambers, care is taken that still liquid shall not exist at any point. A vortex action is therefore maintained in the chambers by the in and out flow of the chemical, which has proved to be quite effectual.

Action of the apparatus.

The action of the apparatus is as follows :—The pistons A and B being at the lower end of their respective strokes, and the upper valve boxes full of chemical, the working fluid is admitted to the apparatus, and the cylindrical valve then allows it to flow to the under side of piston A. This piston immediately commences to rise, injecting the chemical above, and continuing to do so until it reaches the end of its upward stroke. At this point the rod (10) moves the valve (1) which admits the high pressure water to the lower end of the cylindrical valve, which on rising opens the release port and allows the piston A to descend. The same movement of the cylindrical valve admits the working fluid to the lower end of cylinder B, the piston in which immediately commences to rise, injecting the chemical at the same rate as was previously done by piston A, and continues the process of injection.

The upward movement of piston B only continues until piston A has completed its downward stroke, and is ready to recommence the operation of injection. The cylindrical valve is then moved downwards and piston A again rises, while piston B moves downwards to the end of its stroke so as to be ready to take its place again when piston A has reached the top of its stroke.

With this cycle of operations the injection of the chemical, except during the momentary shifting of the valves, is constant. The stroke of piston A is thus always of constant length, but this is not the case with piston B, the stroke of which is of a variable length, depending upon the rapidity with which the Injector is working.

An injector capable of injecting 40 gallons of chemical per hour against any pressure was exhibited at the meeting. Both cylinders were 3 inches diameter, and the stroke of piston A was 4 inches, whilst that of B varied considerably, depending upon the time occupied by the return stroke of piston A.

Careful tests were made with this injector, some of which are given in the above table. The first column indicates the amount that the regulating valve is open. The second is the Venturi pressure actuating the Injector. The third is the calculated flow of water through a main to produce this Venturi pressure. The fourth is the quantity of chemical passed by the Injector in gallons per minute as weighed. The fifth is the percentage ratio of the third and fourth columns. These figures indicate that the apparatus gives very accurate results over a tolerably wide range of flow through the main, which in the case in question amounted to a ratio of 1 to 7.

In order to adapt the High Pressure Chemical Injector to practical requirements, it was necessary to provide an easy method for indicating at any moment the quantity of chemical being injected in a given time.

It was found advisable to make use of a small Venturi tube for this purpose, and in Plate III., which is an illustration of the apparatus exhibited, a Venturi tube is attached on the right hand side, with the requisite manometer above it. It will be observed that there is a difference in the height of the columns, indicating that a current of the chemical is passing through the tube, and by reference to the discharge diagram of this Venturi tube, the flow at any time can be ascertained.

On the opposite side of the Injector is another manometer, the columns of which are attached, one to the water main, and the other to the throat, of the Venturi tube inserted in it. The difference of the height of these columns when referred to the discharge diagram of this Venturi tube, gives the flow through the main. By comparing the readings from these two manometers the percentage of chemical introduced into the water to be treated is at once ascertained. Should the required percentage not be correct, then by a slight adjustment of the regulating valve on the outlet from the injector, the necessary alteration may be made, which then continues constant, although the flow in the main varies.

The following diagrams A, B, C, D, E, indicate the relative movements of the water in the main and the chemical discharged by the Injector. The parabolic curve in each is that universally used for ascertaining the flow through a main in which a Venturi tube is inserted, when the Venturi head is observed on the Manometer on the left hand side of the Injector. The tube selected for consideration is one of 3 inches diameter with a throat ratio of 4 to 1. The small circles which form a curve, which practically coincides with this curve, are those of the flow of the chemical as indicated by the Venturi head in the manometer, on the right hand side ; the observations on both manometers being taken simultaneously. Both curves practically coincide, showing that the apparatus works with great accuracy.

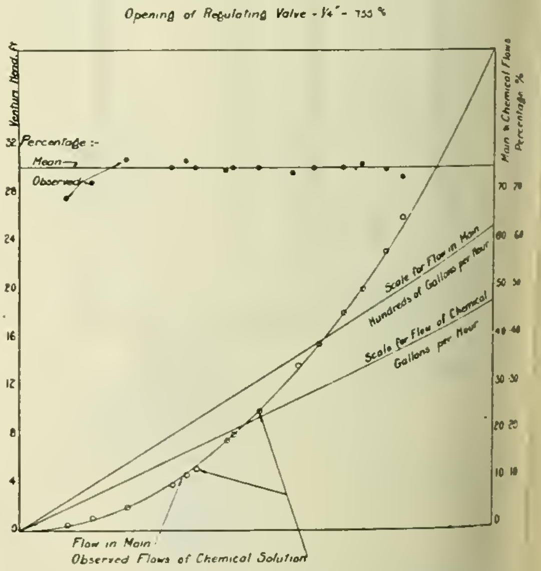

DIAGRAM A.

On these diagrams are also drawn two straight lin starting from the origin, the upper one showing the di charge through the 3 inch main above mentioned when t

Venturi tube in it produces the respective heads on the manometer. The lower line in the same manner indicates the flow of chemical through the small Venturi tube at the various heads shown on its manometer. The horizontal straight line shows the mean percentage of chemical it is desired to inject into the main, and the circles along it indicate the actual observed results, which very nearly coincide with it.

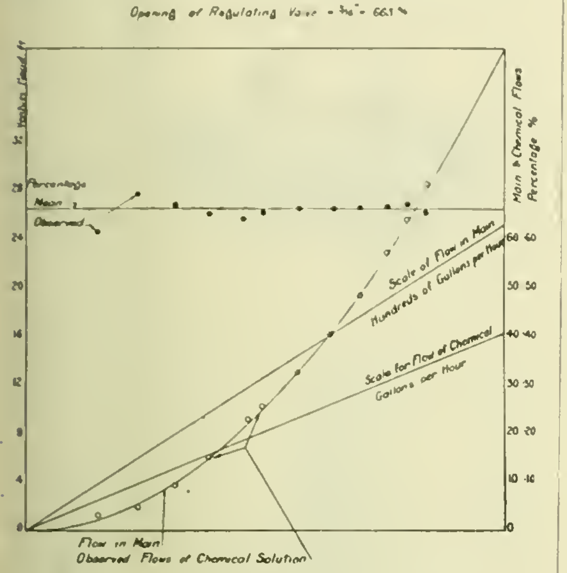

DIAGRAM B.

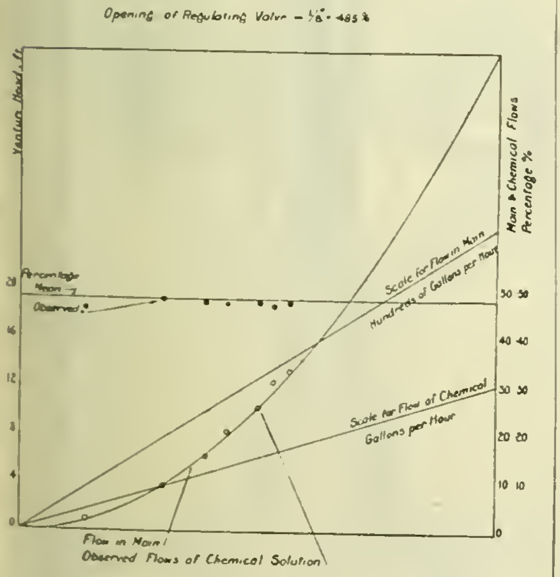

DIAGRAM C.

The results of the tests given in the table, and also those indicated in the diagrams, prove that the apparatus gives very accurate results when working with a range of flow in the main of 1—7, and a variation of percentage of chemical of 1—5, but should greater ranges be required, special arrangements can be made.

The reason for the accuracy of these results being obtained can be easily explained. The Venturi head in the water main varies as the square of the flow, further the fluid friction through the passages of the injector and the regulating valve also vary as the square of the flow. Further the measurement of the discharge of chemicals is by a Venturi tube, the head of which varies as the square of the flow. Consequently if there was no mechanical friction in the apparatus, it should give practically perfect results, as was the case with the "Tiltometer." The only disturbing influence is any mechanical friction, which, owing to the special construction of the apparatus, is reduced to almost nothing, which is proved by the fact that the Injector will work with a water pressure of less than $\frac{1}{2}$ an inch of mercury.

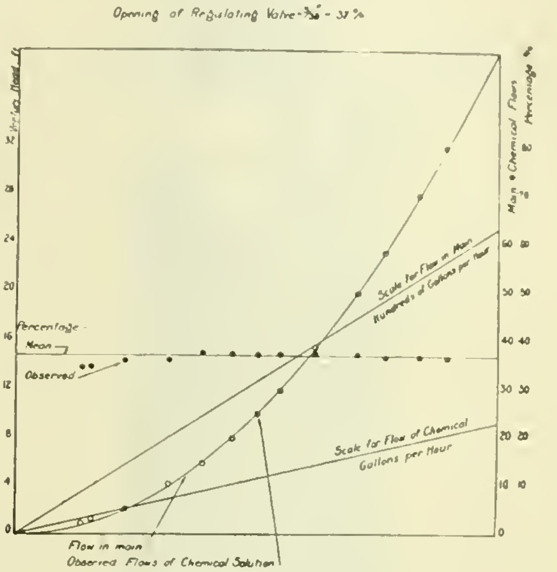

DIAGRAM D.

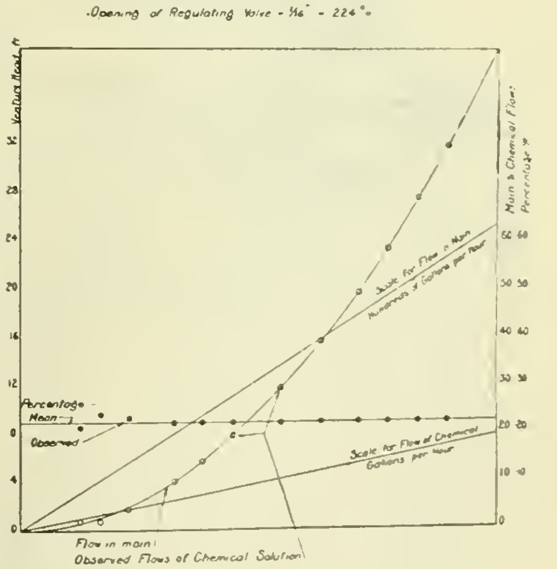

DIAGRAM E.

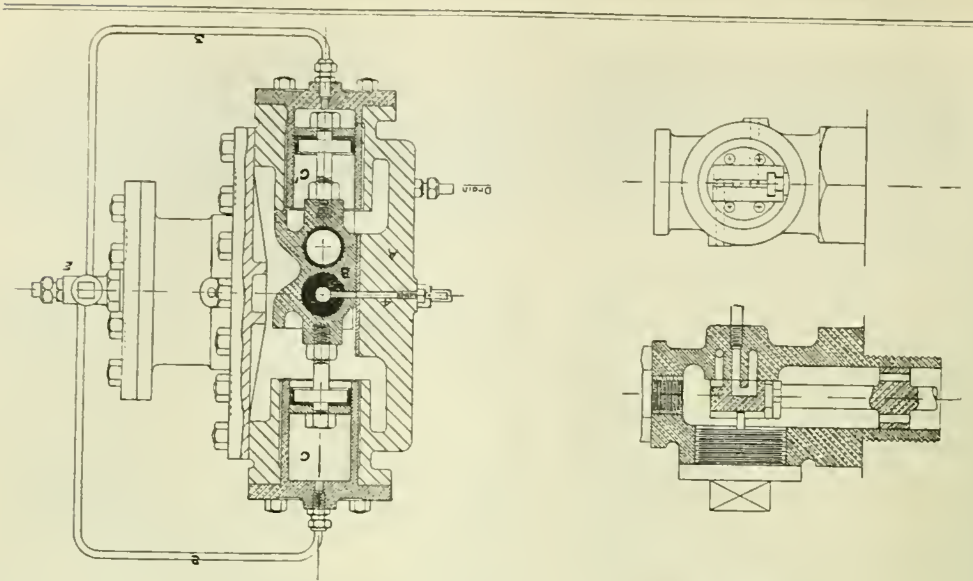
The pistons are quite loose fits in the cylinders, and are slightly heavier than the fluid they displace. There is, therefore, a small leak of water past them, which is in an upward direction, except at the conclusion of the downward stroke, when at the moment of reversing the valves, it is a leak of chemical in a downward direction. To prevent any passage of the upper liquid into the lower due to these leaks the piston is provided with deep circumferential grooves in which the fluid due to leakage in



Automatic Shifting Valve.

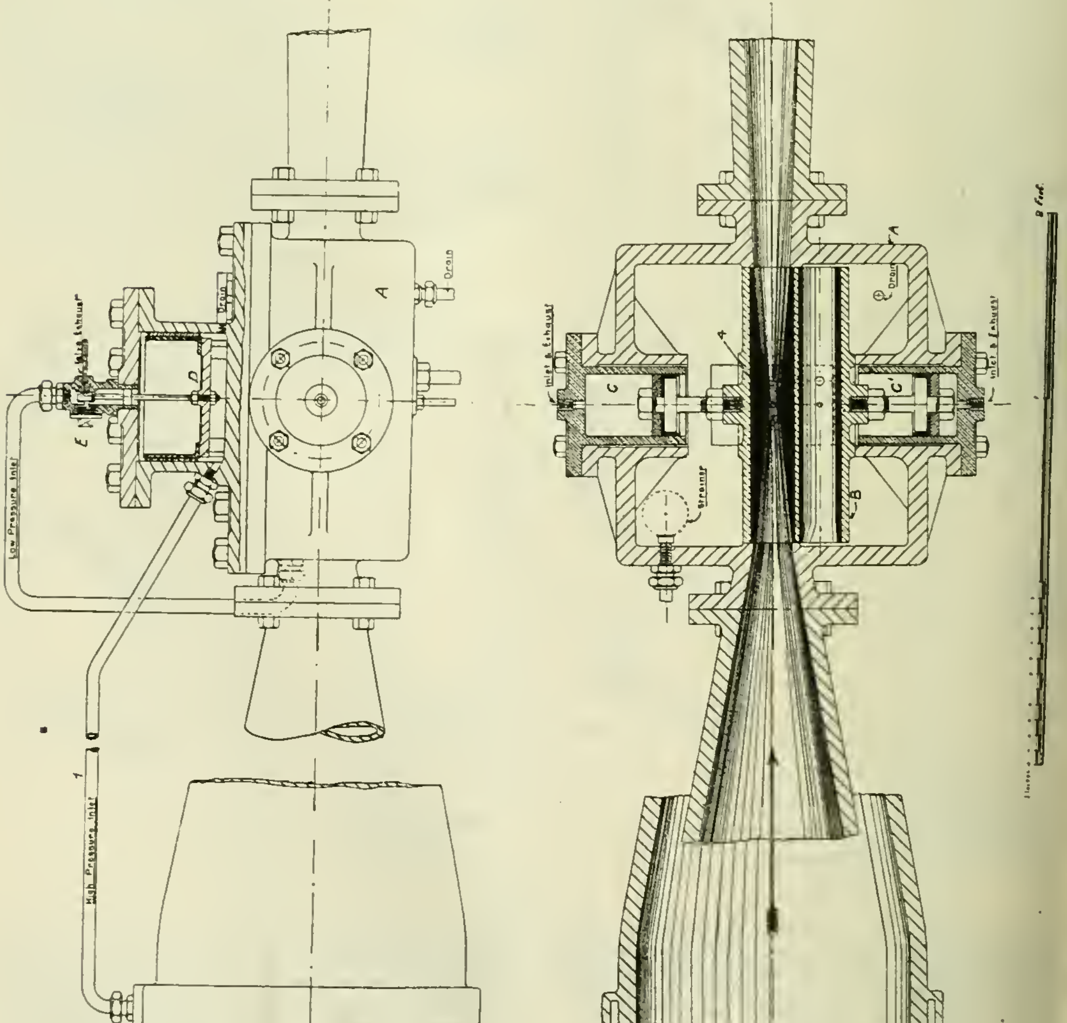


FIG. 3.

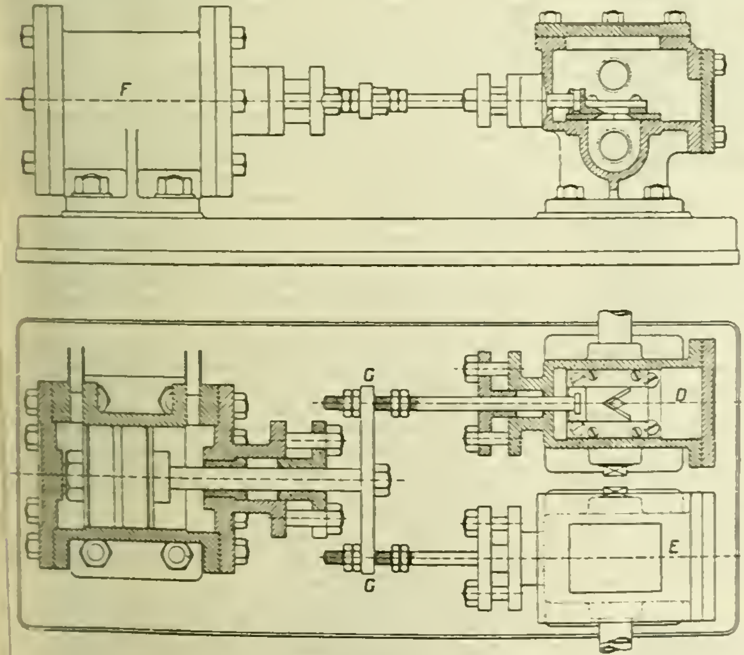
a downward direction is stored and is returned by the similar leakage in the upward direction, consequently there is no loss of chemical.

Tho movement of the cylindrical valve which controls the movement of the pistons is worked entirely by the pressure of the mains, and not by the Venturi head. Consequently it does not interfere with the accurate working of the apparatus.

The apparatus exhibited gave accurate results with a variation of flow in the main up to 1 to 7. There are instances, however, in water supplies where the variation reaches 1 to 30, and the following device can be adopted to meet this requirement.

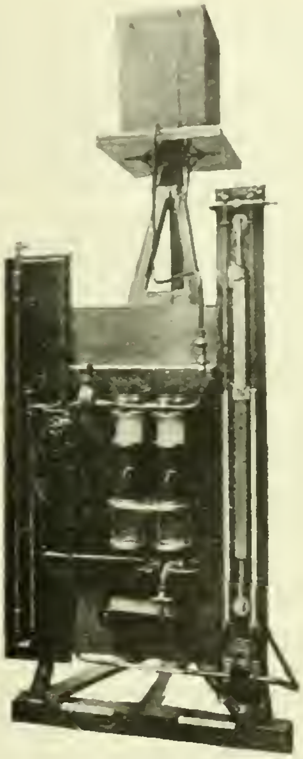
Figure 3 shows a Venturi tube specially constructed, having a rectangular metal box A, termed the Shuttle Box inserted where the throat is usually situated. Within this box is fitted a moveable sliding piece termed the Shuttle (B), in which there are two cylindrical passages or throats, the ends of both of which are of the same diameter as the Venturi tubes leading away from it on either side. One of these throats is of the same diameter throughout, and the second is contracted in the middle.

If the flow of the water through the main is small then the small throat is used, while when it increases to a definite amount the larger throat is called into operation. This is effected by releasing the water pressure from the outer end of one cylinder (C), or the other (C_1), the internal pressure against both pistons being equal. Assuming that the smaller throat is in operation, and the flow in the main increases, which in turn produces a Venturi head as between the main and the shuttle box, the pressure flows along pipe I under piston D, which is quite a loose fit, and is weighted to any desired amount, preferably equivalent to a Venturi head of 30 feet of water. When this pressure is reached the piston rises and moves the slide valve E, releasing the high pressure water from the end of the cylinder by means of the pipe 2. As soon as the flow in the mains falls to the same above mentioned limit, the piston D falls, and the small throat is again brought into service. The shuttle as it moves to and fro slides upon the flat surface of the box in which there is a port connecting either with the wide or narrow throats, whichever is in operation at the time. This port is connected by a pipe with the outlet ports of the Injector.



Regulating Valve.

Fig. 4.



As the admission of chemical to the main is much larger when the large throat is in use than when the small one is in service, it is necessary that the operation of changing the throats shall also simultaneously change the regulating valve (Fig. 4). This is done by means of cylinder, F, into either end of which the high pressure water is admitted at the same time as to C or C_1. The tappets, G, give the necessary adjustments to regulate the percentage of chemical, and when these are set for any given percentage the remainder of the operations are effected entirely automatically, following the variations in the flow through the main.

In the apparatus exhibited the chemical is milk of lime, composed of whiting 1, water 20, and this has no corrosive action on the brass of which the injector is made. If, however, the chemical be of a corrosive nature then the parts exposed to it are made of vulcanite or one of the non-corrosive alloys.

Special attention has been devoted to producing an injector which, whilst possessing extreme accuracy, is reliable in its action, is not subject to wear and tear, and above all is not costly to manufacture. It is believed that the apparatus exhibited possesses all these qualifications, and can be employed for all purposes where it is required to mix one fluid with another in definite and constant proportions.

Note.—Should any further information be required beyond that contained in the paper, it can be obtained by application to The Stereophagus Pump and Engineering Co., Ltd., 39, Victoria Street, London, S.W.

THE APPLICATION OF JETS FOR MIXING PURPOSES.

BY OSKAR NAGEL, PH.D.

Jet appliances consist principally of two or more nozzles of increasing diameter and so connected with each other that the jet of gas or liquid passes from a narrow to a wider nozzle, whereby a vacuum is created, and the material that is to be moved, is transported by the jet, which acts as motor. Such apparatus is easily handled, has no moving parts, and requires little repair, so that its low efficiency as a motor is not a drawback when used only for intermittent work. The injector, however, occupies an exceptional position, since the heat energy of the steam is recovered by being returned to the boiler.

The low efficiency of jet apparatus as "transporters" is caused by the fact that about 75 per cent. of the energy of the jet is consumed in the whirl, which is formed at the transit of the jet from one nozzle to the other. This whirl effects so intimate a mixture of the motor jet with the medium to be moved, that it is a matter of surprise that jet appliances have not been used as "mixers," rather than "transporters."

The chemical industry rather lacks mixing appliances for gases and liquids, and the jet apparatus is wel worth consideration for certain operations. One of these is the chamber process of manufacturing sulphuric acid, which requires chambers of very large dimensions in order to mix the gases thoroughly during their passage. Were it possible to introduce the gases as a perfect mixture into the chamber, its dimensions could be much reduced.

While this apparatus has been recommended for moving the gases through the chamber system, its effect as a mixing machine has been entirely overlooked.

In order to use the jet blower as a mixer it must be connected with the system in a different way from what it would be if used for the transportation of gases. It is not enough to lead steam jets through the wall of the chamber, nor to install a steam jet blower without housing into the pipe coming from the Glover. With such an installation only a part of the gases would get incorporated into the whirl and a partial mixture only would take place. In order to effect a perfect mixture, the whole of the gas must be forced through the nozzles. This is accomplished by tightly connecting the gas pipe of the system, preferably that part which leads from the Glover to the first chamber, with the inlet opening of the steam jet blower.

In order to prevent the gases from entering the chamber at too high a temperature it is advisable to enlarge the lower part of the casing of the steam jet blower. In the space so gained a tubular cooler is provided (for either air or water) in order to cool the gases to 65° C. The gases travel from the Glover through the jet blower to a small chamber and from here through two reaction towers to the Gay Lussac.

In order to increase the mixing effect of the apparatus as much as possible and to reduce the "motor-effect" of the jet it is best to have the gas delivered at the inlet opening of the apparatus at atmospheric pressure, so that the function of the jet blower is exclusively to mix the gases, the latter being delivered at the outlet of the apparatus at atmospheric pressure. By this mode of working the efficiency of the jet as a mixing machine reaches a maximum, at which 20 cb.m. of air is drawn through the nozzle by means of 1 kilo. of steam of 2 atmospheres.

It is clear from these figures that in the chamber process less steam is needed for effecting the mixture of the gases than is required for the reaction leading to the formation of sulphuric acid. The plus of steam necessary for the formation of the acid can either also be sent through the jet apparatus (in which case the apparatus would need to be correspondingly larger), the energy of the plus steam being utilised for the increase of the draught in the chambers, or it may be injected directly into the chamber by means of spray nozzles.

Preliminary experiments show that for a plant in which 3150 kilos. of sulphur are burnt per day, a chamber of a capacity of 850 cubic meters may be sufficient, if after the chamber two reaction towers are provided. The first tower should contain about 20 layers of 20 plates, the second about 30 layers of 12 plates each.

While we are able to utilize the steam jet as a mixer in the chamber process, we can with the same convenience apply the liquid jet in the contact process. In this case sulphuric acid is used as "motor" liquid, while trioxide is the material to be drawn into the whirl. By using a water jet condenser very satisfactory results are obtained in this process of absorption and also in other processes of similar nature.

An effect in many respects similar to that of jet apparatus is obtained by spray nozzles, since the spray, in forming a hollow cone, creates a vacuum in the direction of its motion. On the other hand the spray is also a mixing machine and adapted to effect absorption of large volumes of gases with small volumes of liquids. For this purpose the spray nozzle must be enclosed in a suitable cover in order to force every particle of the gas through the hollow cone of the sprayed liquid.

Meeting held at Burlington House, on Monday, May 4th 1914.

MR. W. F. REID IN THE CHAIR.

A REACTION OF TETRANITROMETHANE.

BY PROF. W. R. HODGKINSON AND CAPT. F. R. J. HOARE.

Some time ago (Chem. Soc. Trans., 1910, 2099) an easy method of formation of tetranitromethane from acetic anhydride was described by F. D. Chattaway.

A small quantity was given to me by the author for trial if if could be employed for a particular technical purpose. Incidentally it was found that in alcoholic-ammoniacal solution certain metals—as copper and nickel—caused a somewhat vigorous action with subsequent separation of a crystalline substance, whilst other metals, as iron and aluminium, were under the same conditions quite inert. After a number of experiments it was observed that only those metals were active which form amides or amino-like compounds, as copper, zinc, cadmium and nickel, directly on contact with air, ammonia and water.

Tetranitromethane is freely soluble in alcohol and acetone. These solutions do not act upon metals until ammonia is added. A yellow colouration then develops, the temperature rises, and there is a slight evolution of gas (nitrogen, carbon dioxide).

As the action on copper was observed only to becom vigorous after a small quantity of the blue cupramin compound had formed, a cupramine solution was adde to an alcoholic solution of tetranitromethane. Crystal formed almost immediately. Analysis of these showe them to be identical in composition with those forme from the metal in an ammoniacal-alcoholic solution o tetranitromethane.

Similar results were obtained with nickel, zinc an cadmium-amine-solutions, and later it was found tha the same compounds were also produced by adding a ammonuim (double) salt, such as nickel-ammonium nitrat to the tetranitromethane solution.

These compounds crystallised well from hot absolu alcohol or acetone but hydrolysed somewhat rapidly heating with water. The result of the hydrolysis of t nickel compound led to the observation that when tetr nitromethane is dissolved in alcoholic ammonia some nit formamine, $C(NO_2)_3NH_2$, results, alcohol at the same ti becoming oxidised. Analysis for nitrogen by combusti in vacuum tube gave N_2 33·7 and 33·5; calculated $C(NO_2)_3NH_2$, 33·7 per cent.

Crystallised from ammoniacal alcoholic soluti the nickel salt appears to have the compositi $[C(NO_2)_3NH]_2Ni.3NH_3.H_2O$.

Analysis: Nickel—mean of 3 analyses, 12 7; nitrog 34·4 and 34·8. Calculated, Ni 12·9; N_2 34·5 per ce

Copper salt $[C(NO_2)_3NH]_2Cu.3NH_3.H_2O$. Found, Cu 1 per cent.; N_2 31·03 per cent. Calculated, Cu 13·07 cent.; N_2 30·94 per cent. The silver salt prepared f ammonio silver nitrate in a similar manner to the others gave on analysis :—silver, 36·18 and 36·35; nitrogen, 25·65 and 25·63 per cent. Calculated for

$((C(NO_2)_2NHAg)3NH_3$, Ag 35·9, N_2 25·7 per cent.

Molecular weight determination (boiling point) in acetone gave results distinctly confirmatory of the above formula, but ammonia seems to be split off from these compounds by long heating in acetone or alcohol. All these substances explode or burn rapidly when heated and are also sensitive when dry to percussion or friction.

Beyond the analyses and ebullioscopic molecular weight determination, no proof of the above formula is at present put forward.

Manchester Section.

MR. J. H. HOSEASON IN THE CHAIR.

EXPERIMENTS ON THE OXIDATION OF SEWAGE WITHOUT THE AID OF FILTERS.

BY EDWARD ARDERN, M.SC., AND WILLIAM T. LOCKETT, M.SC.

It has long been known that if sewage be exposed to the air for a sufficient period of time, the organic contents are gradually oxidised, with the formation of a deposit of so-called "humus" and the final production of nitrate from the ammonium salts and the nitrogenous organic matter.

This purification change of which the course of the reaction has been so carefully studied and thoroughly worked out by Adeney in his researches on behalf of the Royal Commission on Sewage Disposal, takes place, however, comparatively slowly, and even if aided by direct aeration, by no means becomes a practical method of sewage purification.

Numerous investigators have from time to time endeavoured to utilise aeration methods in the practical solution of the sewage problem, but until quite recently without any reasonable amount of success.

Among the earlier investigations may be mentioned those of Dupré and Dibdin[1] on the aeration of London Sewage, and those of the Massachusetts State Board of Health relating to the use of aeration in the filtration of sewage through gravel and sand filters. Dr. Drown,[2] chemist to this Board, concluded from the results of a series of experiments, that the oxidation of organic matter in water was not hastened by vigorous agitation with air.

Waring[3] of the United States was one of the first to apply aeration methods in the purification of sewage on a working scale.

In 1886 Hartland patented an aeration chamber for the purification of sewage or tank effluent, which Kaye Parry[4] employed in experiments undertaken in 1887, while in 1892 Lowcock conducted experiments on the aeration of filter beds by a forced air supply.

In the latter year Mason and Hine[5] published the results of a research on the aeration of mixture of sewage and water in which they concluded that aeration had but little oxidation effect on the sewage.

In 1897 Fowler[6] investigated the effect of aeration on the effluent resulting from the chemical precipitation of Manchester sewage, without any very tangible results being obtained, at any rate so far as the total amount of oxidation was concerned.

It would thus appear that the results of the earlier investigations on the subject of aeration of sewage, indicated that aeration *per se* could not be considered as a practicable adjunct in the process of sewage purification.

Recently, however, the subject has been reopened by the work of Black and Phelps, Clark, Gage and Adams, and Fowler and Mumford.

In dealing with the question of the pollution of the New York Harbour, Black and Phelps[7] studied the possibilities of the application of aeration to the treatment of sewage.

Their experiments dealt with the aeration of both fresh and partially septicised sewage, in various types of tanks and it was shown that under certain conditions it was possible by means of a reasonable amount of aeration to remove the more readily putrescible matters from the sewage and thereby to a certain extent increase its stability.

Black and Phelps were so far convinced of the practicability of such methods of treatment of sewage, as to recommend that the sewage from a certain section of the New York area should be dealt with on these lines, prior to discharge into the waters of the harbour.

In the Annual Report of the Massachusetts State Board of Health for the year 1912, published at the end of 1913, is described an investigation by Clark and De M. Gage on the possibilities of the use of aeration for preliminary treatment of sewage prior to filtration. They found that simple aeration of sewage for 24 hours reduced the free and albuminoid ammonia to some extent and that with sewage which was both aerated and seeded with green growths—*Protococcus* and *Scenedesmus*—the albuminoid ammonia was even more noticeably reduced. Later it was found that appreciable nitrification was obtained within 24 hours in the aerated sewage containing the green growths.

Subsequently Clark and Gage found that aeration for a much shorter period, in a tank containing slabs of slate about one inch apart, covered with a compact brown growth of sewage matters, was sufficient to coagulate the sewage colloids, and thus to produce a well clarified non-nitrified effluent capable of satisfactory filtration at several times the normal rate.

Later Fowler and Mumford[8] carried out experiments on the action in the presence of air, of an organism designated "M7" (isolated by Mumford from ponds receiving water discharged from a colliery) on sewage containing a certain proportion of iron salts.

This organism has the property of precipitating the iron as ferric hydroxide from solutions of iron salts.

In the paper referred to, it is stated that sewage (in presence of a certain quantity of iron salts) inoculated with this organism, can be thoroughly clarified by six hours aeration. The resultant effluent after settlement of the separated organic colloids, was quite clear and practically free from colloids. It is further stated that although the ordinary methods of analysis failed to reveal the extent of the change effected by the above treatment, the effluent after aeration was always non-putrefactive on incubation, and could be readily oxidised and nitrified by filtration at a high rate.

In quite a recent publication Clark and Adams[9] give the results obtained during 12 months operation of the specially constructed tank used in their earlier experiments previously referred to.

It is shown that a rather better coagulation of the organic colloids and purification of the sewage generally, can be obtained by means of aeration for a period of five hours, under the conditions of experiment, than is obtained by efficient chemical precipitation, and at a considerably reduced cost.

The effluent resulting from the aeration treatment was applied to trickling filters 10 feet deep, at rates varying from 8 to 10 million gallons per acre per day, with the production of a well-nitrified and thoroughly stable filtrate.

In connection with the experiments carried out by Clark and his colleagues, it should be mentioned that the sewage treated was considerably more dilute than the majority of English sewages, as will be seen from the following average analytical returns taken from the paper quoted.

	Parts per 100,000.
Oxygen consumed	3·52
Free and saline ammonia	3·62
Abuminoid ammonia	0·57

The researches of Clark, Gage, and Adams, and of Fowler and Mumford, show a marked advance on previous work, but it will be seen that in the case of the former investigators the idea of surface contact is retained, as evidenced by the construction of the aeration tank, and that in order to produce a nitrified and stable effluent, further treatment in filters is still required.

With regard to the method of treatment suggested by Fowler and Mumford, while the clarification is effected in the absence of surface contacts, the questions of inoculation and the addition of iron salts are introduced and the provision of filters for the rapid treatment of the clarified effluent remains.

In a previous communication to this section of the Society[10] in regard to the effect of the waste liquor from sulphate of ammonia plants on the oxidation of sewage, the present authors, in conjunction with Dr. Fowler, gave some results of the direct aeration of sewage.

It was noted that while some coagulation of the colloid matter took place in the course of twenty-four hours aeration, a period of several weeks elapsed before nitrification was complete.

In November, 1912, Dr. Fowler visited the States in connection with the question of the pollution of the New York Harbour. Shortly after his return he described to the authors a laboratory experiment which he had seen in progress at the Lawrence Experiment Station, Massachusetts, which evidently referred to the earlier work of Clark and his colleagues on the aeration of sewage in the presence of green organisms, as the bottle in which the sewage was aerated was coated inside with strands of algal growth. Dr. Fowler suggested that new work might with advantage be carried out on somewhat similar lines.

Acting on this suggestion, further investigations with regard to the subject of aeration of sewage, were undertaken by the authors.

An account of the results which have so far accumulated is given in the following paragraphs.

Preliminary experiments.

In a series of preliminary experiments, samples of Manchester raw sewage, contained in bottles of 80 oz. capacity, were aerated until complete nitrification ensued; the aeration being effected by drawing air through the sewage by means of an ordinary filter pump.

In the case of the first experiment, about five weeks' continuous aeration was required in order to obtain complete nitrification, as had been previously observed. At the end of this period the clear oxidised liquid was removed by decantation, and a further sample of raw sewage aerated in contact with the original deposited matter, until the sewage was again completely nitrified.

This method of treatment was repeated a number of times with the retention in each case of the deposited solids.

It was found that as the amount of the deposited matter increased, the time required for each succeeding oxidation gradually diminished until eventually it was possible to completely oxidise a fresh sample of crude sewage within twenty-four hours.

For reference purposes and failing a better term, the deposited solids resulting from the complete oxidation of sewage have been designated "activated sludge." Reference to its general characteristics, chemical composition and biological contents will be made later.

As a result of these preliminary experiments the following observations may be made:—

(*a*) In order that the final nitrification change may proceed without hindrance, it is necessary that the alkalinity or basicity of the sewage should be rather more

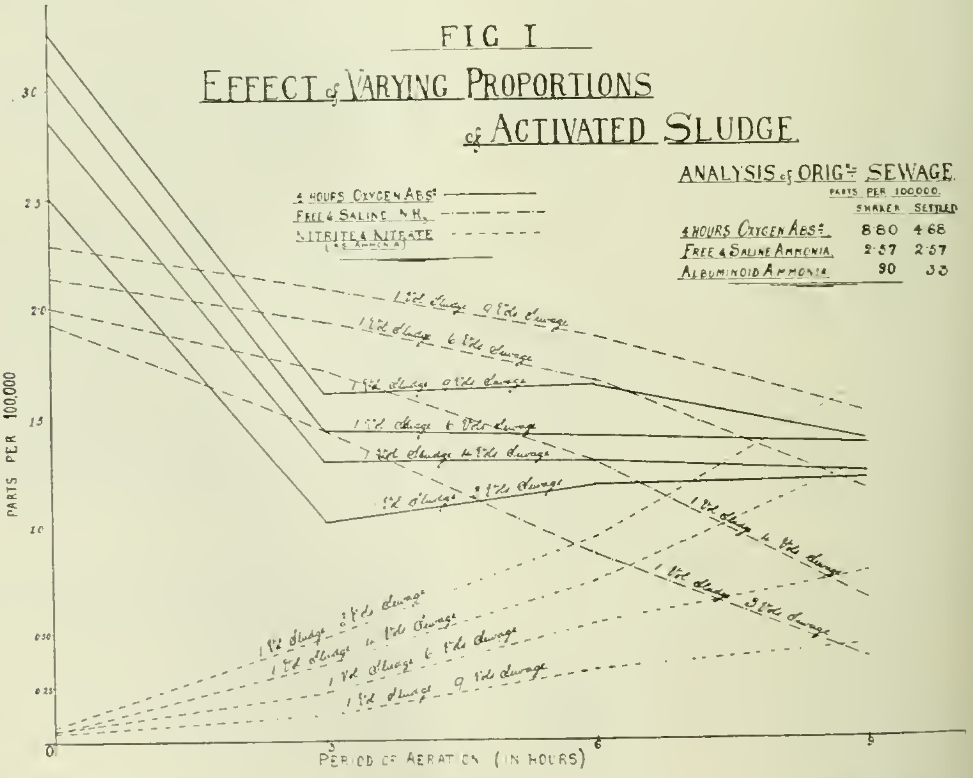

FIG I

EFFECT of VARYING PROPORTIONS of ACTIVATED SLUDGE

---

[10] This Journal, No. 10, Vol. XXXI., 1912.

than equal to the nitric acid resulting from nitrification of the ammonium salts. In some cases it has consequently been found necessary to add a small quantity of alkali prior to complete nitrification.

(*b*) It is essential that the activated sludge should be kept in intimate contact with the sewage during aeration.

This point is illustrated by an experiment, the results of which are given in Table I from which it will be seen that while the initial effect on the oxidisable matters as measured by the oxygen absorption test, is not materially affected, on further aeration a marked improvement is shown in the case where the activated sludge is kept in intimate contact with the sewage, than where such conditions do not obtain. Further, in regard to the amount of nitrification very much greater differences are to be observed. This is of considerable importance, as it will be seen from later experiments that the maintenance of the activity of the sludge is considerably influenced by the extent to which the oxidation is carried.

(*c*) That the relation of the volume of the activated sludge to the volume of sewage treated is of importance, more especially in regard to the rate of nitrification.

This latter point is clearly shown by the results of an experiment which was actually carried out much later on in the course of this investigation and which are given on Table Ia (p. 526) and plotted in Figure 1.

It will be seen from this table and diagram that while apart from the dilution effect, the reduction in the amount of oxidisable matter is not seriously affected by the varying proportions of activated sludge, the amount and rate of nitrification are influenced in a marked degree.

Oxidation of Manchester sewage.

Once having accumulated a sufficient volume of activated sludge in the manner previously described, a series of determinations were made of the effect of aeration in contact with the sludge, of various samples of the Manchester sewage received at Davyhulme.

In general a proportion of one volume of activated sludge to four volumes of sewage was taken, although in the earlier experiments a much smaller proportion of sludge was employed.

A number of typical results are recorded in Table 2. In each of the experiments quoted the samples of sewage taken are twenty-four hours average samples.

Reference to this table will show that an extraordinarily high degree of purification can be obtained within a reasonable period of time by aeration in contact with the activated sludge.

On the average, aeration under the conditions of experiment for a period of six hours, with subsequent settlement, is sufficient to obtain a percentage purification as measured by the four hours Oxygen Absorption and Albuminoid Ammonia Tests, quite equal to that yielded by efficient bacterial filters. In all cases the resultant effluent is non-putrefactive on incubation.

The amount of nitrification obtained during this period depends to a certain extent on the concentration or strength of the sewage dealt with. In several instances, when treating wet weather sewage, six hours' aeration has been found sufficient to completely oxidise the ammonia present (see Table 2, Expt. No. 30). With average strength Manchester sewage the free and saline ammonia content is entirely removed in from 10 to 18 hours' aeration.

It should be mentioned that all the experiments have been worked on the fill and draw method, and it may be reasonably anticipated that equally good results would be obtained with a less aeration period, when working on a continuous flow system.

Outdoor experiments are being commenced in which a continuous flow of a mixture of sewage and activated sludge will be passed through an aeration chamber.

Course of reaction.

In all cases it has been noted that there is a rapid initial effect on the oxidisable matters both colloidal, etc., and crystalloidal, with the production in a period of about three hours of a well-clarified effluent.

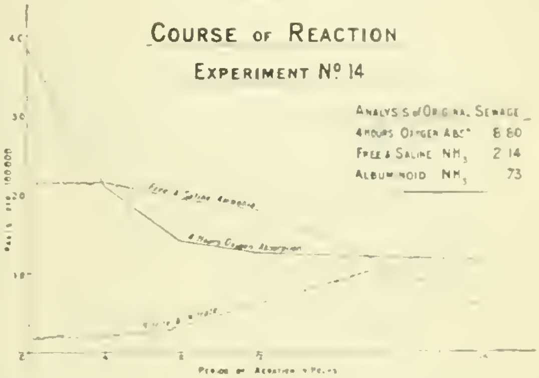
The later stages of the aeration are largely confined to the nitrification of the ammonium compounds.

In order to clearly illustrate this course of the reaction the results of an early experiment (see Table 2, p. 527, Exp. 14) are quoted, in which a small proportion only of activated sludge was employed, as in the later experiments with an increased proportion of sludge the first change occurs rapidly and consequently nitrification is established so early as to partially mask the course of the reaction.

The results of this experiment are plotted in Fig. 2 from which it will be seen that the purification change follows on the lines demonstrated by Adeney.

In view of this fact it was thought of interest to endeavour to sectionise the purification process into (*a*) a carbonaceous fermentation and (*b*) a nitrification process, with the idea of comparing the results with those obtained by the orginal method of working.

FIG II



Attempt to sectionise the oxidation process.

For the purpose of this experiment a partially activated sludge was taken, which while it was capable of effecting the first change, *i.e.*, the removal of the oxidisable matter did not actively promote nitrification.

Three large bottles were used.

(1) Containing a certain volume of this partially activated sludge (α sludge).

(2) (β sludge) and (3) ($\alpha\beta$ sludge) Containing a similar volume of thoroughly activated sludge which had been proved capable of vigorously promoting nitrification.

The experiment was carried out in the following manner. Equal volumes of the same sample of sewage were introduced into bottles Nos. 1 and 3 and aeration commenced. At the end of two hours' aeration the contents of bottle No. 1 were allowed to settle for two hours and the supernatant liquor was decanted into bottle No. 2. Another sample of sewage was then added to bottle No. 1 and aeration resumed. After a further two hours' aeration the contents of each of the bottles were allowed to settle for two hours.

In this manner an effluent was obtained from bottle No. 2 which had received two hours' aeration in contact with the partially activated (α) sludge and a further two hours' aeration in contact with actively nitrifying (β) sludge, and from bottle No. 3 an effluent which had been aerated for six hours in contact with thoroughly activated ($\alpha\beta$) sludge.

This method of operation was repeated as often as was reasonably practicable within the twenty-four hours, with the result that the partially activated sludge and nitrifying sludge (bottles Nos. 1 and 2) dealt with three volumes of sewage each working day, as compared with the two volumes treated by the thoroughly activated sludge.

The results obtained during the course of this experiment are given in Table 3 (p. 528).

Reference to this table will show that there was no very material difference in the effluents yielded by the two methods of working.

At the same time it will be seen that the results with the ordinary activated sludge show a marked deterioration as compared with those previously obtained, particularly in regard to the amount of nitrification.

* Original sewage diluted with a volume of water equivalent to the volume of sludge employed in the experiment.]

In the absence of any other altered factor this decreased efficiency might reasonably have been ascribed to the fact that while in the previous experiments any particular sample of sewage was always aerated in contact with the activated sludge for from 20 to 24 hours to ensure complete nitrification, in the present case, at the end of first six hours' aeration the purified liquor was replaced with a further sample of sewage.

Unfortunately, however, during the course of this series of experiments, low temperatures were experienced, not only with the sewage dealt with, but also in the laboratory, owing to trouble with the heating apparatus.

It was thus impossible to say to what extent, if any, either of these two factors influenced the results obtained, and instead of continuing sectionised experiments on these lines, attention was diverted to the study of the questions involved.

Before leaving this part of the subject it may be stated that while the above experiment failed to determine the possibilities of sectionising the oxidation process the matter has not been lost sight of, and it is the intention of the authors to return to this question at an early date.

Maintenance of Sludge Activity.

In order to determine how far the purification effect of the activated sludge was influenced by not carrying the oxidation process to complete nitrification the following experiment was carried out.

Activated sludge of known efficiency was divided into four equal volumes and placed into separate bottles, viz., A. B. C. and D. each of four litres capacity and containing a sample of the same sewage.

The following procedure was then adopted :—

Bottle A.—Sewage aerated for six hours in contact with activated sludge, followed by two hours' settlement, sample of purified effluent taken, remaining contents of bottle aerated for 14 to 16 hours longer.

Bottle B.—Sewage aerated in contact with activated sludge for ten hours, sample taken at end of six hours.

This operation was repeated twice during the twenty-four hours.

Bottle C.—Sewage aerated in contact with activated sludge for six hours, sample taken and purified effluent removed as in A. Sludge was then aerated for the remainder of the day.

Bottle D.—Sewage aerated for six hours in contact with activated sludge, followed by two hours' settlement and subsequent removal of purified effluent by decantation.

This operation was repeated three times during the twenty-four hours.

It will be seen that with similar aeration the sludge in bottle D. dealt with three volumes of sewage to two volumes in case of bottle B. and one volume in the case of bottle A., while the sludge in bottle C. also only dealt with one volume of sewage, but the amount of air required for aeration was reduced by the fact that for from 14 to 16 hours the sludge alone was aerated.

A series of results obtained during the course of this experiment are given in Table 4 (p. 528).

The results of the first experiment of this series (Experiment 54) are given in order to show that the activity of the sludge in each case was identical. As the experiment proceeded, while the oxidation effect as measured by the oxygen absorption test differed only slightly according to the method of working, a marked difference was observed in the amount of nitrification. In the case of the sludge contained in Bottle A., which only dealt with one sample of sewage per day, the nitrification was maintained as in the first experiment, but in each of the other methods of working the nitrification was seriously impaired, in fact almost inhibited.

It was observed, however, that the sludge in Bottle C. after the removal of the oxidised effluent, had not been well aerated during the period of working. Accordingly means were adopted to improve this aeration. The results obtained during the second and third week's working, of which typical examples are given (Experiments 59—66) show that the effect of this improved aeration was to maintain the activity of the sludge and consequently to yield similar results to those obtained when the whole of the sewage and sludge was aerated for 22 hours.

It will be seen that the results obtained with the sludge contained in Bottle D. gradually deteriorate with the total inhibition of nitrification. In the case of the sludge in Bottle B. the falling off in its activity was not so marked, although the nitrification was considerably reduced.

It is evident from the results of this experiment that the activity of the sludge is gradually diminished, when working on the fill and draw method, if it is called upon to treat further samples of crude sewage, prior to the complete nitrification of the previous sample dealt with.

The results also show that this difficulty may be overcome by simple aeration of the sludge alone, until the free and saline ammonia content is removed.

Influence of Temperature.

In order to determine the influence of temperature on the oxidation process a series of experiments extending over several weeks were carried out on the aeration of Manchester sewage in contact with activated sludge at temperatures varying from 5°—30° C. A number of typical results are given in Tables 5, 6 and 7 (pp. 529—531).

It should be mentioned that in all the experiments quoted in this section of the work, the activated sludge dealt with one volume only of sewage per day. Samples were taken after three, six and nine hours' aeration respectively and then aeration was resumed until the next dose of sewage was treated.

It was found that the oxidation process could be maintained within a fairly wide range of temperature. At temperatures constantly below 10° C. a very marked deterioration in the results was observed, especially with regard to the removal of the colloidal matters. Also nitrification was practically inhibited within a period of nine hours' aeration. It is fairly evident that this effect would be accumulative over a prolonged period of working with the probable eventual production of inactive sludge.

At temperatures varying from 12—14° C., which is the usual air temperature of the laboratory, the activity of the sludge was well maintained with the production at all times of a satisfactory effluent.

It was further observed that with a temperature of 20° C. equally good results were obtained as regards the removal of the oxidisable matter and clarification effect, with an increase in nitrification during the later periods of aeration.

Working with temperatures as high as 30° C. it was found that the initial clarification effect was to some extent interfered with and that the effluent resulting from subsequent settlement showed a slight deterioration as compared with that obtained when working at tempera- tures from 12—20° C. This effect became less marked as the aeration continued and once nitrification was establishe it proceeded at a slightly increased rate as compared wit that obtained at temperatures below 20° C.

Oxidation of various sewages.

It was thought of interest to compare the results obtaine with Manchester sewage, which contains an undue pr portion of a variety of trade effluents, with those of mor purely domestic sewage.

Samples of sewage were therefore obtained from th following sewage works :—

(a) Moss Side Sewage Works	Urmston
(b) Withington Sewage Works	Chorlton
(c) Gorton Sewage Works	Gorton
(d) Macclesfield Sewage Works	Prestbury.

In view of the difficulty of obtaining average rep sentative samples of sewage from the above works, it w decided to work with samples of maximum strength, i. in each case the samples were taken in the afternoo and consequently this fact must be borne in mind considering the results which are given in Tables 8 and

In connection with these results attention should drawn to the following :—

(*a*) *Moss Side sewage.*

Experiments on this sewage were carried out in earlier part of the investigation and consequently proportion of activated sludge to the sewage treated was considerably less that in the later experiments. Further in order to more clearly demonstrate the actual oxidation effect of the activated sludge in the control experiment the sewage aerated alone was diluted with a volume of tap water equal to that of the sludge employed in the experiment. The analytical figures given for the shaken sample of sewage refer to the sample actually taken plus the diluting water.

Sample A.

This was a Monday afternoon sample, and obviously contained an excessive amount of soapy matter. It will be seen from the table that this soapy matter exerted a considerable emulsification or deflocculation effect as shown by the increase in the four hours' oxygen absorption and albuminoid ammonia of the "original" settled sample after mixing with the activated sludge, and in consequence of this effect the results obtained were not so striking as the previous ones, although considerable nitrification was obtained within six hours. It would appear that in the case of sewages containing undue proportion of soapy matter, preliminary treatment with lime might be advantageously employed.

Sample B.

It will be seen from the analytical returns that this was a stronger sewage than the preceding one, but contained less soap. In this case no preliminary emulsification was observed and a much greater purification was effected in the earlier stages of aeration.

(*b*) *Withington sewage.*

The sewage from the Withington works was considerably weaker than that received from the Moss Side works and consequently as would be anticipated, complete oxidation ensued within a greatly reduced period of aeration. It may be noted that two hours' aeration in contact with activated sludge, with subsequent settlement was sufficient to produce an effluent which was non-putrefactive on incubation.

(*c*) *Gorton sewage.*

It is evident from the analysis given in Table 9 that the sample dealt with was an exceedingly strong sewage. With three hours' aeration a remarkable change was effected as measured by the usual tests. After six hours' aeration an extremely well clarified effluent was obtained, but unfortunately owing to an accident it is not possible to give the chemical analysis.

Despite the highly concentrated nature of this sewage 9 hours' aeration was sufficient to yield an entirely satisfactory effluent showing a rather higher percentage purification on the raw sewage than that which is yielded by efficient bacterial filters. Within a period of 9—18 hours the whole of the free and saline ammonia was removed from the sewage.

(*d*) *Macclesfield sewage.*

The sample of Macclesfield sewage was very turbid and was said to contain waste refuse of a mucilaginous character derived from silk works. With this type of sewage the oxidation proceeds satisfactorily although the percentage purification effected is not quite so good as in the case of Gorton sewage. A well clarified effluent was obtained with six hours' aeration in contact with activated sludge and subsequent settlement. The whole of the free saline ammonia was removed within a period of sixteen hours.

Quality of effluents.

It has frequently been observed that effluents obtained from the oxidation process, while having a comparatively low oxygen absorption as measured by the permanganate test and a low albuminoid ammonia content, may absorb an undue proportion of dissolved oxygen on incubation for a number of days. When once the free and saline ammonia content of an effluent is very considerably lowered even without material alteration in the four hours' oxygen absorption and albuminoid ammonia figures, the amount of dissolved oxygen absorbed by the effluent is enormously reduced. It would thus appear that the stage to which nitrification has advanced is one of the factors governing the amount of dissolved oxygen absorbed by an effluent. Experiments are in progress with a view to throwing further light on this subject, but the data so far available is insufficient to allow of any definite conclusions. It is quite certain however, that in the effluents obtained, the amount of oxygen absorbed from permanganate bears no relation whatever to the amount of dissolved oxygen absorbed.

Activated sludge.

Activated sludge accumulated in the manner previously described is quite inoffensive, dark brown in colour and flocculent in character, and despite its low specific gravity separates from water or sewage at a rapid rate. After prolonged settlement the activated sludge however rarely contains less than 95 per cent. of water.

A remarkable separation of the water from the sludge can be readily obtained by treatment on fine grade strainers with the production of a sludge of the consistency of a stiff jelly.

Gelatine counts have shown a bacterial content of at least 30 million organisms per cubic centimetre. In addition, the sludge by reason of its nitrifying power must of necessity contain a large number of nitrifying organisms.

It should also be noted that a fairly large number of a variety of protozoa are to be found and we are indebted to Mr. James Crabtree for assistance in regard to the enumeration and identification of these higher forms of life. It does not however contain any algal growths.

The chemical analysis of an average sample of the activated sludge is as follows :—

	Percentage.
Organic matter	64·7
Mineral matter	35·3
Total nitrogen (N)	4·6
Phosphate (P_2O_5)	2·6
Matter extracted by CCl_4	5·8

Attention should be drawn to the abnormally high percentage of nitrogen as compared with ordinary unoxidised sewage sludge.

Nature of reaction.

Up to the present the authors have not seriously investigated the actual mechanism of the process and consequently no attempt has been made to differentiate between the part played by physical, chemical and biological agencies, all of which are doubtless, in varying degrees responsible for the total purification change. As to whether the protozoa content has any influence or not on the extent of the purification has yet to be determined, although it would appear that they rather indicate a particular condition of the activated sludge than play an important part in the changes effected.

While as previously stated no serious attempt has been made to determine to what extent bacterial agencies are concerned with the purification process, an experiment has been made on the effect produced by the aeration of sewage in contact with activated sludge both before and after steam sterilisation.

The results of this experiment are given in Table 10, from which it will be seen that activated sludge when sterilised under these conditions had no purification effect whatever (see p. 533).

It must be borne in mind, however, that the physical characteristics of the activated sludge may be seriously altered by the steaming process and consequently some other method of sterilisation, *e.g.*, by means of ultra-violet rays might yield somewhat different results.

Summary and Conclusions.

The foregoing investigations have established :

1. That the resultant solid matter obtained by prolonged aeration of sewage, which has been termed activated sludge, has the property of enormously increasing the purification effected by simple aeration of sewage, or in other words it greatly intensifies the oxidation process.

2. The extent of the accelerating effect depends upon the intimate manner in which the activated sludge is brought into contact with, and upon its proportion to, the sewage treated.

3. That in order to maintain the sludge at its highest efficiency it is necessary that there should not be at any time an accumulation of unoxidised sewage solids.

It is not necessary that the sewage should be kept in contact with the activated sludge until such conditions obtain, as its activity may be maintained by suitable aeration of the activated sludge alone.

4. That temperature exerts a considerable influence on the oxidation process. The purification effected is seriously diminished at temperatures constantly below 10° C. Up to 20—24° C. no material difference in the clarification effect and general purification has been observed although the nitrification change proceeds more rapidly as the temperature rises. At higher temperatures the clarification effect is somewhat interfered with during the earlier period of aeration, with a consequent delay in the establishment of nitrification. Subsequently the rate of nitrification somewhat increases.

5. That under the conditions of experiment a well oxidised effluent can be obtained by the aeration of average strength Manchester sewage in contact with activated sludge for a period of from six to nine hours. The percentage purification effected as measured by the usual tests is at least equal to that obtained by the treatment of sewage on efficient bacterial filters.

The period of aeration naturally depends upon the strength of the sewage treated and the degree of purification required.

6. That the activated sludge differs very considerably in character and composition from ordinary sewage sludge.

It is in a well oxidised condition and consequently entirely innocuous, can be readily drained on straining filters and possesses a high nitrogen content.

The scope of this inquiry has been up to the present largely confined to laboratory investigations and while the results obtained have shown conclusively that the purification process can be readily maintained, a large amount of further research is required in order to obtain a thorough knowledge of the character and mechanism of the changes taking place, which will be essential for the efficient control of the process.

The method employed in producing a satisfactory purification of sewage is however of so simple a nature, that there would not appear to be any insuperable difficulties in translating the experiments described, on to a working scale.

In view of the obviously great reduction in the area of works required and capital expenditure involved, the available data in regard to the probable cost of aeration is such as to lend encouragement to the idea that the adoption of aeration methods on the lines of these experiments would result in a considerable reduction in the total cost of sewage purification. In this connection it may be reasonably anticipated that the enhanced value of the resultant sludge should at least cover all costs incidental to its disposal.

In conclusion the authors wish to express their sincere thanks to Dr. Fowler for the suggestion which originated this inquiry, and for the keen interest with which he has followed the whole series of experiments.

They are indebted to the Rivers Committee of the Manchester Corporation for permission to publish the results of this investigation, which has been carried out in the laboratory at the Corporation Sewage Works, Davyhulme.

Discussion.

Dr. J. Grossman said that the sludge question had entered upon a phase in which, though it was not expected to produce a large profit, it was to a certain extent capable of commercial treatment. Where the present processes of purification might be barred by local circumstances the process described in the paper if successful would be greatly in advance of what was being done at present. No doubt, in some instances it would become a commercial question as to whether aeration by means of activated sludge would be more economical than any of the other processes of purification and the mechanical element would enter very largely into this question. He had been very much struck with the amount of nitrogen in the sludge. Was this partially due to the elimination to a greater extent of the detritus matter than was usual with ordinary sludge? Perhaps the authors could give them some information as to the average amount of nitrogen in ordinary Manchester sludge. Assuming even as much as two per cent. of nitrogen on the dry sludge then the 4 or 4½ per cent. of nitrogen shown could not be accounted for by a larger quantity of detritus having been taken out. Even if they took into consideration the ammonia being utilised by the bacteria, he could not understand how an increase of nitrogen could be obtained because the bacteria were supposed to oxidise the ammonia into nitrates which were soluble, unless the bacteria took up the nitrogen from the air and used it for building up their own bodies which afterwards remained in the sludge.

Mr. F. R. O'Shaughnessy regarded the paper as an epoch-making one, provided that the process experimentally established by the authors could ultimately be applied on the large scale at a reasonable cost. After all, from the point of view of the man-in-the-street—the man who paid the rates—the financial question was one of the first questions. The process suggested by the authors would greatly reduce the area of the works and would probably go far to eliminate nuisance, and these too were very important considerations from the public point of view. In Germany sewage was often merely precipitated or sedimented and the sewage liquor then pased through open channels for many miles to the nearest river. The Germans seemed to have no objection to this, but in England such a procedure would not be tolerated.

Apart, however, from such general and practical considerations, the scientific interest of the paper could not be over-estimated. So far as he could judge, the main principle at work did not differ substantially from that which obtained in an ordinary bacteria bed, viz., exposure to the necessary organisms in presence of an excess of oxygen. The experiments demonstrated that there must be considerable surface contact between the liquor to be purified and the "activated" sludge. The action was undoubtedly a very complex one. Merely physical effects in the way of flocculating the colloidal and finely divided suspended solids would be obtained which would help in clarifying the liquor. The destruction of the colloidal character of the sludge was no doubt brought about by biological agents and it was interesting to note that at a temperature of 30° C. a process of deflocculation went on

Recently he had read a paper before the Institute o Sanitary Engineers giving a number of observations bearin on these points. Many engineers apparently held th view that the so-called "colloiders" precipitated colloida matter by virtue of their physical action. This vie was erroneous, for these "colloiders" were efficient onl because they provided a habitat for the micro-organism which were the effective "colloiders." Not till th sewage liquor had an enormous surface presented to i as in a bacteria bed, did physical forces remove an appreciable quantity of impurities from the liquor. Th great advantage inherent in the process outlined by th authors of the present paper was that aerobic conditio prevailed and foul products were thereby eliminate

His observations on these phenomena extended ov many years and the following figures which were th averages of many analyses over a lengthy period made the Birmingham sewage under working conditions on th large scale were correspondingly very reliable. I had taken the "oxygen absorbed in four hours" figu on the liquor freed from visible suspended solids as index as to what happened This figure for the cru sewage liquor was 17·10 parts per 100,000, and aft passing through a plain rectangular sedimentation ta where the time of sojourn was four to five hours the liqu then gave the figure 13·71. A remarkable point w that 20 per cent. of the dissolved impurities were remov by this simple means. Further treatment of the liqu for six hours in a septic tank reduced the figure to 12· After that the liquor passed through a five-mile-long sew and the above figure was reduced by a six hours sojourn in this sewer to 9·11 parts per 100,000. The surface to which the liquor was exposed in this sewer was very considerable and the colloidal matter was precipitated to an appreciable extent on this journey, whilst the suspended matter was correspondingly increased. This suspended matter was arrested in upward flow conical tanks and the figure for the clear liquor issuing from these tanks fell from 9·11 (above) to 8·71 parts per 100,000. Passage through a percolation bed then reduced the figure to about two parts per 100,000 in ½ to 1 hour.

If the above observations were set out as rates per hour of elimination of impurities in solution the result became very striking. These rates were as follows :—

On the sedimentation tank	0·68	parts per hour.
,, ,, septic ,,	0·20	,, ,, ,,
,, ,, five-mile sewer	0·70	,, ,, ,,
,, ,, upward flow tank	0·28	,, ,, ,,
,, ,, percolation bed, about	10·00	,, ,, ,,

The total purification of dissolved oxidisable impurities by 22 hours tank treatment was about 50 per cent. and was greater under "septic" than under "non-septic" conditions.

In another set of experiments on the large scale the sewage was divided into two portions each portion passing through two separate sets of tanks. One portion was treated with two parts per 100,000 of bleaching powder and the other untreated. The chlorinated liquor was sterilised by the treatment, and no change took place in the figure for "oxygen absorbed" owing to passage through the tanks, whilst on the other hand an appreciable drop in the dissolved oxidisable impurities occurred in the liquor passing through the other set of tanks to which no bleaching powder had been added. These observations had a bearing on the process brought forward by Messrs. Ardern and Lockett, for they threw some light on the nature of the action. Broadly, his conclusions were that the grosser colloidal matters held by sewage iquors came down readily in ordinary continuous flow sedimentation tanks, that the great bulk of the colloidal matters—say 70—80 per cent—were held very tenaciously by the sewage liquor and were only removed by either biological agents, or physical forces suitably applied uch for instance as in a well constructed and properly worked bacteria bed. In ordinary modern works practice probably the biological factors were the most potent, and he experiments carried out by the Authors indicated that his held good with respect to the new process they desribed.

One other point he wished to refer to was the part played y the nitrogen in these phenomena. He agreed with he authors that this behaviour was rather puzzling, nd much work remained yet to be done on this most mportant aspect of the question.

Mr. S. E. Melling thought the process described was deal inasmuch as it resolved itself into a single-tank treatment. The greatest bugbear to the sewage problem had een the question of sludge disposal. By means of the w system the sludge, activated in the manner described, came the friend rather than the enemy of the sanitary ientist. Had there been any estimation of the perntage of nitrogen during the different stages of the velopment of activity of the sludge it would be teresting to learn by what stages the fixation of the trogen took place. He observed that the carbon tetraloride extract was put down as grease. Had any proximate examination been made of that extract, as would be distinctly against the value of the sludge a manure if the grease was left in ? The whole scheme peared to be one of great value for communities with ry small available spaces of land at their disposal. it was possible to have the carbonaceous fermentation ried out successfully in a preliminary tank, whether was in the nature of a "roughing" tank or filter, or ilar existing device, and so bringing the effluent to the ge where, by passing it through aerating-filters the essary nitrification could be attained, a great saving uld be effected. The filters could be fed four to six es their usual speed. An interesting point occurred connection with the disappearance of nitrogen, where in some cases the oxidised product did not at all correspond with the free ammonia. According to one of the tables shown it would seem that the best dilution for the oxidation-cycle to proceed, regularly and completely, was 1 : 12. Might there not be some feasible explanation of the loss of nitrogen when the ratio of activated sludge to sewage was much higher ?

Mr. Percy Gaunt said that the method of treatment suggested might offer advantages sufficient to compensate for any additional power required for the aeration process, in view of the reduced area required, and the possibility of reduction of the nuisance from smell and from flies. Under the present system, even when circumstances favoured a fairly compact scheme, an area of ten acres would usually be required for the disposal works of a town of about 40,000 inhabitants, when due allowance had been made for the selection of a site providing the fall of several feet, necessary for a filtration process. The experiments described suggested the possibility of reducing the area by about eighty per cent., and the necessary fall to a few inches. A suitable site under existing conditions might be two or three miles from the town, entailing an independent power installation, whereas with the reduced area and diminished fall requirements of the suggested method, full advantage might be taken of any cheap power (such as a town gas, or electricity supply) in choosing the position of the works. Interesting information as to the relative importance of the physical and biological factors in purification might be obtained from comparative aeration experiments conducted (a) under ordinary conditions ; (b) in the presence of ultra-violet rays.

Mr. Johnson inquired whether the sludge contained any ammonia, and also what quantity of air was required.

Mr. J. T. Thompson said that one striking feature of the new process was that it was aerobic from beginning to end, and it was probable that the amount of smell would be negligible. If these laboratory results could be economically obtained on a large scale the present elaborate system of dealing with sewage would be simplified ; the cost of pressing sludge, depositing it in the sea or in trenches on land would be avoided, for activated sludge evidently dries rapidly and would yield good manure. This process might also reduce the area of bacteria beds needed. What volume of air was it necessary to blow through the mixture, for this would be a costly item in practice ? He presumed there would be some limit below which the sludge would not be sufficiently mixed with the supernatant liquid to complete the oxidation in a reasonable time. With regard to the high nitrogen figure in the activated sludge, if possible, he would like to have an analysis of ordinary Manchester sludge to compare with the sample of activated sludge.

Mr. Hart (Leeds), speaking as an engineer, thought the process would resolve itself into a question of the relative cost of manipulation of the sludge either as liquid or solid matter. He admitted that the difficulty from the engineering side at the present time was to find a satisfactory method of manipulating the sludge for useful manurial purposes at a reasonable cost. At the moment he could not see that there was a probability of there being any great saving in costs of manipulation. The present experiments were, however, laboratory experiments, and it would be necessary to deal with sewage and sludge in bulk before any reliable data could be furnished as to cost.

Dr. G. J. Fowler said that a considerable time ago Mr. Ardern and himself read a paper before the Society on suspended matter in sewage and effluents, which raised in a simple way a question which had found its final expression in the paper they had heard that night, that was to say the flocculation of colloidal matter. The end had not been reached at once. There had been a number of stages, and a great many minds had been at work on the question. When he had the honour of delivering the Chairman's address before the Section he mentioned the idea of Dr. Maclean Wilson of an enzyme which might clot out sewage and produce the effect which now took place in a percolating filter, and ventured to suggest that it might be possible to find something of the kind. An experiment was tried with some of the deposit from a filter, blowing it up in sewage, with apparently little result. Other chemists had tried the same experiment. It was only right to admit that the illuminating idea which originated the work was really due to a visit he had paid while in the United States, to the Mecca of sewage purification, namely, the experimental station at Lawrence in the State of Massachusetts, where he saw the bottle, described in the paper, in which sewage had been completely purified by 24 hours' aeration. The idea at that time, and subsequently in the experiments which had been published from that laboratory, involved the principle of surface. He discussed some of the possibilities of the method with the President of the New York Sewerage Commission, and that gentleman was of the opinion that the idea of surface should be abandoned if possible if the matter was to be really advanced. They also discussed the question of the clarification of sewage. The problem at New York was to deal with some 1,000 million gallons of sewage per day and the idea of sprinkling such a large quantity about in the atmosphere in the hot American summer did not seem to be altogether practicable. In the intervening time other experiments had been made by Mr. Mumford and himself with regard to the clarification of sewage bacterially, and they had succeeded in clarifying altogether about 10,000 gallons by means of a process which had already been published. As Dr. Grossmann had observed, local conditions had to be taken into consideration. It was also necessary to consider the process of sewage purification on the one hand and the utilisation of the nitrogen and other constituents on the other. The process described in the paper aimed at purifying the sewage as rapidly and as simply as possible. He, for his own part, believed that the process was practicable on a large scale, and they would have some idea of what that meant when he mentioned that the settling tanks at Davyhulme were constructed to hold 21 millions gallons. The results indicated in the paper showed that some six hours' blowing would produce an effluent equal to the final effluent at present obtainable; that was to say, complete purification in six hours. Assuming that the operation was only carried out twice in the 24 hours, allowing six hours to blow and six hours for the manipulation Mr. Hart had spoken of, aerating the sludge and so forth, it meant that in the tanks available 42 million gallons per day could be purified. The consequent saving of space and expenditure on filters would be something enormous, and would allow for quite a large expenditure on power and otherwise for the provision of air. He would not commit himself to figures that evening. It would not be a wise proceeding at that stage. The question of cost had been very carefully considered, and the whole matter had been approached from a number of points of view. Estimates had been obtained for large scale-work in blowing and so forth. He had consulted Mr. S. L. Pearce, the Chief Engineer of the Manchester Corporation Electricity Department, with reference to the amount of power required for providing a certain amount of air, estimating for the greatest quantity of air conceivable for the purpose, and recent work which had been begun showed that there had been an over-estimation in that direction. Taking everything together he was convinced that the process was a practical proposition. In order to carry it out by the most economical method possible it was, of course, necessary to call in the aid of their friends the engineers. Figures as to cost had been published by experimenters in America. In a paper by Messrs. Clark and Adams, published in the "Engineering Record," the figure for electricity was placed at 2d. per unit, which was not very cheap, and on that basis the cost of air was given at 8s. 4d. per million gallons. The American sewage was rather dilute. There was also cost of the slate surfaces. Still, if it was possible to carry on the process at the cost of 8s. 4d. per million gallons the matter appeared to be quite practicable. It was necessary to get the principle right in the first place, and on that point he had no doubt. The idea was really nothing new in a way. All that was happening was that instead of running the stream of sewage over a filter bed with imperfectly oxidised sludge one took activated sludge and moved it about with complete aeration. In the same way that a percolating filter was a concentration of land treatment so the treatment described was a further concentration on the percolating filter. No really new principle was involved, and for that reason it appeared to him the thing was on right lines. Regarding the question of nitrogen which had been raised, his view was that the organisms collected a certain amount of nitrogen from the products present in solution and built up a certain amount of protoplasm thereby. He was confirmed in this opinion by experiments made at the Manchester University, where a deposit was obtained containing even more nitrogen than was indicated in the paper. The amount of mineral matter in activated sludge was not high. It would be necessary in order to secure success that very careful means be taken to remove the grit, and considerable engineering skill would be required to design really satisfactory grit chambers. There were no such things in existence in the world at the present time, but no doubt the problem was capable of solution. The complete removal of grit would materially assist the working of the process. The research work carried out by Messrs. Ardern and Lockett opened out possibilities which would re-awaken the public interest in the sewage problem, which, perhaps, to some of them had latterly become somewhat of a bore by being standardised to such an extent that the whole question had become one of routine. The Authors of the paper had now fired a bombshell into the camp, and perhaps they would all start on new ways in the future.

Mr. Ardern, in reply, said that no means had been taken to remove the detritus from the sewage which was generally the average 24 hours' sample. An inspection of the analysis would show that the percentage of organic matter in the resulting sludge was 65 per cent. or thereabouts, whereas the usual percentage of mineral matter in sedimented sludge in the case of Manchester would be about 50 per cent., so that there was a considerable increase in the organic content. With regard to the high percentage of nitrogen, the figure given was the mean of several determinations. It would appear that the high nitrogen content was due to a large extent to the flocculation of the fæcal emulsion. There had been no determinations of nitrogen at different stages of the accumulation of the sludge. There were still a number of points requiring elucidation, and it was not suggested that investigation had been made into every operation tha actually took place. What had been done was to endeavou to obtain results which could be readily maintained unde conditions in which apparently there should be no seriou difficulty in translating to a practical working scale. Th scientific side of the matter had only been dealt with in limited manner. The authors agreed with Dr. Fowle in regard to the principle of the process which he ha dealt with in the course of his remarks. As stated by M O'Shaughnessy, with a temperature of 30° Cent. there wa apparently a slight deflocculating action on the sludge, b it was not maintained, the effect being observable in t initial stages, flocculation subsequently occurring. N examination had been made of the grease extract, as at t time the determination was made the activated slud was rather a valuable product from the experiment point of view. He was of opinion, however, that t percentage of fatty matter present was not sufficient militate against the use of the sludge as a fertiliser. was a considerably lower percentage, as Dr. Grossma would be aware, than in the case of ordinary sewa tank sludge, even counting the whole carbon tetrachlori extract as grease. It was quite common for ordina tank sludge to contain 10 to 15 per cent. of grease extra and possibly in some cases a greater quantity. There no definite explanation to offer in connection with loss of the nitrogen, and there was no doubt that w regard to the conservation of that constituent furt information was required. In the earlier experime almost quantitative nitrification of ammonia was obtai This did not apply to the later experiments where t was a greater loss of nitrogen. It may be mentio that during the later experiments a greater volum sludge was employed, and nitrification proceeded more rapid rate which might possibly have some influ on the liability to losses of nitrogen. The question of effect of waste liquor from sulphate of ammonia pl had not been investigated. The Manchester se dealt with, however, contained from 0·5 to 1·0 per cent. of this trade effluent, and in this proportion no serious retarding effect on the oxidation process was apparent. If, as appeared probable, the process was essentially bacterial, there was no doubt that any serious amount of inhibiting matter, of whatever type, as long as it was bactericidal, would doubtless have to some extent a deterrent effect. The volume of air required was a point which obviously was connected with the cost of the aeration process. They had not gone very deeply into the matter. As a matter of fact the laboratory experiments had been aerated without consideration of the question of cost. They had determined the volume of air used in the experiments, which was evidently much in excess of that actually required; the quantity amounting to something about one-fifth of a cubic foot per square foot of tank area per minute. While Dr. Fowler naturally refrained from giving any figures, one could say without hesitation that the quantity of air required was very much less than that allowed in any calculations he had made. In the laboratory experiment the air was used not only for aeration but also as a means of agitation, and it was quite conceivable that a combination of mechanical agitation with the use of air for aeration purposes only would be more economical. That, of course, remained to be seen. A question had been raised as to the effect of grease, concerning which he could not give any information. Whatever grease there was in the average sample was in the sewage when they treated it, and there was no apparent hindrance to the oxidation process. At no time was there an excessive quantity of grease, but he was of opinion that some simple means would be adopted for removing any actual grease from the sewage before subjecting it to any such treatment.

The main feature of the experimental work was the satisfactory purification of sewage by tank treatment alone, with the production of a sludge which, owing to its oxidised and flocculent condition, could be readily dealt with and converted into a valuable fertilising agent.

A number of samples illustrating the experiments of the authors were exhibited.

Obituary.

HERMAN FRASCH.

Herman Frasch was born in Gaildorf, Würtemberg, in 1851. In 1868 he went to America and soon attained the foremost position in the Laboratory of Prof. Maisch of the Philadelphia College of Pharmacy. In a short time, however, he turned his attention to chemical industry, and acting quite independently, he commenced a series of investigations bearing upon the subject of petroleum and its products. In 1876, at the age of twenty-four, Frasch evolved a process for refining paraffin wax, which so pleased the directors of the Cleveland Petroleum Company, that they purchased it, and the young chemist was induced to leave Philadelphia and go to Cleveland, and make the petroleum industry his speciality. Numerous patents were now taken out by him. These were not all confined to petroleum and its products, for in 1882, he patented a process for making white lead directly from galena, and between 1882 and 1886 one for making sodium carbonate from salt by the ammonia process, besides others in connection with practical applications of thermo-electricity. In the works of the Empire Oil Company, Frasch solved the problem of purifying the offensive sulphurised petroleum oils of Canada and Ohio, thus raising them to a high degree of purity. In 1888, the Standard Oil Company bought his patents after exhaustively testing their value. One of Frasch's greatest achievements was his ingenious process for recovering the sulphur from a huge deposit in Louisiana, 1000 feet down in the earth and covered by dense layers of sand. Heat was applied to the sulphur *in situ* by means of superheated water forced down a boring, first fusing and then impelling the melted sulphur up an inner tube to the surface (see this J., 1912, 168—169). He applied for 10 patents for processes and apparatus in this connection. Now, thanks to Frasch's inventive genius, sulphur (formerly shipped from Sicily to America), is exported in large quantities from America to Europe. Frasch ultimately became President of the Union Sulphur Company of New York and Hamburg, and of the International Sulphur Refineries of Marseilles. Two years ago, at a Meeting of the New York Section of this Society, Prof. Chandler, in presenting to him the Perkin Gold Medal of the associated Chemical and Electrochemical Societies, said, the " Perkin Medal Committee felt fully justified in placing Mr. Frasch by the side of William H. Perkin, as one of our greatest industrial chemists and chemical engineers."

He died May 1st, 1914, in Paris, at the age of 63.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows; Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris 3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

Patents.

Taking samples of powdered or liquid substances; Apparatus for ——. T. Roberts, Bolton. Eng. Pat. 7354, March 28, 1913. Addition to Eng. Pat. 23,237 of 1911.

Various mechanical devices for controlling the sampling device of the apparatus described in the chief patent, and clockwork mechanism for operating the controlling device are claimed.—W. H. C.

Determining by weight quantities of gas, steam or other vapour or liquid; Process and apparatus for ——. G. A. H. Binz, Enfield. From C. A. Hartung, Berlin. Eng. Pat. 8042, April 5, 1913.

The resistance for varying the measuring current in proportion to the flow of the fluid in the measuring apparatus described in Eng. Pat. 27,357 of 1911 (this J., 1913, 74) is placed in the circuit before it branches to the resistance bridge, and the resistances which serve to correct for variations of pressure and temperature are placed in the branches of the bridge itself.—W. H. C.

Ovens [for ores, etc.]. C. Dressler, Marlow, Bucks. Eng. Pat. 8505, April 10, 1913.

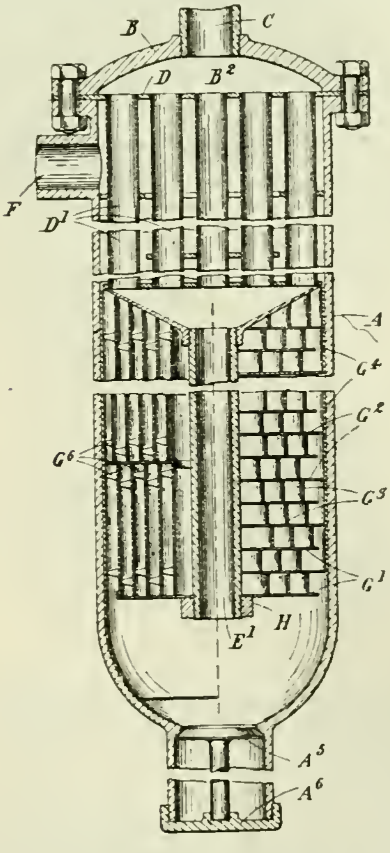
An oven of the type described in Eng. Pat. 8228 of 1912 (this J., 1913, 792) is so constructed that the interior of the combustion chamber (or chambers) is not in communication with the interior of the oven, and the cooling zone is provided with two or more conduits. Air or air and heating gases are passed through the conduits on their way to the combustion chamber, thereby serving as cooling media and, at the same time, being preheated. The conduits may be arranged one within another. The ends of the ovens may be normally closed, and the oven wall provided with inlets and outlets for the gases to be introduced.—F. Sodn.

Calcining and roasting furnaces. E. Cornet. Fr. Pat. 465,302, Nov. 25, 1913.

A column roaster or calciner provided with two grates, the lower to support the calcined or roasted product and the upper to support the charge. Air is admitted through a central conduit which extends upwards to about the middle of the charge and has a conical grid above and lateral openings as well. The kiln is also provided with a telescopic chimney the bottom portion of which can be lowered into the throat of the kiln. The grate bars are manipulated by levers.—W. H. C.

Retorts for treatment of fluids. C. V. Boys, London. Eng. Pat. 8803, April 15, 1913.

The retort, which is used for submitting liquids, gases or vapours to the action of heat, either alone or in the presence of a catalytic agent, is made in one piece and has a cover, B, at the upper end, and a valve, A^5, and cap, A^6, at the lower end for the removal of any deposit. The fluid to be treated enters the retort at C, passes downwards through a regenerative system of tubes, D^1, and a central conduit, E^1, and then upwards through a series of spiral passages and around the tubes, D^1, to the outlet, F. The spiral passages are formed by open scrolls of metal, G^3, arranged between the two series of alternate baffle-plates, G^1, G^2, as shown at the right-hand side of the figure, the fluid thus passing radially inwards and outwards in successive scrolls. When the plates, G^1, G^2, are wide apart as shown at the left-hand side of the figure, the scrolls are of corresponding depth and are spaced apart by tongues, G^6, stamped out from them. The plates G^1, G^2, and scrolls, G^3, may be made of a suitable metal to act as catalytic agent, the plates, G^2, then having flanges, G^4, which form a lining for the retort. The whole of the parts within the retort form an insertion which is supported from the tube-plate, D^1, and can be lifted out through the top of the retort. If the insertion becomes choked or jammed in the retort, the nut, H, is removed from below, the regenerator and pipe, E^1, lifted out and the scrolls and baffle-plates removed separately.—A. T. L.



Still or retort. S. E. Kelsey, Kansas City, Mo. U.S. Pat. 1,092,366, April 7, 1914.

The retort is fixed in a furnace and has an outlet port near the top. It is partly filled with molten material in which a number of baffles are floating. The material to be treated is delivered through a pipe into the lower part of the molten mass.—W. H. C.

Settling tanks. W. Loebel, Leipzig, Germany. Eng. Pat. 19,597, Aug. 29, 1913.

A settling tank is provided with curved baffles, guide plates, or deflectors extending from the inlet to near the outlet, to cause the liquid entering the tank to take a downward course before it rises to the outlet. Means are provided for removing sludge from the bottom of the tank. —W P. S.

Drying and mixing miscellaneous materials; Machine for ——. N. Ammann. First Addition, dated Nov. 3, 1913, to Fr. Pat. 453,614, Jan. 27, 1913 (this J., 1913, 780).

The closing device for the outlet end of the drying cylinder is formed of two concentric overlapping cones connected together by helical ribs. The interiors of the cones are also provided with helical blades. This device allows hot gases to enter the drying cylinder through the passage between the cones, whereas the dried material is prevented from escaping through this passage but is directed to the outlet end of the outer cone.—W. H. C.

Chemical reactions between solids and gases; Process for effecting ——. Soc. Générale des Nitrures. Fr. Pat. 465,242, Jan. 31, 1913.

In carrying out the process described in Fr. Pat. 462,464 (this J., 1914, 302), the gas is passed through the reaction chamber at a reduced speed, by causing it to leave or to enter and leave through the permeable walls of the chamber.—W. H. C.

Solids suspended in liquids; Process and apparatus for the extraction of —— in the form of mud. L. Hertenbein. Fr. Pat. 465,323, Nov. 26, 1913.

The mixture is fed into a tank in which a drum filter is rotated partially immersed. The periphery of the drum is formed of a number of separate arc-shaped filter chambers the outer surfaces being covered with filtering material and the interiors connected by two radial pipes and the hollow shaft with a vacuum pump and with a supply of compressed air, so that those filter chambers which are immersed in the liquid are under vacuum and those above the liquid under pressure. The filter-cake is loosened by the compressed air and removed by a roller working against the upper surface of the drum.—W. H. C

Absorption vessel with tangential gas-inlet tubes. H. Flasche. Ger. Pat. 271,786, March 21, 1913.

At the lower part of the vessel, just above the ends of the tangential gas-inlet tubes, is an annular hood provided with slots. The gas issuing from the tubes causes a vigorous circulation of the liquid below the hood, and the liquid above the hood is gradually drawn through the slots and intimately mixed with the incoming gas.—A. S.

Drying plastic materials; Method of —— and apparatus therefor. O. Eberhard, Heidenau, Germany. Eng. Pat. 8068, April 5, 1913.

See Fr. Pat. 455,959 of 1913; this J., 1913, 933.—T. F. B.

Drying machine; Centrifugal ——. A. Cassirer, München, Germany. Eng. Pat. 12,914, June 4, 1913.

See U.S. Pat. 1,087,528 of 1914; this J., 1914, 312.—T.F.B.

Drying-kiln; Continuous —— with vertical axis. J. Réol, Assignor to Soc. de Constructions Mécaniques d'Alais, Alais, France. U.S. Pat. 1,093,206, April 14, 1914.

See Eng. Pat. 16,262 of 1912; this J., 1913, 816.—T. F. B.

Gaseous mixtures; Process and apparatus for the separation of —— into their constituents. R. P. Pictet, Berlin-Wilmersdorf, Germany. Eng. Pat. 9357, April 21, 1913. Under Int. Conv., July 2, 1912.

See Fr. Pat. 457,031 of 1912; this J., 1913, 1108.—T. F. B.

Filter-press. C. W. Merrill, Berkeley, Cal. U.S. Pat. 1,093,345, April 14, 1914.

See Fr. Pat. 431,106 of 1911; this J., 1912, 16.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Methane; The lower limits of inflammation of —— with mixtures of oxygen and nitrogen. A. Parker. Chem. Soc. Trans., 1914, **105**, 1002—1007.

The lower limits of methane in mixtures of oxygen and nitrogen in various proportions in which self-propagation of the flame upwards took place indefinitely after the original source of ignition was removed, decreased from 5·99 per cent. of methane in oxygen to a minimum of 5·76 per cent. in a mixture of oxygen 25 and nitrogen 75 per cent. Further decrease of the oxygen content to 13·25 per cent. produced a marked rise in the lower limit. In air the smallest percentage of methane required to produce continuous propagation of the flame was 5·77, and a reduction of 4 per cent. in the oxygen content only raised the limit 0·2 per cent., so the reduction of the percentage of oxygen in the air of mines would hardly minimise the possibility of firedamp explosions.—G. F. M.

Gaseous mixtures; Ignition of —— by the electric discharge. H. F. Coward, C. Cooper and J. Jacobs. Chem. Soc. Trans., 1914, **105**, 1069—1093.

The inflammability of various gaseous mixtures was compared by determining the lowest pressures at which the mixtures could be ignited with a given sparking arrangement. Mixtures of oxygen and hydrogen were more inflammable as the proportion of oxygen was increased up to 70 per cent. Electrolytic gas at a pressure somewhat too low for ignition, became inflammable by adding, without change of volume, either oxygen, hydrogen, nitrogen, carbon dioxide or argon. Experiments were also made with mixtures of oxygen with carbon monoxide, cyanogen, methane and ethylene respectively, and with various diluents in each case. Two important factors governing the ignition were the thermal conductivity of the mixture and the energy degraded when the spark was passed; in the case of mixtures of carbon monoxide (moist) with oxygen and diluents, a third important factor was the "activation" of oxygen by the discharge. —A. T. L.

Oil gas; Manufacture of ——. A. E. Forstall. J. Gas Lighting, 1914, **125**, 511—512.

The improved Jones apparatus consists of a primary generator and a secondary generator communicating at their lower ends, each containing two superposed chambers partly filled with chequer-brickwork, through which the gases or vapours pass downwards. The gases or vapours from the lower end of the primary generator pass upwards through additional chequer-brickwork in the lower part of the secondary generator to the gas outlet which is common to both generators. In operation, the brickwork is heated first by blowing with air, which burns away the soot formed during the previous gas-making period, and then by admitting oil to burners placed in the lower of the two chambers of each generator. The temperature is raised to 1800°—2100° F. (982°—1149° C.) at the top of the primary generator and 1800° F. (982° C.) in the secondary generator. Gas making is then commenced and continued until the temperature falls to 1200° F. (649° C.). During gas making, oil-gas from the process is passed through the apparatus as well as steam, in order to dilute the oil vapours and reduce the amount of lampblack formed.—A. T. L.

Oil-gas produced in the Jones apparatus; Analyses of ——. L. B. Jones. J. Gas Lighting, 1914, **126**, 319. (See preceding abstract.)

The oil-gas contained CO_2, 3·6; C_6H_6, 0·9; C_nH_{2n}, 4·9; O_2, 0·2; CO, 9·4; H_2, 38·3; CH_4, 37·8; and N_2, 4·9 per cent., and had a calorific value of 686 B.Th.U. per cb. ft. The quantity of oil used was 7·2 galls. per 100 cb. ft. of gas, and 44 per cent. of the carbon contained in the oil passed into the gas.—A. T. L.

Nitrogen; Recovery of —— as ammonia, from coal. J. W. Cobb. J. Gas Lighting, 1914, **126**, 329—331.

The experiments of Burgess and Wheeler (this J., 1914, 191) on the slow distillation of bituminous coal in a vacuum showed that the greatest yield of ammonia per grm. of coal was obtained at about 550° C. Christie noticed that very little ammonia was produced below 500° C. or above 800° C. and that by slow distillation at 500°—700° C., about twice as much ammonia could be obtained as in the usual coke-oven or gas-retort practice. At 700° C., when equilibrium is attained, a mixture of nitrogen, hydrogen, and ammonia at atmospheric pressure contains only 0·022 per cent. NH_3, and a gas containing H_2 50, N_2 5, and NH_3 1·2 per cent., if left in contact with the charge in the retort at 800° C, would lose practically all of the ammonia by decomposition. Hence it is necessary to produce the ammonia at the lowest possible temperature and to remove it from the retort as soon as formed. In laboratory experiments at 800° C., when the gas was removed at once from the hot part of the tube, 22·5 per cent. of the nitrogen of the coal was obtained as ammonia; when the gas passed through a red-hot part of the tube before exit, 17·2 per cent.; and when the gas passed through red-hot coke, 9·4 per cent. When a current of carbon monoxide, carbon dioxide or nitrogen was passed over coke at 800° C., little or no ammonia was obtained from the nitrogen in the coke; with dry hydrogen, 10 per cent. of the nitrogen was liberated as ammonia; and when water vapour, alone or mixed with hydrogen, was used, nearly the whole of the nitrogen was obtained as ammonia. The conditions approximate to this in the Mond producer, in which 60—70 per cent. of the nitrogen is recovered. Producer gas or coke-oven gas which has been well scrubbed for the extraction of ammonia is specially suitable for regenerative working on a continuous system without reversals, because it is free from dust and does not choke the narrow conduits.—A. T. L.

By-product coking in Canada. Chem. Trade J., May 9, 1914. [T.R.]

According to the official figures for 1913, published by the Canadian Department of Mines, the total output of oven coke in the Dominion during the year was 1,517,133 tons of 2000 lb., made from 2,147,913 tons of coal, of which 1,598,912 tons were mined in Canada, and 549,001 tons imported. The total quantity of coke sold or used by the producers during the year was 1,530,499 tons, valued at 5,547,694 dols. In 1912 the total output was 1,406,028 tons, and the quantity sold or used by the producers, 1,411,229, valued at 5,164,331 dols. By-products from coke ovens recovered during the year included 10,608 tons ammonium sulphate. 8,371,600 gallons of tar, and 3,353,731 thousand cubic feet of gas, and the total value would approximate 866,150 dols. At the end of the year there were 1720 ovens in operation, and 1325 idle.

The exports of coke during 1913 were 68,235 tons, valued at 308,410 dols; and the imports 723,906 tons, valued at 2,180,830 dols. In 1912 the exports were 57,744 tons, valued at 252,763 dols.: and the imports 628,174 tons, valued at 1,702,856 dols.

Determination of sulphur in spent oxide by combustion. Somerville. *See* VII.

Development of dry cleaning in blast-furnace gas purification. Müller. *See* X.

An adiabatic calorimeter. Gray. *See* XXIII.

PATENTS.

Coal and like fuel; Compound for treating ——. J. H. Harris, London. Eng. Pat. 18,705, Aug. 18, 1913.

A MIXTURE of sodium chloride 53, sodium carbonate 33, and aluminium silicate 4 parts, and water is sprinkled over the coal. Chlorine is liberated when the coal is burned and assists the combustion.—W. H. C.

Vertical retorts; Method and apparatus for discharging carbonised products obtained in ——. J. G. Aarts, Dongen, Holland. Eng. Pat. 17,612, July 31, 1913. Under Int. Conv., Aug. 1, 1912.

THE descending mass of coke passes from the retort into an enlarged chamber below, and is divided vertically into two or more portions by a reciprocating saw. It then comes in contact with a set of spiral cams exerting an intermittent knocking off and picking action delivered from the centre outwards.—W. H. C.

Coal-gas and coke; Method of manufacturing ——. W. P. Parsons, Flushing, N.Y. U.S. Pat. 1,092,950, April 14, 1914.

COAL is distilled in retort chambers relatively long and high, the walls of which are inclined at an angle slightly greater than the angle of repose of the coal, so that the mass is subject to a nearly uniform pressure during distillation, due to its own weight. The chambers are heated uniformly by means of flues in the walls.—A. T. L.

Gas producers. W. Hart, Sydney, New South Wales. Eng. Pat. 8126, April 7, 1913.

To obtain tar-free power gas from wood and light waste fuel without the use of a wet scrubber, a producer is employed in which the air for combustion enters at both top and bottom of the fuel column, the gas outlet being midway. The fresh fuel is partially distilled in a large chamber above the upper air inlets, which are arranged around the throat connecting this chamber with the producer shaft and are inclined downwards. There are cooling and dust-collecting chambers at either side of the producer, the whole being enclosed in a rectangular casing. The gases from the producer pass through one set of cooling chambers, then through an annular re-heating chamber around the lower part of the producer shaft, and finally through the second set of cooling chambers and a chamber packed with cocoanut fibre.—A. T. L.

Gas producers, coal distillation retorts, etc. W. Anderson, Helensburgh, J. Meikle, Glasgow, and C. W. Fulton, Paisley. Eng. Pat. 11,712, May 20, 1913.

COAL is delivered continuously to the top of the fuel column by means of a screw conveyor arranged horizontally in a pocket in the vertical walls of the retort or producer, and coke or ash is removed continuously from the bottom of the retort or producer through a water-seal by means of an inclined screw conveyor. The conveyors are of the type described in Eng. Pats. 4446 of 1912 and 12,521 of 1913.—A. T. L.

Gas producer apparatus; Suction ——. P. T. Houston, London. Eng. Pat. 15,367, July 3, 1913.

THE producer is specially suitable for marine propulsion, and provides a supply of steam for auxiliary purposes during gas-making and also when gas is not required. A coking chamber for the fresh fuel is disposed above the producer chamber, the whole being enclosed in a water-jacket forming a steam-boiler provided with the usual fittings. The upper part of the coking chamber is provided with air inlet nozzles and forms a combustion chamber for burning the gases and vapours distilled from the fresh fuel. The crown of this chamber is connected with the top plate of the boiler by vertical tubes through which the combustion products pass. The coke formed in the coking chamber descends into the producer chamber, from which producer gas free from tar is drawn off for use in the main engines. When gas is not required, the level of the fuel may be near the producer grate, the apparatus then working simply as a boiler.—A. T. L.

Water-gas; Apparatus for generation of ——. J. Stephenson, Salisbury. Eng. Pat. 15,677, July 7, 1913.

To repeat automatically the desired cycle of operations, as described in Eng. Pats. 6849 of 1911 and 26,916 of 1912 (this J., 1912, 377; 1913, 971), the valves, etc., controlling the process are actuated by solenoids and electric motors controlled by contacts on a rotating drum. The operating circuits are closed by contacts on the drum and broken at some other point by the movements of the parts operated.—A. T. L.

Gas producers. W. Dodd, Oldham. Eng. Pat. 29,381, Dec. 20, 1913.

IN a producer in which steam is generated in a coil or chamber arranged in the upper part, and is led beneath the grate, water is fed through a trapped pipe to the steam pipe leading from the coil to the ash-pit.—A. T. L.

Coal gas; Process for the purification of —— *from hydrogen sulphide and cyanogen.* C. A. Bergh. Ger. Pat. 272,094, March 19, 1912.

A SOLUTION of a zinc salt, containing also ferrous chloride, is used as absorbent, and to neutralise the free acid formed, a quantity of an insoluble or sparingly soluble substance, preferably calcium carbonate, corresponding to the total quantity of hydrogen sulphide and cyanogen, is added, gradually or all at once, so that zinc sulphide and cyanide are precipitated either fractionally or together, whilst the iron remains in solution. By this method the waste lyes from copper extraction processes can be utilised, and in a single operation the separation of zinc from iron and of hydrogen sulphide from cyanogen effected.—A. S.

Hydrocarbons; Making lighter —— *from heavier ones.* Planes, Ltd., Birkenhead, and W. P. Thompson, Liverpool. Eng. Pats. 5245 and 21,273, March 1 and Sept. 20, 1913.

HYDROGEN or purified water-gas is passed through petroleum heated under a pressure of 5 to 100 lb. per sq. in. in the presence of finely-divided nickel, immersed in the liquid. The gases and vapours are separated from unchanged petroleum in the cooler parts of the still and then passed through a reducing valve to a purifier containing finely-divided nickel and finally to a condenser. The petroleum is freed from sulphur and asphaltum before use, on account of their harmful effect on the catalyser.
—A. T. L.

Mineral oil; Manufacture of products from ——. The New Oil Refining Process Ltd., London, and E. L. Lomax, Preston, Lancs. Eng. Pat. 10,040, April 29, 1913.

The gaseous products obtained in cracking hydrocarbon oils are passed through sulphuric, phosphoric, telluric, or selenic acid; from the floating mixture of oils obtained, the paraffins are recovered by distillation with steam in the presence of alkali. Unsaturated siccative oils are recovered from the residual alkaline solution by extraction with a solvent, and from the acid liquid by diluting it with water.—O. E. M.

Crude oil; Process for treating ——. W. S. Barnickel, St. Louis, Mo. U.S. Pat. 1,093,098, April 14, 1914.

Crude petroleum containing not less than 10 per cent. of water and slimy substances emulsified with the oil, is thoroughly mixed with iron sulphate solution, the quantity of sulphate not exceeding 1 per cent. of the impurities. On standing, the oil, slime, and water form separate layers, and the oil can be drawn off.—A. T. L.

Coke ovens; Regenerative ——. E. G. A. Lecocq, Brussels. Eng. Pat. 10,253, May 1, 1913. Under Int. Conv., May 13, 1912.

See Fr. Pat. 457,674 of 1913; this J., 1913, 1000.—T. F. B.

Coke ovens. Gebr. Hinselmann, Essen-Ruhr, Germany. Eng. Pat. 29,069, Dec. 16, 1913. Under Int. Conv., Jan. 13, 1913.

See Ger. Pat. 268,327 of 1913; this J., 1914, 411.—T. F. B.

Vertical retorts; Apparatus for discharging ——. H. Koppers, Essen on Ruhr, Germany. Assignor to H. Koppers Co., Chicago. U.S. Pat. 1,093,936, April 21, 1914.

See Eng. Pat. 29,371 of 1912; this J., 1913, 860.—T. F. B.

Illuminating and fuel gases from wood; Process of manufacturing ——. R. M. Poole, Mount Gambier, South Australia. U.S. Pat. 1,093,470, April 14, 1914.

See Eng. Pat. 13,929 of 1913; this J., 1914, 190.—T. F. B.

Asphalte-like masses and derivatives therefrom; Process for the manufacture of ——. L. Landsberg, Nuremberg, Germany. Eng. Pat. 8069, April 5, 1913.

See Fr. Pat. 457,054 of 1913; this J., 1913, 1000.—T. F. B.

Process of generating hydrogen. U.S. Pat. 1,092,903. *See* VII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Peat, Treatment of —— by wet-carbonisation. N. Testrup and M. A. Atkinson, London, T. Rigby and G. W. Andrew, Dumfries, and Wetcarbonizing Ltd., London. Eng. Pat. 2283, Jan. 28, 1913.

Wet peat is subjected to wet-carbonisation, for example as described in Eng. Pats. 17,610 of 1911 or 25,146 of 1912 (this J., 1912, 1171; 1914, 346), the liquid matter is separated, neutralised with alkali, and concentrated in an evaporator, which may be of the type referred to in Eng. Pats. 12,462 and 22,670 of 1911 (this J., 1912, 971; 1913, 183). The vapours evolved during evaporation are washed with acid liquor to extract the ammonia, before they are returned to the heating surfaces of the evaporator. The concentrated liquor, or the solid evaporation residue, is mixed with peat fuel from the process and gasified in an ammonia-recovery gas producer. The proportion of the nitrogen in the wet peat passing into the liquor during wet-carbonisation may be increased by raising the temperature. In one case, the proportion was 19 per cent. at 180° C., but only 14 per cent. at 170° C.—A. T. L.

Ammonia contained in semi-solid materials [e.g. peat]; Process and apparatus for the recovery of ——. E. Stauber and W. Kochan. Fr. Pat. 464,227, Oct. 29, 1913.

An apparatus for the recovery, as ammonia, of the nitrogen contained in peat and similar substances by destructive distillation. Carbonisation is effected in a vertical retort into which the material is charged from a feed hopper, the latter having slots in its sides communicating with an annular flue surrounding the retort. In the lower part of the carbonising chamber is a system of tubes through which water is circulated; the steam developed serves to actuate an ejector in the gas-outlet main, whereby gases are exhausted from the retort and directed to a condenser where the ammonia is recovered, the uncondensable gases being returned and burned in the annular flue surrounding the retort and thus supplying some of the heat required for the carbonisation and for drying the raw material in the feed hopper. Steam from the water tubes may also be directed on to the incandescent charge in the carbonising chamber to increase the yield of ammonia. —A. S.

Wood distillation; Process and apparatus for ——. F. Woidich, Prague-Weinberge, Austria-Hungary. U.S. Pat. 1,092,620, April 7, 1914.

The gases from the retort pass through a collecting main in which they are brought into contact with tar and so become saturated with tar oil vapours. The saturated gases are then cooled to the dew point of the higher-boiling tar oils, and brought into intimate contact with the tar from which the oil has been removed; the oil vapours remaining in the gases are absorbed by the tar, which is then separated in a tar extractor.—W. H. C.

Arc light electrode. F. M. Lewis. Ger. Pat. 271,993, July 3, 1913.

A chromate is added to the known mixture consisting chiefly of tungstates and fluorides, which is applied to arc light carbons to improve their light-emitting and burning properties.—A. S.

Peat; Removal of water from wet carbonised ——. N. Testrup, London, and D. Söderlund, Clapham Park, Assignors to Wetcarbonizing, Ltd., London. U.S. Pat. 1,094,270, April 21, 1914.

See Eng. Pat. 4684 of 1911; this J., 1912, 323.—T. F. B.

Arc-electrode and process for making it. J. L. R. Hayden, Schenectady, Assignor to General Electric Co., New York. U.S. Pat. 1,093,182, April 14, 1914.

See Eng. Pat. 2027 of 1909; this J., 1910, 264.—T. F. B.

Electrode [for arc lamps]. E. Weintraub, Lynn, Mass., Assignor to General Electric Co., New York. U.S. Pat. 1,093,957, April 21, 1914.

See Eng. Pat. 11,792 of 1912; this J., 1913, 415.—T. F. B.

Table photometers. Eng. Pat. 1239. *See* XXIII.

III.—TAR AND TAR PRODUCTS.

Patents.

Oils of the petroleum, tar and similar types; Apparatus for distilling ——. L. Steinschneider, Brünn, Austria. Eng. Pat. 8758, April 14, 1913.

The apparatus is for distilling oils under a high vacuum. The gases from the still are drawn through a tube condenser, and then through a liquid seal to the barometric condenser and vacuum pump. By varying the depth of the seal, the degree of vacuum in the still can be adjusted as desired. The oil condensed in the tube condenser passes through a cooling coil to a vessel connected with the vapour conduit leading to the barometric condenser, so that the vapours given off from this distillate are withdrawn. This vessel is connected with the distillate pump and has a branch-pipe through which the distillate can be passed directly to the receiving tank instead of through the pump.—A. T. L.

1-*Chloro-anthraquinone; Process for preparing nitro and chloro derivatives of* ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,681, Aug. 12, 1911. Addition to Ger. Pat. 267,544 (see this J., 1914, 70).

NITRO-ANTHRAQUINONESULPHONIC acids or anthraquinonedisulphonic acids or their salts are heated with thionyl chloride. Sulphochlorides are obtained as intermediate products, from which sulphur dioxide is eliminated, with the formation of the corresponding nitrochloro or dichloro derivative.—T. F. B.

Sulphonaphthylated aromatic p-diamines; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,821, March 14, 1911.

AN aromatic *p*-diamine is condensed with an aminonaphthalenesulphonic acid, with or without addition of a solvent or suspending agent. The products appear to consist mainly of the monosubstituted compounds of the type, $NH_2.R.NH.C_{10}H_6.SO_3H$, which are valuable azo dyestuff components; the disulphonaphthyl derivatives are only produced in small quantity.—T. F. B.

IV.—COLOURING MATTERS AND DYES.

Sulphur; Action of —— *on amines. Part II. Aniline.* H. H. Hodgson and A. G. Dix. Chem. Soc. Trans., 1914, **105**, 952—956.

THE resinous mass which is the chief product of the action of sulphur (25 grms.) on aniline (50 grms.) and aniline hydrochloride (25 grms.) at 185°—190° C. for 3 to 4 hours, consists largely of trithioaniline $S_3(C_6H_4.NH_2)_2$. This was isolated as its sulphate by extraction of the mass with hydrochloric acid, addition of sulphuric acid, and precipitation by gradual addition of aqueous caustic soda solution (yield 71 grms.). On diazotisation and combining with the usual components it yielded dyestuffs possessing good fastness. The hydrochloride and a crystalline oxalate and benzoyl derivative are described. —G. H. F.

1.2.3.4.-*Tetrachloroquinizarin.* H. Hövermann. Ber., 1914, **47**, 1210—1213.

CONTRARY to the statement in Ger. Pat. 172,105, tetrachlorophthalic acid can be condensed with quinol under suitable conditions. When the constituents are heated to 195°—230° C. with boric acid, dihydroxybenzoyltetrachlorophthalic acid is first formed, and this is converted into 1.2.3.4.-tetrachloroquinizarin by heating the boric acid melt with concentrated sulphuric acid to 150°—165° C. The product dissolves in alkalis with a cornflower-blue colour and does not dye on the ordinary mordants. Heating to 250° C. with lime water and copper powder converts it into dichlorotetrahydroxyanthraquinone, in which the newly introduced hydroxyl groups probably occupy α-positions. This product dyes on mordants in shades similar to those of Brazil wood. Tetrachloroquinizarin reacts with *p*-toluidine to give 2.3.4-trichloro-1-*p*-toluidinoquinizarin, which is soluble in alkalis with a dark blue-violet colour.—J. B.

Carminic acid. C. and H. Liebermann. Ber. 1914, **47**, 1213—1219.

A CRITICISM of the recent work of Dimroth and his collaborators (Annalen, 1913, **399**, 1, 43, 62), arguments being deduced against the conclusion that carminic acid is an anthraquinone derivative, namely methylhydroxyanthraquinonecarboxylic acid. The solubility of carminic acid in water is without parallel amongst the hydroxyanthraquinones, except as glucosides or sulphonic acids. There is no parallel in the anthraquinone series for the peculiar behaviour of carminic acid in yielding water when heated above 145° C. with formation of a water-insoluble dyestuff, which cannot be reconverted into carminic acid. The yield of anthracene hydrocarbons obtained by the distillation with zinc dust is very small. A new derivative of carminic acid, the anhydride, $C_{22}H_{20}O_{12}$, has been obtained by the action of thionyl chloride. It is a red powder, insoluble in water and alcohol, and it can be reconverted into carminic acid by the action of alkali, differing in this from anhydrocarminic acid.—J. B.

Osage Orange; The value of —— *as a dyestuff.* F. W. Kressmann. Textile Colorist, 1914, **36**, 97—98.

THE dyestuff of the wood of the Osage Orange tree appears to be composed of morin and maclurin, as in the case of fustic. The extractive matter is almost identical with that of fustic in quality and quantity, and the 25,000 tons of mill waste produced annually in the United States might under certain conditions compete with fustic.—J. B.

Isocurcumin; Synthesis of an ——. G. Heller. Ber., 1914, **47**, 887—890.

VANILLIN was condensed with acetylacetone in presence of alcoholic hydrogen chloride, yielding a mixture of substances from which a product isomeric with curcumin was isolated. This so-called isocurcumin appears to consist of a mixture of stereoisomerides.—J. R.

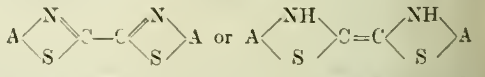
PATENTS.

Colouring matters of the anthracene series; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin u. Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat 10,291, May 1, 1913.

THE products obtained by treating acetylamino-anthraquinones with acid chlorides (see Eng. Pats. 29,750 of 1906 and 9657 of 1907; this J., 1907, 1135; 1908, 556) are converted into deep red-brown to yellow-brown vat dyestuffs by treatment with dehydrating agents, for example sulphuric acid. The reaction may also be brought about by more energetic treatment with acid chlorides themselves, in which case it is possible to start directly from the acetylamino-anthraquinone or even from the aminoanthraquinone, the acetylation and the two steps of the reaction being performed in one operation. The reaction is complete when no further change takes place on heating the product with 97 per cent. sulphuric acid at 160° C. for two hours.—J. B.

Colouring matters of the anthraquinone series; Manufacture of compounds and ——. J. Y. Johnson, London. From Badische Anilin u. Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 21,027, Sept. 17, 1913.

VAT dyestuffs dyeing generally lemon-yellow shades and having the probable constitution



where A represents an anthraquinone residue, are produced by treating an *o*-halogen-acetylaminoanthraquinone with sulphur or a substance capable of yielding sulphur, or alternatively by treating an *o*-aminoanthraquinone mercaptan with a compound capable of introducing the oxalic acid residue, *e.g.*, oxalyl chloride.—J. B.

Acridones and thioxanthones of the anthraquinone series, Process for preparing ——. Badische Anilin und Soda Fabrik. Ger. Pat. 272,297, Feb. 7, 1913.

oa'-DIHALOGENANTHRAQUINONYLARYL ketones are treated with sulphamides, sulphides, or sulphydrates, or analogous

Compounds, preferably in presence of a diluent, a catalyst, and a substance which will combine with acid.—T. F. B.

Azo dyestuffs ; Production of new ——. P. A. Newton. From Farbenfabriken vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 10,380, May 2, 1913.

DISAZO dyestuffs dyeing cotton red to brown shades which become fast to washing and light by after-treatment with formaldehyde are formed by combining tetrazotised diaminodiphenylureas with one mol. of resorcinol and one mol. of an aminonaphtholsulphonic acid or a derivative thereof, *e.g.*, 2.8.6-, 2.5.7-, or 1.8.4-aminonaphtholsulphonic acids or their acetyl, benzoyl, or imidazole derivatives.—J. B.

Purpurincarboxylic acid ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 272,301, March 11, 1913. Addition to Ger. Pat. 260,765.

1.4-DIHYDROXYANTHRAQUINONE-3-CARBOXYLIC acid is used in place of 1.2-dihydroxyanthraquinone-3-carboxylic acid in the process described in the principal patent (see Eng. Pat. 29,506 of 1912 ; this J., 1913, 593). The first product of the oxidation appears to be 2-hydroxyanthradiquinone-3-carboxylic acid ; by prolonging the fusion, or by adding a reducing agent, or by pouring the melt into aqueous bisulphite solution, it is converted into the known 1.2.4-trihydroxyanthraquinone-3-carboxylic acid.—T. F. B.

Disazo dyestuffs ; Process for preparing mordant ——. Anilinfarben- und Extract-Fabr. vorm. J. R. Geigy. Ger. Pat. 271,445, Jan. 19, 1913.

THE disulphonic acids of thioaniline or of *p*-diaminophenyl ether are diazotised and combined with salicylic acid or *o*- or *m*-cresotinic acid. The products give yellow dyeings on wool, which are fast to potting and milling after chroming. They may also be used for printing cotton goods on account of their solubility and ease of fixation and the fastness of their chrome lakes.—T. F. B.

Anthraquinone derivatives containing sulphur ; Process for preparing ——. Chem. Fabr. Griesheim-Elektron. Ger. Pat. 271,947, June 5, 1913.

ANTHRAQUINONE-IMINES which do not contain substituents in the o-positions to the imino-group necessary for the formation of *p*-thiazines, are treated with sulphur chloride or solutions of sulphur in sulphur chloride. The products are *p*-thiazines of the anthraquinone series ; some of them are vat dyestuffs whilst others are easily converted into vat dyestuffs.—T. F. B.

Triphenylmethane dyes ; Process for the production of ——. Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 19,488, Aug. 28, 1913. Under Int. Conv., Aug. 30, 1912.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Pyrites ; Seleniferous —— *and its use in the manufacture of sulphite pulp.* J. C. Torgersen and C. Bay. Papierfab., 1914, 12, 483—484.

SELENIUM is always present in iron pyrites in proportions, relatively to the sulphur, ranging from 1 per 10,000 to 1 per 100,000. On roasting, the selenium is volatilised as selenium dioxide, but is finally found in the acid as elementary selenium. Under certain circumstances much harm may be done. Experiments in practice with two varieties of pyrites, both containing the same quantity of selenium, but one a dusty sort and the other free from dust, proved that it is not directly the presence of selenium which causes trouble but the simultaneous presence of dust. With very dusty sorts of pyrites it is impossible to eliminate all the flue dust by means of scrubbers, and this dust, consisting of iron oxide, may act as an energetic contact substance promoting the catalytic destruction of the sulphurous acid or calcium bisulphite by the selenium. This action is recognised by a sudden fall in the sulphurous acid and lime-contents of the digester liquor after the digestion has proceeded for some time. The sulphuric acid thus formed attacks the cellulose. Since the ill effects of the selenium are promoted both by a high temperature and long duration of digestion, the above defects are most noticeable in the manufacture of "high-boiled" bleaching pulp.—J. F. B.

Papers ; Durability of high-grade ——. W. Herzberg. Papierfab., 1914, 12, 478—479.

HJELMSÄTER (Papierfab., 1912, 10, 686, 1459) exposed a number of papers, both animal-sized and rosin-sized, to full sunlight from June to August, and then tested the deterioration produced. In all the papers, including even the tub-sized hand-made papers, the exposure to light and air produced a profound deterioration in the resistance to folding ; in many cases this had fallen to 5 per cent. of the original value. The sizing-resistance to ink had disappeared in all cases. The papers belonging to Normal class 1, both the animal-sized papers and those doubly sized (both animal and rosin sizes) showed only a slight darkening in colour ; the rosin-sized samples were much discoloured. It was concluded that the deterioration in resistance to folding produced by exposure was in some way connected with the destruction or decomposition of the sizing. From tests in which papers were steeped in solutions of aluminium sulphate, potassium sulphate and aluminium acetate and then exposed to light, the author concluded that the deterioration was brought about by the presence of aluminium sulphate ; aluminium acetate had no ill effect. Herzberg points out that in the tests recorded, those papers containing only very small quantities of aluminium salts proved no more resistant than those samples containing comparatively large proportions, so that a directly injurious influence of aluminium sulphate cannot be inferred. The fact that the introduction of a large excess of this salt into the paper was found to be injurious does not prove that papers containing normal quantities are similarly affected.—J. F. B.

Papers produced from different kinds of deciduous and coniferous woods by the soda and sulphite processes ; Comparison of ——. C. Beadle and H. P. Stevens. Paper-Maker, 1914, 47, 397—403.

COMPARATIVE tests were made with papers manufactured from bleached and unbleached pulps prepared from seven deciduous woods by the soda process and from fifteen coniferous woods by both the soda and the sulphite processes. The average results for the papers from the different classes of pulp are shown in the following table :—

Pulps.	Length of fibre in mm.	Thickness of paper in mm.	Substance in grms. per sq. m.	Breaking strain in lb. per inch width.	Breaking length in metres.	Total elongation at break.	Permanent elongation at break.	Bursting strain, corrected to uniform substance of 100 grms. per sq. m., in lb. per sq. in.
Broad-leaf, soda :								
Unbleached	1·27	0·17	103	4·5	727	2·5	1·9	9·6
Bleached	1·17	0·14	87	5·6	1178	2·9	2·0	12·8
Coniferous, soda :								
Unbleached	2·72	0·13	79	12·5	2785	3·4	2·1	32·2
Bleached	2·37	0·12	78	13·2	3026	3·5	1·7	27·4
Coniferous, sulphite :								
Unbleached	2·55	0·12	82	8·3	1928	2·9	1·9	22·9
Bleached	2·44	0·12	85	10·8	2384	3·0	1·8	23·0

(See also this J., 1913, 1103.)—A. S.

Patents.

Silk ; Treatment of waste —— or other fibres to increase their coefficient of friction on each other. W. E. Muntz, London. Eng. Pat. 8278, April 8, 1913.

Waste silk or other fibres which cannot be spun owing to lack of cohesion and shortness of staple, are treated with a solution capable on evaporation of leaving a deposit which will increase the coefficient of friction of the fibres on each other. A solution of rubber in pure carbon bisulphide may be used for this purpose, the material being treated in bulk before spinning, or the yarn itself treated after first spinning loosely.—J. B.

[Drying] Textile materials with elastic fluids ; Apparatus for treating ——. Pulsometer Engineering Co., Ltd., Reading, and T. G. Marlow, London. Eng. Pat. 8794, April 14, 1913.

An apparatus for drying rags or the like consisting of a revolving cylinder fitted inside with lifting plates which overlap and are of a yielding or springy nature. The cylinder is mounted on a set of supporting rollers near the centre and is capable of expansion in opposite directions. —J. B.

Fur ; Preparing —— for felting. E. Tweedy, Assignor to E. R. Tweedy and Matteawan Manufacturing Co., New York. U.S. Pat. 1,085,391, Jan. 27, 1914.

Fur, either on the skin or cut, is treated, preferably in a closed chamber, with ozone in order to render it capable of felting, this process replacing the usual "carroting" with mercury nitrate solution.—J. B.

Grease [from textiles] ; Process and apparatus for the continuous extraction of ——. H. Gohy. Fr. Pat. 465,097, Aug. 30, 1913. Under Int. Conv., Aug. 31, 1912.

The material (particularly textile fabric) is made to pass continuously through an apparatus with two communicating compartments. In the first the fat is extracted by a current of hot solvent circulating in the opposite direction, whilst in the second the material, after passing between rollers, is freed from solvent by a current of hot air or gas, the expelled solvent being led to a condenser. —C. A. M.

Paper ; A process for drying ——. E. P. Butts, Springfield, Mass. U.S. Pat. 1,094,195, April 21, 1914.

The air used in drying paper is first saturated with water at a definite temperature and then heated to a definite higher temperature after which it is brought into contact with the paper.—J. B.

Cellulose formates and process of making same. O. Bonhoeffer, Elberfeld, and H. Guntrum, Vohwinkel, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,093,247, April 14, 1914.

See Fr. Pat. 422,542 of 1910 ; this J., 1911, 532.—T. F. B.

Artificial horsehair ; Process of manufacturing ——. C. M. Sanlaville, Le Coteau, France. U.S. Pat. 1,093,295, April 14, 1914.

See Fr. Pat. 435,989 of 1911 ; this J., 1912, 381.—T. F. B.

Producing fermentable sugars [from sawdust]. Eng. Pat. 14,938. *See* XVII.

VI.—BLEACHING ; DYEING ; PRINTING ; FINISHING.

Aniline Black ; Thermal relationships in the formation of —— on the fibre. F. Erban. Oesterr. Chem.-Zeit., 1914, **17**, 83—87.

A description of some experiments on the dyeing of Aniline Black on tightly packed material (cops and stockings). The material was padded with a chlorate-vanadium black liquor and placed in a closed vessel in a room the temperature of which can be regulated. Observation of the temperature inside the material showed first a gradual and then a rapid rise until a maximum was reached, followed by a gradual falling off during some days. This spontaneous oxidation was dependent on the amount of vanadium present and was also influenced by the degree of dampness and the compression of the material. The rise in temperature was not harmful but on the contrary was necessary for the formation of a useful black. The conditions to be observed were a gradual approach to the critical temperature at which reaction sets in, by careful regulation of the heating of the oxidation chamber, and then, when spontaneous oxidation set in, an avoidance of drying by evaporation of the outer portions of the mass, whereby unevenness and tendering would be caused, also streakiness on the edges owing to moisture condensing on the walls of the vessel, causing local washing out of the base. When the material was loosely packed the temperature rose more quickly and the reaction was accelerated, but, owing to more rapid cooling, a lower maximum temperature was reached.—J. B.

Para-diamines ; The affinity of —— for fibres. I. Franêk. Rev. Gén. Mat. Col., 1914, **18**, 129—133.

When wool, oiled cotton or cotton mordanted wit antimony tannate is treated with a boiling solution o benzidine hydrochloride, the diamine is fixed on th fibre but unmordanted cotton and cotton mordante with aluminium oleate remain unaffected. The bas thus fixed, on diazotising and developing with β-naphtho gives a strong colouration, red-brown on the mordante cotton and red on the wool. The colour is quite differen from that obtained by combining tetrazotised benzidin with 2 mols. of β-naphthol, which is a deep brow It is concluded that one amino group only of th benzidine is diazotised and a mono-azo dyestu produced, the other amino group being attache to the fibre or to the mordant. Other shades can produced on wool by the use of various developers, *e.g.*, 2-amino-8-naphthol-7-sulphonic acid gives a brownish yellow shade of red, aminonaphthol ether a blue, *m*-toluylenediamine a fine red-brown and aminodiphenylamine an olive. Mono-amines (*e.g.*, aniline, amino-acetanilide) can be fixed on wool but cannot be diazotised on the fibre; *m*- and *p*-diamines behave similarly to benzidine on wool. An aminoazo compound (*e.g.*, Aniline Yellow) behaves like a simple mono-amine and cannot be diazotised on wool, while diamino-dibenzeneazodiphenyl develops like other diamines. In the author's opinion a diamine is fixed on wool in a manner analogous to the dyeing of basic dyestuffs, *i.e.*, viewing wool as an amino acid, the acid part of the radical combines with one of the amino groups of the diamine. This explains why one amino group only of the diamine is diazotisable.—J. B.

PATENTS.

Dyeing and drying wool, hair, rags, cotton and other fibres; Apparatus for washing, sterilising, and drying wool, hair, or rags, or for ——. W. Crowther, Bradford. Eng. Pat. 7648, April 1, 1913.

AGITATION of the material is caused by means of compressed air, forced in below the perforated false bottom of an ordinary dye-tub. An upright pipe reaching below the false bottom and delivering above the surface of the material causes an additional circulation of the liquor. Hot or cold air is used as required. After running off the liquor the material is dried and sterilised by compressed air at 230° F. (110° C.).—J. B.

Dye-vats; Method of supplying dye-compounds to ——. T. Southwell, Halifax. Eng. Pat. 7711, April 2, 1913.

THE colour, etc., is admitted to the steam pipe from which it is ejected by the steam into the dye-vat in a uniform manner. (Reference is directed to Eng. Pat. 11,402 of 1899; this J., 1899, 913.)—J. B.

Dyeing machine. W. J. Mellersh-Jackson, London. From F. J. Muir, Winchester, Mass., U.S.A. Eng. Pat. 8971, April 16, 1913.

A PRESSURE dyeing apparatus in which a basket having perforated bottom, periphery and central pipe rests on the conical bottom of the closed outer casing in such a way as to leave separate spaces between the bottom and periphery respectively of the basket and the outer casing. The circulating pump is connected independently with the bottom chamber, the peripheral chamber and the central pipe so that the circulation can be directed at will into that part of the basket where it is most required. The perforations are of gradually decreasing size towards the top of the apparatus, the central and peripheral portions of the cover of the basket are non-perforated and detachable perforated horizontal pipes are fitted between the central pipe and the peripheral wall of the basket, in order to promote uniform dyeing.—J. B.

Dyeing and otherwise treating textiles; Rotary apparatus for ——. R. P. Smith and G. E. Drum, Philadelphia, Pa., U.S.A. Eng. Pat. 9576, April 23, 1913.

THE material is carried in a rotary drum having non-perforated ends and radial partitions and perforated inner and outer walls. The drum is mounted to revolve within the dye vat, and the dye-liquor is circulated through the material in each radial compartment first in one direction and then in the reverse direction during a single rotation of the drum, the circulation being effected by blades mounted radially on an axle which revolves inside the inner wall of the drum and in a direction opposite to that of the drum.—J. B.

Aniline Black; Process and apparatus for continuous chroming in dyeing ——. J. P. Bemberg, Akt. Ges., Barmen-Ritterhausen, Germany. Eng. Pat. 21,930, Sept. 29, 1913. Under Int. Conv., Oct. 30, 1912.

INSTEAD of the usual chroming on the jigger, the cloth, after padding and oxidation, is successively saturated with a chroming liquor, squeezed, and passed through an air way, this sequence of operations being repeated as often as is necessary. The apparatus consists of a succession of chroming troughs arranged in steps, fresh liquor being supplied to the first trough according to the rate at which it is removed from the last one. After the material has passed through the first trough, it is squeezed, passed through the ager, and then into the second trough, and so on.—J. B.

Pictures; Process of transferring —— *to bases of linen, wood, and the like.* A. Christiansen, Lübeck, Germany. Eng. Pat. 29,026, Dec. 16, 1913.

PICTURES are transferred to a new base by first applying a mixture of collodion (47), celluloid varnish (47) and oil of juniper (6 per cent.), which stiffens the film of colouring matter, then immersing in a solution (*e.g.* soda) which softens its existing base, transferring the colour film to a temporary carrier, removing the original backing and finally securing the picture to the new base by an adhesive. —J. B.

Printing on fabrics; Process for ——. K. Gross. Ger. Pats. 272,526 and 272,527, Feb. 28 and Sept. 3, 1913.

(1) THE goods are treated with an alkali and a reducing agent and then printed with a "reduction dyestuff" in the form of a lithographic ink or printing ink, or they are first printed and then treated with an alkali and a reducing agent; in either case the colour is fixed by steaming. The resulting prints are fast to washing and rubbing. (2) The goods are treated with alkali and then printed with a lithographic or printing ink containing the dyestuff or its leuco-compound and a reducing agent, and finally steamed. The sparingly soluble, stable hydrosulphite compounds may be used as the reducing agent.—T. F. B.

Coloured reserve-effects under vat dyestuffs; Process for producing ——. Badische Anilin und Soda Fabrik. Ger. Pat. 272,685, May 8, 1913.

VAT dyestuffs can be divided into two groups according to their behaviour in presence of a mixture of dextrose and an easily reducible organic substance (nitro compounds or anthraquinone derivatives); one group is fixed on the fibre under these conditions whilst the other group is reserved. This process for producing coloured reserve effects consists in applying to the fibre one dyestuff from each of the above groups in presence of a mixture of dextrose and a reducible organic compound.—T. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Iodides; Direct iodometric determination of soluble ——. W. Stüwe. Apoth.-Zeit., 1914, 29, 382.

THE iodide is decomposed by adding an excess of potassium iodate and acidifying with dilute nitric acid. The free acid is then neutralised by barium carbonate, the previous addition of a small quantity of alcohol being recommended to prevent foaming and consequent loss of iodine. To the neutral solution potassium iodide is added to bring the precipitated iodine into solution, the excess of barium carbonate is allowed to settle, and the iodine determined by titration of an aliquot portion of the clear solution with standard thiosulphate. Five-sixths of the iodine indicated represents that present originally as iodide. The method is applicable in the presence of chlorides, but not of bromides.—G. F. M

Pyrites and sulphuric acid in the United States; Production of —— *in* 1913. W. C. Phalen. Oil, Paint, and Drug Rep., April 27, 1914. [T.R.]

THE production of pyrites in the United States in 1913 was 341,338 long tons, valued at $1,286,084. In 1912, the output amounted to 350,928 tons, valued at $1,334,259. The output of by-product pyrites, obtained in connection with coal mining, fell off materially. The imports of pyrites during 1913 were 850,592 tons, and in 1912 970,785 tons.

According to returns for the year 1913 the production of sulphuric acid in the United States was 3,538,980 short tons of 50° acid, valued at $22,366,482. This does not include a small amount of fuming acid but includes by-product acid obtained in the smelter industry. The acid produced at copper and zinc smelters in 1913 amounted to 790,296 short tons of 50° acid, valued at $4,346,272. The production of acid by grades is tabulated in detail below :—

Grade.	Quantity. tons.	Value.
50° B.	1,643,318	$9,212,917
60° B.	509,929	3,202,528
66° B.	797,104	9,282,422
Other grades	63,158	986,659
Total	3,013,509	$22,684,526
Total reduced to 50° B. acid.*	3,538,980	$22,366,482

*Exclusive of a small amount of fuming acid.

Rare earths ; Some errors in the determination of the —— as hydroxides. T. O. Smith and C. James. Chem. News, 1914, **109**, 219—220.

The determination of the rare earths by precipitation with ammonia or sodium hydroxide, and weighing as oxide, gave higher results than those obtained by precipitating as oxalate. The amount of hydroxide added in excess also influenced the result, and the higher values given by this method are ascribed to the carrying down of sodium by the precipitate and to the formation of basic salts. By the oxalate method perfectly concordant results were obtained.—G. F. M.

Sulphur in spent oxide ; Determination of —— by combustion. C. W. Somerville. J. Gas Lighting, 1914, **126**, 241—242.

The sulphur is burnt in a stream of oxygen, the sulphur dioxide absorbed in alkali, and the alkaline sulphite solution oxidised with hydrogen peroxide, the sulphate being then determined either by titrating the excess of alkali with acid, or as barium sulphate. A simple apparatus is described. The combustion vessel is a vertical glass cylinder, in which is placed a crucible containing the spent oxide. The oxygen is led through a vertical tube to the interior of the crucible, in which the oxide is ignited. The determination can be completed in 20 to 25 minutes, the results agree within 0·5 per cent. and show a yield of sulphur 0·3 to 1 per cent. higher than by extraction with carbon bisulphide.—A. T. L.

China clay : Adsorptive power of ——. P. Rohland. Kolloid-Zeits., 1914, **14**, 193—195.

According to Carli (Z. physik. Chem., 1913, **85**, 2). colloidal ferric hydroxide is not appreciably adsorbed by kaolin. The author points out that some kaolins become plastic and acquire adsorptive power only after prolonged contact with water, whereby colloids, principally hydroxides of aluminium and silicon, are formed. A kaolin from Hohburg, Saxony, adsorbed colloidal ferric hydroxide almost completely. This kaolin consisted of : clay substance 96, felspar 1, and quartz 3 per cent., and yielded the following results on analysis ; loss on ignition, 12·67 ; SiO_2, 49·96 ; Al_2O_3, 36·33 ; Fe_2O_3, 0·72 ; CaO, traces ; K_2O, Na_2O, 0·34 per cent.—A. S.

Reactions in reversed flames. II. Reduction of liquid anhydrous chlorides of groups 3—5 of the periodic system in the reversed chlorine-hydrogen flame. F. Meyer and H. Kerstein. Ber., 1914, **47**, 1036—1049.

Experiments of a similar character to those described previously (this J., 1912, 1030) with an improved apparatus have been made. The previous results were confirmed and the yield of titanium trichloride from the tetrachloride was increased to 70 per cent. by using a very rapid current of hydrogen. Boron chloride and silicon tetrachloride were not reduced. Carbon tetrachloride gave a deposit of finely divided, very voluminous carbon (C 94·6 per cent.) containing small proportions of chlorine and hydrogen which could not be removed by heating in a vacuum at 600° C. ; the carbon readily yielded mellitic acid when oxidised with fuming nitric acid. Phosphorus pentachloride gave a red product (P 92—94 per cent.) very similar to Schenck's scarlet phosphorus. Antimony pentachloride gave a greyish black powder consisting of about 93 per cent. of black antimony and 7 per cent. of the trichloride. Vanadium tetrachloride gave a very voluminous violet powder consisting of VCl_2 about 80 and VCl_3 20 per cent.—A. S.

Carbides of uranium and thorium ; Composition of the gaseous mixtures produced by the action of water on ——. P. Lebeau and A. Damiens. Bull. Soc. Chim., 1914, **15**, 367—370.

The experimental results are shown in the following table :—

	Uranium carbide.			Thorium carbide.	
	(1)	(1)	(2)		
Duration of reaction, days	6½	15	23	3	3½
Volume of gas per grm. of carbide, c.c.	35·65	34·97	32·09	55·30	56·20
Composition of gas, per cent :					
Hydrogen	49·70	49·53	28·91	59·77	59·46
Methane	14·15	11·81	19·79	3·09	3·16
Ethane	23·43	24·89	22·68	10·66	10·72
Propane	2·97	2·51	5·55	1·66	1·36
Butane	0·90	0·62	4·73	0·83	0·86
Ethylene	2·18	2·34	1·36	2·71	2·85
Propylene and homologues	5·34	5·79	14·43	6·72	6·37
Acetylene hydrocarbons	1·33	2·51	2·55	15·16	15·22

Sample (1) of uranium carbide contained 1·47 per cent. of graphite ; sample (2) contained U 91·6 per cent. and was free from graphite. The thorium carbide contained Th 88·11 per cent., combined carbon 9·21, and graphite 3·09 per cent.—A. S.

Nitrogen ; The "active" modification of ——. H. B. Baker and R. J. Strutt. Ber., 1914, **47**, 801—804. (See also this J., 1914, 311.)

A reply to Tiede and Domcke's assertion (this J., 1914, 76) that the after-glow characteristic of "active" nitrogen depends upon the presence of traces of oxygen and that it is not given by nitrogen prepared from potassium azide. Experiments are described showing that nitrogen which had been stringently purified from oxygen still exhibited the phenomenon, as did also nitrogen prepared from potassium azide.—J. R.

Nitrogen ; The active modification of ——. II. H. B. Baker and R. J. Strutt. Ber., 1914, **47**, 1049—1055. (See also preceding abstract.)

Contrary to the statement of Tiede and Domcke (this J., 1914, 254), commercial nitrogen from a cylinder still gives the after-glow characteristic of active nitrogen even after it has been purified by copper heated to 400° C. The existence of active nitrogen has been proved conclusively by its action on various metals with formation of nitrides and on organic compounds with formation of hydrogen cyanide.—A. S.

Tellurium and selenium ; Action of sodium hydrosulphite upon ——. L. Tschugaeff and W. Chlopin. Ber., 1914, **47**, 1269—1275.

Sodium telluride is conveniently obtained by heating at 70°—80° C., sodium hydrosulphite (or better, because more stable, rongalite, a double compound of formaldehyde and sodium sulphoxylate, $CH_2(OH).OSONa$ with finely divided tellurium in alkaline solution, either in closed tubes or in an atmosphere of hydrogen, until the violet colour first formed has disappeared. On cooling sodium telluride crystallises out. The mechanism of the reaction is probably as follows:—

$$OS(ONa)Na \xrightarrow{Te} OS(ONa)TeNa \xrightarrow{2NaOH} Na_2Te + Na_2SO_3 + H_2O.$$

The Na_2Te then dissolves tellurium to form violet polytellurides, which are again reduced by the hydrosulphite: $Na_2Te_2 + Na_2S_2O_4 + 4NaOH = 2Na_2SO_3 + 2Na_2Te + 2H_2O$. From sodium telluride benzyl telluride was prepared, and he above reactions were extended with similar results to elenium.—G. F. M.

Boron; Hydrides of ——. IV. Hypoborates resulting from the interaction of gaseous hydrides of boron and bases. A. Stock and E. Kuss. Ber., 1914, **47**, 810—826.

HE hydrides, B_4H_{10} and B_2H_6, are absorbed by very conentrated aqueous potassium hydroxide, and crystalline otassium hypoborate separates from the well-cooled olutions:

$$B_4H_{10}+4KOH=4KOBH_3+H_2.$$
$$B_2H_6+2KOH=2KOBH_3+H_2.$$

n dilute alkaline solution the hypoborate changes gradually nto metaborate and hydrogen is evolved. A similar change curs immediately upon acidifying:

$$KOBH_3+H_2O=KBO_2+5H.$$
$$KOBH_3+HCl+2H_2O=H_3BO_3+KCl+5H.$$

otassium hypoborate is stable in dry air. The freshly-eparad aqueous solution, which is alkaline in reaction, ssesses very marked reducing properties. Solutions of e salts of barium, magnesium, zinc, etc. yield precipitates a mixture of borate and hydroxide, while solutions of lts of silver, mercury, arsenic, etc. are reduced to the free ment. Copper sulphate solution yields a precipitate of pper hydride, and solutions of nickel salts give a highly aracteristic black deposit of nickel boride, Ni_2B. The ucture of the corresponding acid is given as $HO.B \vdots H_3$. —J. R.

d phosphorus; Formation of ——, by oxidation of phosphorus vapour. V. Kohlschütter and A. Frumkin. Ber., 1914, **47**, 1088—1100. (See also this J., 1914, 255.)

HEN oxygen is brought into contact with phosphorus pour at low pressures a dark-red, homogeneous, transent deposit is produced, which readily breaks down o red phosphorus and a compound containing the remain- phosphorus and all the oxygen present in the original sit.—J. R.

orimetric method for detecting and determining nitrates and nitrites. Letts and Rea. *See* XXIII.

Patents.

ali; Electrolytic production of —— using a mercury thode. L. T. S. Madsen. Ger. Pat. 272,476, July 8, 13.

A OLUTION of salts of several alkali metals is used as trolyte, whereby an amalgam richer in alkali metal be obtained. The process is specially applicable e mixture of potassium and sodium chlorides produced tassfurt.—A. S.

gen; Process for fixing —— by means of ferro-aluminium. Soc. Générale des Nitrures, Paris. Eng. Pat. ,030, Nov. 24, 1913. Under Int. Conv., June 7, 1913.

RO-ALUMINIUM, which may contain other elements or., titanium, etc.), is treated with nitrogen or gases ining it at a high temperature. The product contains inium nitride, and ammonia or ammonia and alumina be obtained from it by known methods.—F. Sodn.

Nitride of iron; Manufacture of —— and, in general, of metallic nitrides, especially for use as fertilisers, or as a source of production of ammonia. J. Margoles. Fr. Pat. 465,265, Nov. 24, 1913.

An oxide or other compound of a metal (especially iron) is submitted, at a high temperature (500°—1200° C.), to the action of atmospheric nitrogen, in the presence of hydrogen (prepared, for example, by electrolysis) or a gaseous mixture containing hydrogen. The nitride obtained may be treated with steam, to regenerate the metallic oxide and produce ammonia. By adding carbon, cyanides, cyanamides, or (when using sulphides) thiocyanates can be obtained. —F. Sodn.

Nitrogen compounds [from carbides]; Process and apparatus for the preparation of ——. C. Krauss, P. Stähelin, and Akt.-Ges. für Stickstoffdünger. Fr. Pat. 464,750, Nov. 11, 1913.

Carbide is transported by mechanical means through a horizontal tubular furnace, divided into preheating, heating, reaction, and cooling sections, whilst a current of nitrogen is passed in the opposite direction. Or, superposed layers of carbide are exposed in a furnace comprising a series of intercommunicating chambers, each of which constitutes in turn a heating, reaction, and cooling unit, the circulation of gas being so arranged that cold nitrogen can be admitted directly into each chamber, and any excess of gas passed from one chamber to the next. In both forms of furnace the temperature is controlled, partly by external means and partly by the admission of cold nitrogen.—F. Sodn.

Oxides of nitrogen; Production of —— by oxidation of ammonia in presence of catalysts. Badische Anilin und Soda Fabrik. Fr. Pat. 464,237, Oct. 29, 1913. Under Int. Conv., Jan. 30, 1913.

The reacting gases are filtered or otherwise treated to remove suspended particles immediately before entering the contact chamber, or, after being rendered free from dust, they pass on their way to the catalyst, only through apparatus made of nickel or other metal yielding no particles to them.—F. Sodn.

Nitrogen and oxygen [by surface combustion]; Preparation of compounds of ——. C. Krauss and P. Staebelin. Fr. Pat. 465,045, Nov. 18, 1913. Under Int. Conv., July 26, 1913.

Liquid or gaseous fuel, mixed with nitrogen and oxygen, is made to undergo surface combustion in a chamber filled with porous or granular refractory material, through which it is forced, the products being suddenly cooled (partly by expansion) and treated for the production of nitric acid by known methods. The refractory material may be mixed or coated with substances (such as rare earth oxides) which promote the reaction.—F. Sodn.

Silica, alumina, and bases; Method of manufacturing base-exchanging substances containing ——. Permutit Aktienges., Berlin. Eng. Pat. 1039, Jan. 14, 1914. Under Int. Conv., April 30, 1913.

Melts obtained in the manufacture of base-exchanging substances containing silica, alumina, and other bases are lixiviated with a solution containing active, amorphous silica, soluble colloidal silica, water-glass, or any substance containing silica capable of combination, or with a solution containing substances capable of precipitating silica, such as acids (of sufficiently low concentration to prevent excessive decomposition) or acid salts of alkali metals (*e.g.*, bisulphites or bisulphates).—F. Sodn.

Chlorates; Process of making [electrolytically] —— and apparatus therefor. G. Kolsky, Niagara Falls, N.Y. U.S. Pat. 1,092,369, April 7, 1914.

In a non-diaphragm cell for the electrolytic production of chlorates, a series of electrodes (preferably inclined) is disposed to provide an open or grid-like structure, through which the electrolyte may repeatedly circulate under the influence of the liberated hydrogen. Sufficient evolution of gas is maintained to induce active circulation and effect depolarisation, the lines of flow of the electrolyte passing electrodes of opposite polarity in rapid succession. —F. Sodn.

Compounds of chromic oxide; Manufacture of ——, starting with chromic acid or chromates. Chemische Fabriken vorm. Weiler-Ter Meer. Fr. Pat. 464,909, Nov. 13, 1913. Under Int. Conv., July 7, 1913.

Chromic acid or a chromate is reduced by means of glucose or other sugar in neutral or alkaline solution, with addition, if necessary, of sodium thiosulphate. For example, a mixture of 92 kilos. of sodium chromate, in 78 litres of water, 40 litres of glucose solution, and 22 kilos. of sodium thiosulphate is heated to 70°—80° C. The products are suitable for the preparation of normal or basic salts for use in mordanting and tanning.—F. Sodn.

Oxides and hydroxides of heavy metals; Process for obtaining —— practically free from basic salts. F. Cochlovius. Ger. Pat. 272,182, Feb. 2, 1913.

Solutions of salts of heavy metals, or wet precipitates of oxides or hydroxides, admixed with basic salts, are heated with a basic substance, such as quicklime, under pressure in an autoclave.—A. S.

Hydrogen; Process of generating ——. C. Ellis, Montclair, N.J. U.S. Pat. 1,092,903, April 14, 1914.

A bed of fuel (*e.g.*, coke, with a small proportion of fluxing material), rendered white hot by a blast of air, is treated with heavy petroleum oil, which may also be applied to the refractory surface of the containing chamber. The gases produced during the period of "blowing" and the hydrogen formed in the gas-making stage are removed by means of steam, passed over but not through the bed of fuel.—F. Sodn.

Graphite; Chemical process of purification of natural ——. E. N. Lainé. Fr. Pat. 464,642, Jan. 17, 1913.

Crude graphite is treated with dilute acid (*e.g.*, hydrochloric acid) to extract carbonates and oxides, the washed and dried residue fused at a high temperature with sodium carbonate, sodium and potassium carbonates, or sodium hydroxide, and the product repeatedly washed with water (preferably at 80° C.), then with acidulated water, and finally with water again. The proportion of ash may be reduced from 40 to less than 1·5 per cent.—F. Sodn.

Oxides of nitrogen; Process of producing ——. H. Wolf. Assignor to Badische Anilin und Soda Fabrik. Ludwigshafen on Rhine, Germany. U.S. Pat. 1,094,182, April 21, 1914.

See Fr. Pat. 464,237 of 1913; preceding.—T. F. B.

Ammonia; Production of ——. C. Bosch, A. Mittasch, and H. Wolf, Ludwigshafen, and G. Stern, Mannheim, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat 1,094,194, April 21, 1914.

See Fr. Pat. 425,099 of 1910; this J., 1911, 1012.—T. F. B.

Nitrides such as that of aluminium; Process for the manufacture of ——. Soc. Générale des Nitrures, Paris. Eng. Pat. 21,366, Sept. 22, 1913. Under Int. Conv., Dec. 16, 1912. Addition to Eng. Pat. 11,091 of 1913, dated May 13, 1912.

See Fr. Pat. 457,723 of 1913; this J., 1913, 1010.—T.F.B.

Aluminium nitride; Process for the manufacture of ——. O. Serpek, Assignor to Soc. Générale des Nitrures, Paris. U.S. Pat. 1,094,171, April 21, 1914.

See Eng. Pat. 8348 of 1912; this J., 1913, 875.—T. F. B.

Radio-active substances or vessels enabling large quantities of radio-active liquids to be obtained economically; Process for producing ——. H. Farjas, Paris. Eng. Pat. 14,530, June 23, 1913. Under Int. Conv., July 1, 1912.

See Fr. Pat. 456,990 of 1912; this J., 1913, 1028.—T. F. B.

Catalytic material [nickel suboxide] and process of producing the same. T. Boberg. Assignor to Techno-Chemical Laboratories, Ltd., London. U.S. Pat. 1,093,377, April 14, 1914.

See Eng. Pat. 4702 of 1912; this J., 1913, 705.—T. F. B.

Catalysts and the manufacture of hydrogen. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 8864, April 15, 1913. Addition to Eng. Pat. 27,955, Dec. 4, 1912.

See Fr. Pat. 459,918 of 1913; this J., 1914, 24.—T. F. B.

VIII.—GLASS; CERAMICS.

Porcelain; Observations on the burning of ——. R. Reindel. Sprechsaal, 1914, **47**, 285—287.

The behaviour of an experimental oven was studied by means of Seger cones, a pyrometer, a manometer, and analyses of the oven gases. The readings of the pyrometer showed higher temperatures than those indicated by cones, the difference amounting sometimes to 100° C at the beginning of the burn and diminishing at late stages. Temperature curves were not regular in thei ascent, but dropped at each addition of fuel. The draugh also varied from 25—50 mm. according to the conditio of the fire. Analyses of the fire-gases were conducte at cone 09a, the point at which they begin to influenc the character of porcelain. A content of 3—5 per cen CO is necessary at this temperature, but at cones 8 or 1 per cent. is sufficient to maintain the reducing characte of the oven atmosphere in regard to porcelain.—H. H. S.

Patents.

Oven with concentric chambers for the ceramic industr A. Charlier, Morialmé, Belgium. Eng. Pat. 10,39 May 2, 1913.

See Fr. Pat. 457,398 of 1913; this J., 1913, 1012.—T. F.

Production of gas-tight seals, or closures, between metal a vitreous material. Eng. Pat. 23,854. *See* XXIII.

IX.—BUILDING MATERIALS.

Patents.

Concrete; Waterproof —— and process of making same. R. K. Meade. Roland Park, Md. U.S. P 1,092,933, April 14, 1914.

Cementitious matter is mixed with "a powdered fill the particles of which have been previously coated wit thin film of mineral oil.—W. E. F. P.

Cement kilns, for transforming grey into white Portl cement; Rotary ——. M. Maguet. Fr. Pat. 464, Jan. 11, 1913.

A chamber supplied with reducing gas (from a produ is interposed between the rotary kiln and the co chamber. Ferric compounds are reduced in the redu atmosphere and re-oxidation is prevented by rapid co in an inert atmosphere (preferably by means of w or steam).—F. Sodn.

Cement mixtures; Method of lowering the sintering temperature of ——. Bruck, Kretschel und Co. Ger. Pat. 272,171, March 16, 1913.

The fine material separated in the purification of blast-furnace gas is added to the mixture of cement raw materials. —A. S.

Gypsum; Gas kiln for the burning of ——. C. M Stein et Cie. Fr. Pat. 464,613, Jan. 17, 1913.

A combustion chamber is provided at one end with a row of burners, at the other with an opening for charging and discharging. The burners are connected with controlled supplies of air and gas from a producer, and the supply of the latter is cut off before the gypsum is introduced into the heated kiln.—F. Sodn.

Wood or analogous fibrous material; Impregnation and colouration of ——. L. S. Bache. Fr. Pat. 464,791, Oct. 27, 1913.

The dried material is treated with a boiling mixture of a aturated hydrocarbon, wax, resin, stearic acid, and a olouring matter soluble in the mixture (preferably, equal weights of carnauba wax and resin, with an excess of araffin of m.pt. 40°—60° C.), until, by increase of density, t tends to sink in the bath. Impregnation is uniform, nless there be imperfection of structure, due to dry rot, tc., which is thus rendered apparent. The product nay be applied in the manufacture of antifriction bearings "*coussinets et surfaces portantes*"] which are permanently elf-lubricating.—F. Sodn.

ood; Process for preserving and fireproofing —— by impregnating with solutions of ammonium and magnesium salts and an antiseptic. Grubenholzimprägnierung Ges. m. b. H. Ger. Pat. 271,797, Nov. 16, 1912. Addition to Ger. Pat. 247,694.

he salts of nitrohydroxy-hydrocarbon-sulphonic acids re used as preservatives. Thus, the impregnating olution may contain 200 kilos. of magnesium sulphate nd 100 kilos. of ammonium sulphate in 1000 litres of ater, together with 20 kilos. of zinc nitrophenolsulphonte, or 20 kilos. of magnesium dinitrocresolsulphonate, or 0 kilos. of a mixture of mono- and disulphonates, obtained y sulphonating and then nitrating carbolic acid and eutralising with zinc oxide, magnesium oxide or carbonate, lcium hydroxide, or copper oxide.—T. F. B.

arble; Manufacture of artificial —— [from leather]. O. E. Heuschkel, London. U.S. Pat. 1,094,366, April 21, 1914.

ee Eng. Pat. 12,845 of 1910; this J., 1911, 1061.—T. F. B.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

teel.] The Tolbot process in comparison with other open-hearth refining processes. F. Schuster. Iron and Steel Inst., May, 1914. [Advance proof.]

r Witkowitz (Silesia), the duplex process of steel manucture was abandoned for the cheaper basic open-hearth ethod. In experimental runs made in Talbot, Wellman lting) and fixed open-hearth furnaces, the first-named s found to be superior to the other types; some data e tabulated below. The quality of steel produced was dependent of the type of furnace employed :—

	Talbot.	Wellman.	Open-hearth.
scrap added to charge, per cent.	5	10—15	20
tio of cost of construction	1·659	1·259	1
tio of working costs	0·882	1·07	1
tio of total cost of production	1	1·05	1·07
as of steel produced with one lining	49,200	27,600	27,800

—W. R. S

Steel; Production of —— direct from ore. E. Humbert and A. Hethey. Iron and Steel Inst., May, 1914. [Advance proof.]

Tests were made with Swedish and Brazilian iron ores in a Héroult electric furnace of 6 tons capacity, using coke as fuel. It is concluded that the economic manufacture of steel direct from ore is practicable; that the product, by reason of its comparative freedom from hydrogen, nitrogen and other impurities, is superior, especially in toughness, to steel obtained by present methods; that the electric furnace employed should be of a type permitting violent ebullition of the bath without overflowing; that either charcoal, coke or anthracite may be used as fuel; and that anthracite electrodes will probably be most economical.—W. E. F. P.

Steel ingots; The forms in which sulphides may exist in ——. J. O. Arnold and G. R. Bolsover. Iron and Steel Inst., May, 1914. [Advance proof.]

Mild steels with varying percentages of sulphur and manganese were prepared from pure Swedish bar iron, American washed iron, ferrous sulphide specially prepared from Swedish bar and flour sulphur, and "thermit" metallic manganese. Microphotographs of typical sections were prepared. The first type (Mn below 0·1, S about 0·6) showed only pale-brown meshes of iron sulphide; the second (Mn 0·41—1·11, S 0·20—0·58) sharply segregated and sometimes juxtaposed areas of both pale-brown iron sulphide and dove-grey manganese sulphide in variable proportions determined by the ratio of sulphur and manganese; and the third (Mn 1·11, S 0·28) only dove-grey manganese sulphide. In a sample containing Mn 0·75 and S 0·45 (type 2), the manganese sulphide appeared largely in small ovoids arranged in a fan-like pattern. It is considered that these groups of manganese sulphide particles form strong evidence of the presence of a eutectic of ferrite and manganese sulphide existing in the fluid steel. This eutectic separates on (or possibly before) solidification of the steel in rounded masses which eventually decompose into their eutectic components. The specimens in which the eutectic was observed all contained aluminium.—T. St.

Sulphur in pig iron and steels; Colorimetric determination of ——. G. Misson. Iron and Steel Inst., May, 1914. [Advance proof.]

One grm. of the sample is treated with 50 c.c. of hydrochloric acid (sp. gr. 1·14) and 10 c.c. of benzine (sp. gr 0·71) in a slightly tapering glass vessel (80 mm. diam. and 95—100 mm. high), over the open end of which is placed a sheet of filter-paper (10 cm. square) which has been soaked in a solution containing 10 grms. of arsenic trioxide and 30 c.c. of concentrated hydrochloric acid per litre; the paper is covered by a piece of white felt held in place by a sheet of ebonite and a disc of lead. The hydrogen sulphide stains the paper uniformly yellow and the tint is compared by transmitted light with a standard treated in the same way.—A. S.

[*Iron-carbon.*] *The laws of the transition of the carbide-system into the graphite-system.* W. Guertler. Stahl u. Eisen, 1914, **34**, 520—525, 751—754.

The diagrams of the graphite-system and the cementite-system, and the conditions that determine the form that carbon in the iron-carbon system will take are discussed. The triangular diagram showing total carbon, graphite and combined carbon in the plane of the paper, is described, and the operations of annealing and casting cast-iron are discussed with reference to this diagram.—T. St.

Steel; New reagent for etching mild ——. W. Rosenhain and J. L. Haughton. Iron and Steel Inst., May, 1914. [Advance proof.]

The reagent is composed of: ferric chloride 30 grms., concentrated hydrochloric acid 100 c.c., cupric chloride 1 grm., stannic chloride 0·5 grm., water 1 litre, and it is necessary that the surface of the metal to which it is applied be perfectly clean. The reagent deposits a thin film of metallic copper. On hardened steels, especially of low and moderate carbon contents, the results were similar to those obtained with picric acid, etc., but the outlines of the copper films were very sharp, especially on martensite: troostite and sorbite were darkened. On practically pure carbon steels with the usual ferrite-pearlite structure, the effect was the reverse of that obtained with picric acid, etc., the pearlite being unaffected. The reagent proved specially useful for revealing the distribution of phosphorus in mild steels, giving results which compared favourably with those obtained by Stead's method of heat-tinting (this J., 1900, 1019). In addition to the typical etching effect, discoloured patches surrounding small black pits were frequently observed, usually grouped around a slag enclosure.—A. S.

Metals; The hardening of ——*, with special reference to iron and its alloys.* C. A. Edwards and H. C. H. Carpenter. Iron and Steel Inst., May, 1914. [Advance proof.]

The mechanism of annealing. The softening of metals by heating and subsequent slow cooling is attributed to the elimination, by recrystallisation, of the unstable, hard, amorphous material which exists as envelopes around the crystals, and not to any change in the nature or hardness of the crystals themselves. During this recrystallisation, which increases with the temperature and proceeds by the gradual growth of certain crystals at the expense of others, the amorphous envelopes act like ordinary electrolytes, the substance of one crystal being transferred to another. *Hardening by quenching.* The quenching of carbon steels results in severe stresses which cause very pronounced crystal twinning, the latter, apparently, being connected directly with the intensity of the thermal changes that occur when the mass is slowly cooled, and particularly with the carbide or Ar_1 inversion, At all the surfaces of slip upon which twinning occurs, amorphous layers are produced, the presence of which is the ultimate cause of hardening by quenching. In the so-called austenitic steels the special elements present give rise to the formation of new compounds which lower the temperature at which the carbon separates from solution and also decrease the velocity of the carbide change, so that rapid quenching is not necessary to preserve the mass in the same physico-chemical constitution as properly quenched carbon steels. In both cases the carbide change is inhibited by pressure; but when this is brought about by external means such as quenching, twinning of the crystals is produced, whereas when the whole of the necessary pressure is already inherent in the mass, as osmotic pressure, no internal crystalline disturbance occurs. The amount of twinning produced by quenching is proportional to the amount of the inversion which has to be suppressed by external means, or inversely proportional to the retarding influence of the special elements present; hence twinning is entirely absent when the necessary internal pressure is sufficient, as when the required amount of nickel is contained in the steel. *Constitution of martensite and austenite.* Although direct experimental proof is still wanting, the suggestion, previously made by one of the authors, that martensite and austenite are merely twin crystals of the same constituent, was further supported by the investigation of certain quenched copper-aluminium alloys analogous to the carbon steels in which martensite and austenite are found.—W. E. F. P.

Steel dies; A case of decarburisation during the hardening of ——. H. C. Greenwood. Iron and Steel Inst., May, 1914. [Advance proof.]

Steel containing C and Cr about 1 per cent. each, was covered with powdered charcoal and kept for 1½ hours at 820° C. After quenching, the face was very soft, and poorer in carbon. This did not occur when the charcoal was omitted, or replaced by sand.—W. R. S.

[Steel]. Case-hardening practice; Some recent improvements in ——. H. L. Heathcote. Iron and Steel Inst., May, 1914. [Advance proof.]

The temperature of the hardening pots is ascertained by means of an optical pyrometer, a series of dye solutions being used, calibrated so that the object just becomes visible at a definite temperature when observed through the coloured layer. Wood charcoal impregnated with soda ash and free from fine particles was found to be the best case-hardening composition: it can be used over and over again, and gives uniform results (0·9—1·1 per cent. C). Quadrant sclerometers for testing surfaces of various shapes are described (see Eng. Pat. 6622 of 1913; this J., 1914, 425). A suitable solution for examining surfaces that cannot easily be tested with a sclerometer is composed of: water 1000, alcohol 1000, nitric acid 100 c.c. On immersing for ½ to 1 minute, martensite gives brown or light blue, troostite dark blue or dark grey stains; ferrite and pearlite are hardly stained at all.—W. R. S.

Iron; The recrystallisation of deformed ——. C. Chappell. Iron and Steel Inst., May, 1914. [Advance proof.]

The effect of the extent of deformation and the temperature of the succeeding annealing on the nature of the resulting recrystallisation in iron and mild steel was studied. Deformation was produced by wire-drawing, by means of a hardened steel needle actuated by a Brinell press, and by rupture in a tensile testing machine. Violent deformation, such as that produced immediately below the Brinell needle, at the point of rupture of a pulled sample, and by wire-drawing, gave rise, on heating to 350°—500° C., to the disintegration of the original ferrite crystals. Above 500° C. new crystals appeared, which grew with great rapidity, until at 570° C. the disintegrated crystal "debris" was completely recrystallised into new crystals, smaller than those originally present. From 570° to 700° C. these crystals increased steadily in size, but above 700° C. little further change took place until complete recrystallisation occurred at Ac3. In samples subjected to deformation by the Brinell needle and by pulling, the zone of violent deformation merged into one characterised by an enormous increase in crystal size on annealing. This recrystallisation began at about 600°—650° C., but the maximum rapidity of growth occurred between 700° and 800° C., whilst from 800° C. up to the destruction of the coarse crystallisation, further growth took place only to a comparatively slight degree. In al cases the temperature of recrystallisation decreased as th degree of deformation increased. In pulled samples of iro almost free from carbon the lower limit of stress require to produce distinctive recrystallisation effects on annealing practically corresponded to the yield point. It is con sidered that the phenomena attending plastic strain ar capable of simpler explanation than by the theory of a amorphous cement or intercrystalline skin. In tests a 100° to 1000° C. permanent recrystallisation effects wer produced by deformation at all temperatures fro atmospheric up to Ac3 in practically carbonless iro In the case of mild steel the effect of carbon wa to restrict the size of the crystals developed, to mak a higher degree of stress necessary to produce growth, an to lower the temperature at which the coarse crystallini was destroyed. The recrystallisation phenomena of d formed iron may be used to determine the lines of flo produced in mechanical testing, etc.—T. St.

Manganese steel; Magnetic and mechanical properti of ——. R. A. Hadfield and B. Hopkinson. Iron a Steel Inst., May, 1914. [Advance proof.]

Manganese steel (Mn 12, C 1¼ per cent.) which w non-magnetic in its normal water-toughened form beca magnetic and brittle when heated to 520° C. and slow cooled. The change was rapid at first and then beca slower, and was not complete even after 600 hrs. heatir the final value at this temperature would probably about 66 per cent. of that for pure iron. At lo temperatures the change was much slower: after 23 d at 300° C. magnetism was just perceptible, and a 50 hours at 450°—500° C., the value was 7 per cent. of t for iron. Above 650° C. the change was more rapid but the maximum value attainable was much lower than at 520° C. At 700° C. only very slight magnetism could be attained. A steel fully magnetised at 520° C. lost its magnetism when heated above 640° C. and then quenched, the rate and extent of the loss becoming greater as the temperature was raised; the steel was almost entirely demagnetised after a few minutes at 750° C. Immersion in liquid air did not increase the magnetism of a non-magnetic steel or diminish that of a fully magnetised one, but it increased that of a steel in an intermediate condition. The change from the non-magnetic to the magnetic form was accompanied by an increase of volume and by an evolution of heat. There is a close connection between mechanical properties and magnetism, but heat treatment which almost entirely destroyed ductility only produced a slight amount of magnetism. In photomicrographs the development of a network of a hard constituent was observed which even in very small quantity made the metal brittle: this is probably the magnetic constituent. Analogous results from steels with less manganese and more carbon led to the conclusion that in all cases the magnetic form is probably stable below a certain temperature and the non-magnetic form above it. The transition at this temperature is very low and the effect of manganese is probably to lower this temperature slightly, and to reduce the velocity of the transition very greatly.—W. H. P.

on-nickel alloys; Resistometric studies of some ——. A. P. Schleicher and W. Guertler. Z. Elektrochem., 1914, **20**, 237—252.

IRES of three alloys containing respectively Ni 35·25, 0·6, and 25·2 per cent. were heated *in vacuo* in an electric rnace, and their electrical resistance measured at different mperatures. There was a pronounced discontinuity the temperature-resistivity curve at about 420° C. for the ·25 per cent. alloy and at 700° C. for the 30·6 per cent. oy. The 25·2 per cent. alloy in its original condition ve abnormally low values, but the resistance became gher with each successive heating until the wire became bilised and gave a regular curve with a discontinuity 900° C. The significance of these results is discussed connection with the constitution of the alloys and their gnetic properties.—W. H. P.

rome steels; The magnetic properties of a graded series of —— at ordinary and low temperatures. M. B. Moir. Phil. Mag., 1914, **27**, 830—842.

steels (containing Cr 1, 4·05, 8, 12, 16 and 20 per cent. pectively) were tested at 15° and —190° C. (liquid air) the forged and rolled condition, after annealing from ° C., and after quenching from 900° C.; after every nge of temperature, each specimen was subjected a process of reversals at the new temperature before urther magnetic test was made. The effect of lowering temperature was to diminish the susceptibility for fields and to increase it for high fields. In the case of ealed specimens, the value of the magnetising force which the curves corresponding to 15° C. and —190° C. ectively, crossed, increased with the chromium tent up to 12 per cent. and then decreased; immersion quid air produced a permanent effect not obliterated n the specimen regained a temperature of 15° C. In the of quenched specimens, the crossing of the curves urred at very high values of the magnetising force; ersion in liquid air had no permanent effect. In all s the residual magnetism and the coercive force were ter at —190° C. than at 15° C.—W. E. F. P.

; Influence of molybdenum upon the corrodibility of —. J. N. Friend and C. W. Marshall. Iron and eel Inst., May, 1914. [Advance proof.] (See also is J., 1913, 537.)

LS without and up to Mo 4·1 per cent. were subjected e action of tap water, 3 per cent. salt solution, dilute uric acid (0·05 and 0·5 per cent.), and alternate wet dry tests. Molybdenum up to 4 per cent. did not a marked influence upon the corrodibility by tap water, salt solution, and 0·05 per cent. sulphuric acid. The "corrosion factors" (relative corrosion compared with that of a carbon steel taken as standard) for the 0·5 per cent. acid was almost identical with the mean factors obtained in the preceding tests. In the wet and dry tests, carbon increased the resistance to corrosion while molybdenum decreased it. More than 1 per cent. Mo in steel appears to be undesirable.—W. R. S.

Blast-furnace gas purification; Development of dry-cleaning in ——. F. Müller. Iron and Steel Inst., May, 1914. [Advance proof.]

An account of the dry process for the purification of blast-furnace gas (this J., 1911, 286; 1912, 1035), and of its progress. The first large plant started working in 1911 at the Halbergerhütte, near Saarbrücken, Prussia. In addition to this there are now in operation 12 installations in Germany, 5 in France, 4 in Belgium, and 1 in England; and in course of erection or on order, 7 in Germany, 6 in France, 4 in Russia, 2 in Belgium, and 2 in the United Kingdom.—A. S.

Zincs; Corrosion of [commercial] —— of various compositions. E. Prost. Bull. Soc. Chim. Belg., 1914, **28**, 94—99.

The presence in zinc of lead, cadmium or iron in larger proportion than usually found in refined zinc leads to increased corrosion by acids. Minute quantities of arsenic, antimony, copper or tin, especially the two former, accelerate very pronouncedly the rate of corrosion, more or less independently of the actual percentage of impurity present.—G. F. M.

Copper-tin and copper-zinc alloys; Effect of annealing on quenched ——. A. Portevin. Comptes rend., 1914, **158**, 1174—1177.

Copper-tin.—The increase in hardness produced by annealing at low temperature has been observed previously (this J., 1910, 1457) An alloy containing Cu 80·11 per cent. was quenched from 700° to 20° C., annealed at from 300° to 600° C., and examined microscopically. The chilled material showed the α and β phases out of equilibrium; after annealing, the α constituent appeared in the form of fine needles in the region occupied by β. *Copper-zinc.*—A very pure brass containing Cu 57·91 per cent. was chilled from 825°, and annealed at 400°—800° C. The hardness was increased by chilling and still more by annealing at 400° C. but decreased again at higher temperatures. The chilled metal was composed of β crystals, within which thin bands of the α-constituent formed on annealing, this structure being destroyed by coalescence at 800° C.—W. R. S.

Alloys; Electrolytic separation of —— and their metallographical and mechanical investigation. II. The copper-tin bronzes. R. Kremann, C. T. Suchy, J. Lorber, and R. Maas. Monatsh. Chem., 1914, **35**, 219—288. (See also this J., 1914, 28.)

Good deposits of bronze can be obtained from electrolytic baths containing tin and copper in the presence of potassium cyanide or of tartrates. To obtain coherent deposits of bronze foil the bath should contain at least 1 grm.-mol. of caustic soda per litre. The copper anode remains passive under such conditions, and the resulting anodic oxidation causes a deterioration in the tartrate baths, the tartrate being oxidised and the copper salt reduced. Micrographic and electromotive investigations of the deposits were made, together with determinations of hardness. Deposits from cyanide electrolytes had a much more uniform composition than those from a tartrate electrolyte, and on all grounds the former are the more satisfactory.
—W. H. P.

Lead-arsenic alloys; The solidification diagram of —— and the melting point of arsenic. W. Heike. Int. Zeits. Metallog., 1914, **6**, 49—57.

Cooling curves of lead-arsenic alloys with As up to 82·3 per cent. (atomic) gave a eutectic point at 288° C. and As

8·25 per cent. (atomic). Lead and arsenic were miscible in all proportions when molten, and yielded neither solid solutions nor chemical compounds. Extrapolation gave the melting-point of arsenic as 852° C. A space diagram in which pressure is taken into consideration, as well as concentration and temperature, is briefly discussed.—T. St.

Patents.

[*Iron-nickel*] *Alloy.* E. D. Gleason, New York, Assignor to Neu-Metals and Process Co., Long Island City, N.Y. U.S. Pat. 1,093,557, Apr. 14, 1914.

An alloy of Fe (Swedish) 80—120 (preferably 110), Ni 80—120 (90), Cu 1 and Al 4 parts.—W. E. F. P.

Furnace; Liquid fuel heated tipping —— for melting, smelting, refining, and other like purposes. S. W. Price, London. Eng. Pat. 5436, Mar. 4, 1913.

On one side of a vertical crucible furnace, mounted on trunnions, is a combustion chamber in which one or more burners are disposed so that the flame enters the furnace tangentially. Liquid fuel and compressed air or steam are supplied to the burners through flexible connections, so that the charge may be poured while the burners are in operation. From a bracket fixed to the upper part of the apparatus a pouring table is suspended, a mould upon which remains in line with the pouring spout when the furnace is tilted.—W. E. F. P.

Melting-furnace. G. Mellen, East Orange, N.J., Assignor to United Aluminium Ingot Co. U.S. Pat. 1,092,938, Apr. 14, 1914.

A reverberatory furnace having an inclined hearth which is extended at the upper end to the base of the stack and at the lower end to form a sump, adjacent to which is a receiving pot for the molten metal. Vertical shields (partitions) are disposed within the sump and pot, respectively, the space between the two being enclosed to form a refining chamber.—W. E. F. P.

Furnace; Electric —— for medium temperatures particularly for melting copper and its alloys. E. Stassano, Turin, Italy, and N. Petinot, Niagara Falls, N.Y. U.S. Pat. 1,093,494, April 14, 1914.

A closed cylindrical melting chamber, of approximately elliptical vertical cross-section and arranged with its axis horizontal, is located eccentrically within an outer envelope, the space between being filled with refractory material with the greater thickness in the lower portion of the furnace. Each electrode is enclosed in an external cylinder, and connected with a hollow rod through which water is circulated, and which can be moved longitudinally so as to control the position of the electrode. The chamber is provided with an air-lock charging arrangement, by means of which the charging hole is opened and simultaneously a funnel is brought over the hole.—B. N.

[*Open-hearth*] *Furnaces; Regenerative, reversible ——.* The Knox Pressed and Welded Steel Co. Fr. Pat. 464,808, Nov. 11, 1913. Under Int. Conv., May 16, 1913.

The cooling box inserted in an opening in the brickwork which separates the air and gas inlet ports is formed with an arched central portion of refractory material which forms the roof of the gas-inlet port. The box has a slight downward inclination, and the water-supply pipes extend from either end and have their discharge openings near the centre.—W. H. C.

Separating machines; Magnetic ——. H. H. Thompson, Aldridge, Staffs., and A. E. Davies, Hockley Heath, Warwickshire. Eng. Pat. 9725, April 25, 1913.

The separator is of the built-up drum type, the drum consisting of relatively thin discs of magnetic material placed side by side, so that discs of smaller diameter alternate with those of larger diameter, and thus form a number of annular projecting magnetic edges.—B. N.

Electroplating apparatus. T. R. Canning, Birmingham. Eng. Pat. 17,603, July 31, 1913.

The plating barrel is carried by a spindle supported upon arms so that the barrel is wholly immersed in the electrolyte, and without stopping its rotation can be raised from the plating vat and lowered into the swilling vat, or the reverse. The driving mechanism is arranged between the walls of the tank.—B. N.

Electroplating apparatus; Rotary ——. C. J. Charlton, South Benfleet. U.S. Pat. 1,093,384, April 14, 1914

Inside a conical drum, provided with supporting rings and two metal plates for closing the ends, is an inner tapered perforated drum, polygonal in cross-section, which is supported by seatings carried by the end plates of the outer drum. Metal bands are fitted around the outer drum and are connected by bolts and nuts with anodes on the inner surface of the drum. Both drums are carried on a rotating shaft, and the larger ends are closed by a metal plate which acts as the cathode and is also mounted on the shaft, a nut on a screw-threaded portion of the shaft acting against a cross-frame and pressing the metal door against a wooden lining covering a portion of the inner surface of the door.—B. N.

Aluminium and its alloys; Flux and process for purifying ——. G. Mellen, East Orange, N.J., Assignor to United Aluminium Ingot Co. U.S. Pats. 1,092,935 and 1,092,936, April 14, 1914.

A mixture of sodium chloride and sulphur is added to the molten metal, or the latter is stirred with a rod composed of this mixture, so as to cause agitation of the metal by sulphur vapour.—W. E. F. P.

Aluminium; Method of increasing the resistance [*to corrosion*] *of ——.* J. Vogelsanger. Ger. Pat. 272,043, April 22, 1913.

The aluminium is subjected to the action of an electric current in a boiling aqueous solution of alum, borax, and sodium hydroxide, and is then treated with nitric acid and lime water. Aluminium so treated is not corroded on exposure to the weather or by organic acids, and has an increased resistance to compression and to bending. —A. S.

Steel, iron, etc.; Hardening or treatment of ——. A. W Machlet, Elizabeth, N.J. U.S. Pat. 1,092,925, April 14 1914.

See Fr. Pat. 389,547 of 1908; this J., 1908, 985.—T. F.

Cementation of articles of iron, steel, and alloys of stee Process for the ——. F. Giolitti, Turin, Assignor Soc. Anon. Italiana Gio. Ansaldo Armstrong & C Genoa, Italy. U.S. Pat. 1,093,844, April 21, 1914.

See Fr. Pat. 415,985 of 1910; this J., 1910, 1314.—T. F.

Pig-iron; Method of improving ——. V. Stobie, Sheffie U.S. Pat. 1,093,892, April 21, 1914.

See Eng. Pat. 16,001 of 1912; this J., 1913, 831.—T. F.

Roasting furnaces for ores and the like. C. Gabrielli, Pa Eng. Pat. 8635, April 12, 1913. Under Int. Co April 13, 1912.

See Fr. Pat. 453,808 of 1912; this J., 1913, 795.—T. F

Metals or alloys; Treatment of —— to render them ductile malleable. Westinghouse Metallfaden Glühlampenfa G.m.b.H., Vienna. Eng. Pat. 11,017, May 9, 1 Under Int. Conv., May 13, 1912. Addition to Eng. 12,869 of 1912, dated June 7, 1911.

See Addition of May 10, 1913, to Fr. Pat. 445,208 of 1 this J., 1913, 1074.—T. F. B.

Zinc metal from zinc ores; Method of and apparatus for recovering ——. E. Herter, Leipzig-Gohlis, Germany. Eng. Pat. 16,035, July 11, 1913. Under Int. Conv., July 15, 1912.

See Fr. Pat. 460,404 of 1913; this J., 1914, 86.—T. F. B.

Gold, silver, and platinum; Process for the recovery of —— from extremely dilute solutions, particularly ocean water. E. Baur, Zürich, and O. Nagel, Vienna. Eng. Pat. 16,898, July 23, 1913.

See Fr. Pat. 460,680 of 1913; this J., 1914, 88.—T. F. B.

Ore concentration; Method and apparatus for ——. E. H. Nutter, New York, and T. J. Hoover, Assignors to Minerals Separation, Ltd., London. U.S. Pat. 1,093,463, April 14, 1914.

See Eng. Pat. 23,949 of 1910; this J., 1912, 31.—T. F. B.

Ovens [for ores, etc.]. Eng. Pat. 8505. *See* I.

XI.—ELECTRO-CHEMISTRY.

Tantalum electrodes; Use of ——. O. Brunck. Chem.-Zeit., 1914, **38**, 565—566. (See also this J., 1912, 1135.)

Wegelin (Chem.-Zeit., 1913, **37**, 989) obtained better deposits of zinc and copper on a platinum wire gauze cathode than on one of perforated sheet tantalum. This, however, is to be attributed to the different forms of the electrodes, for with an electrode of tantalum wire gauze, deposits were obtained equal in quality to those obtained with a platinum gauze cathode under similar conditions. Oesterheld (this J., 1913, 833) found that tantalum cathodes became brittle in use. This is true, however, only when relatively high current densities are used, and does not apply to electro-analytical operations, where current densities of 1—2 ampères per sq. cm. are usually employed.—A. S.

Patents.

Electrodes. F. Krupp A.-G., Essen, Germany. Eng. Pat. 6055, March 10, 1914. Under Int. Conv., April 15, 1913.

The carbon electrode is provided with a water-cooled metallic head, which has a conical bearing surface and rests in a metallic support, to which the conductor for the current is attached. The electrode is kept in place by its own weight.—B. N.

Electrodes in electric arc furnaces; Protecting the ——. J. I. Bronn and W. Schemmann, Lothringen, Germany. Eng. Pat. 29,259, Dec. 18, 1913. Under Int. Conv., Dec. 18, 1912.

Incombustible gases, air, water vapour, or mixtures of these, are delivered from slits or nozzles against the electrodes at or above the points where they enter the furnace, and a gas pressure, in excess of that in the furnace, is created for preventing the escape of furnace gases or flames. The steam may be generated or superheated by the radiant heat from the furnace.—B. N.

Cathode for electrolytic furnaces. G. O. Seward, East Orange, N.J., and F. von Kügelgen, Holcombs Rock, Va., Assignors to Virginia Laboratory Co., New York. U.S. Pat. 1,092,178, April 7, 1914.

The furnace, for the separation of metals lighter than their fused salts, comprises a central cathode, an outer anode, and an intermediate annular insulating diaphragm, within which the metal floats on the electrolyte in electrical contact with the upper part of the cathode. The latter is provided with a surrounding skirt projecting downwards, which separates the cathode from the electrolyte except at its upper part, and the current therefore flows in opposite directions in the inner and outer portions, thus minimising the magnetic or inductive effects.—B. N.

Electrodes; [Active material for] Storage battery ——. H. C. Hubbell, Newark, N.J. U.S. Pat. 1,092,267, April 7, 1914.

Nickel oxide is briquetted, then heated in a reducing atmosphere, and, without substantial exposure to air, immersed in an alkali solution. The damp material is ground, dried, mixed with nickel hydroxide or its equivalent, and again briquetted.—B. N.

Furnace; Electric ——. J. W. Brown, Lakewood, Ohio, Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,093,382, April 14, 1914.

The furnace, provided with heating electrodes, is divided into an outer, an intermediate and an inner vertical channel, through which the charge is passed successively in alternate directions, so that the material in the outer channel forms a heat-absorbing envelope.—B. N.

Furnace; Electric ——. R. S. Bicknell, New York. U.S. Pat. 1,093,968, April 21, 1914.

The furnace, of the resistance type, is provided with a number of branched non-metallic resisters, each of which has more than two electrodes, and which are so arranged that, by changing the path of the current, the resistance of that portion of the circuit comprised by the resister is raised or lowered.—B. N.

Furnace; Electric —— and process of heating substances uniformly and at a controllable temperature in an electric arc. E. F. von Wilmowsky, Boston, Mass., Assignor to O. Pieper, Potsdam, Germany. U.S. Pats. 1,094,354, 1,094,355, and 1,094,381, April 21, 1914.

(1) Parallel electrodes, provided with mechanical supports at both ends, are arranged concentrically with an air gap of considerable width between them, and are surrounded by the turns of a solenoid. Each electrode is provided with a divided circuit, connected to each of the ends, and means are provided for supplying the branches of each circuit with pulsating currents of substantially one and the same periodicity, for controlling the electric discharge. (2) An electric arc is established between electrodes located in a substantially uniform magnetic field, and transverse to the flux of the same, thus spreading the arc; the current of gas to be treated is passed through the furnace in contact with the arc. (3) Concentric cylindrical electrodes, with means for producing an arc between them, are spaced apart, the intermediate space forming the furnace chamber, and a solenoid is arranged so that its magnetic axis coincides substantially with that of the electrodes. Independent regulators are in electrical circuit with the electrodes and solenoid respectively, and by means of carbon pencils, movable through the outer electrode towards and from the inner electrode, the current may be supplied at different levels to the outer electrode. Means are provided for closing the upper and lower ends of the furnace chamber, and for continuously feeding material through it.—B. N.

Brush for dynamo-electric machines. E. G. Gilson, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,093,614, April 21, 1914.

The brush comprises a moulded mass of metallic particles consolidated by heating, and contains copper, an alloying metal softer than copper, such as tin, graphite, as a lubricant, and 2 to 5 per cent. of iron.—B. N.

Gases; Production of —— by electric arc. R. Haddan, London. From International Ionizing Process Co., Wilmington, Del., U.S.A. Eng. Pat. 8033, April 5, 1913.

See Fr. Pat. 463,728 of 1913; this J., 1914, 427.—T. F. B.

Electrical furnaces; Process of heating ——, more particularly applicable to the manufacture of aluminium nitride. Soc. Générale des Nitrures, Paris. Eng. Pat. 24,347, Oct. 27, 1913. Under Int. Conv., Dec. 14, 1912.

See Fr. Pat. 463,390 of 1912; this J., 1914, 427.—T. F. B.

Electric induction heater or furnace. A. Helfenstein Vienna. U.S. Pat. 1,093,328, April 14, 1914.

See Eng. Pat. 14,164 of 1912; this J., 1913, 432.—T. F. B.

Process of making chlorates and apparatus therefor. U.S. Pat. 1,092,369. *See* VII.

Electrolytic production of alkali, using a mercury cathode. Ger. Pat. 272.476. *See* VII.

Treatment of liquids [oils, etc.] by nascent ozone. Eng. Pat. 8772. *See* XII.

Process of making catalysers [for hydrogenating fats]. U.S. Pat. 1,092,206. *See* XII.

Process for producing 1.3-diols. U.S. Pat. 1,094.224 *See* XX.

Process for producing 1.3-glycols. U.S. Pats. 1,094,315 and 1,094,316. *See* XX.

XII.—FATS; OILS; WAXES.

Linseed oil; Detection of "gloss oil" [rosin oil] in ——. A. Thurston. Oil, Paint, and Drug Reporter, Apr. 20, 1914, 50.

The Liebermann-Storch reaction will not detect 50 per cent. of "gloss oil" from rosin in linseed oil. Concentrated nitric acid (one drop added to 4 or 5 drops of the oil) gives a more reliable reaction. Pure "gloss oil" gives a violet-red tint changing to violet-red, and the colour given by mixtures of linseed oil with 50 per cent. of "gloss oil" is equally pronounced. Mixtures containing from 5 to 25 per cent. of the rosin oil give yellow to greenish-yellow colorations after standing for a few seconds.—C. A. M.

Almond and apricot kernel oils; Acidity of ——. J. C. Umney. Perfum. and Essent. Oil Rec., 1914, **5**, 101—102.

The acidity of 23 samples of almond oil varied from 0·6 to 9·2 per cent. (calculated as oleic acid). An oil of high acidity was found to be satisfactory in odour and taste after keeping for six months. The range of acidity for 34 samples of peach and apricot kernel oils was from 0·6 to 5·97 per cent. After the apricot kernel oil with the highest acidity had been kept for 12 months, the odour and taste were very unsatisfactory. The oils examined had been pressed in England or France.—F. Shdn.

Oil-nut from the Philippines. Cocoanut oil industry. Oil, Paint, and Drug Rep., April 27, 1914. [T.R.]

The Bureau of Science of the Philippine Government at Manila is investigating a new oil-bearing nut that has been discovered on the island of Catanduanes, whence the nuts were forwarded by natives under the impression that they were candle-nuts. The nuts so far have not been exactly identified, though the bureau reports that they belong to the family *Meliaceae*, genus *Amoora* or *Dysoxylum*. The dry nuts yield 45 per cent. of a dark, fatty oil that makes a good commercial grade of soap. It is of a non-drying character and is said also to be unsuited for edible purposes.

The manufacture of cocoanut oil from Philippine copra at Manila has come to the front rapidly in the last year or so. The exports of the oil from the Philippines in 1912 amounted to 1,450 pounds, valued at $40 gold; the exports in 1913 amounted to 11,022,064 pounds, valued at $1,146,339.

Oleic acid; Action of halogens on —— and determination of iodine values of oils. W. Meigen and A. Winogradoff. Z. angew. Chem., 1914, **27**, I., 241—244.

The Wijs method of determining the iodine values of oils is considered to be the best on account of its rapidity and because the formation of substitution products is inhibited by the hydrogen ions of the acetic acid. Of the different reagents, the Waller modification of Hübl's solution retained its strength best on keeping; a solution which required (per 25 c.c.) 47·6 c.c. of $N/10$ thiosulphate when freshly made required 40·5 c.c. after keeping for one year. The action on oleic acid of chlorine, bromine, and iodine, separately and in admixture with each other was studied. Chlorine reacted most and iodine least energetically. When chlorine and iodine in equivalent proportions were used more chlorine than iodine was absorbed; chlorine showed a greater tendency towards substitution. The formation of hydrogen halides is due only to substitution. When the iodine value of an unknown substance is to be investigated, the use of a chlor-iodine solution in carbon tetrachloride is recommended, as the amount of substituted halogen can be estimated by extracting the hydrogen halide with water and titrating with standard alkali.—R. G. P.

Soap solutions; Studies of the constitution of ——. Alkalinity and degree of hydrolysis of soap solutions. J. W. McBain and H. E. Martin. Chem. Soc. Trans., 1914, **105**, 957—977. (See also this J., 1914, 323.)

The degree of hydrolysis and true alkalinity of soap solutions was determined by measuring the electromotive force, a hydrogen electrode being used. The dissociation of water under these conditions at 90° C. was calculated as $69{\cdot}7 \times 10^{-14}$. The hydrolysis of concentrated soap solutions was a fraction of 1 per cent., and was only 6·6 per cent. in the case of 0·01 N solutions of sodium and potassium palmitates. Hence, the high electrical conductivity of soap solutions is not due to free alkali. The alkalinity of soap solutions was not appreciably reduced by the addition of free palmitic acid (one equivalent): whilst the alkalinity of solutions containing an excess of alkali was practically that of the added alkali. Apparently there was no formation of basic soap in the presence of 0·1 N alkali. In the presence of sodium chloride the alkalinity was first decreased and then again increased. All the samples of commercial soaps examined gave alkaline solutions, the toilet soaps to a greater extent than the household soaps, but in each case the alkalinity was less than that of the sodium palmitate solutions. The low alkalinity of the soap solutions indicates that the detergent action of soap is physical rather than chemical, and this view is supported by the fact that Reychler's "hydrogen soap" (hexadecylsulphonic acid) (Kolloid. Zeits., 1913, **12**, 277), where hydrolysis is out of the question, has detergent powers.—C. A. M.

Patents.

Ozone; Treatment of liquids [oils, etc.] by nascent ——. A. Breydel, Brussels. Eng. Pat. 8772, April 14, 1913.

The ozoniser is disposed in a vessel containing the material to be treated, such as oils, liquid greases and fats or the like. A hollow electrode is provided with small orifices, so that the air or oxygen is discharged opposite to a second electrode in such a manner that the nascent ozone is utilised at the surface of the electrode, whilst at the same time the gas agitates and mixes the liquid to be treated. If necessary, an auxiliary ring or coil may be used to inject air, with the object of aerating and further agitating the liquid.—B. N.

Fats; Process for melting animal and vegetable ——. W. McDonnell, Limerick. Eng. Pat. 8784, April 14, 1913.

The fat is melted in a jacketed pan having a perforated false bottom covered with a cloth to serve as a filter, the separation being promoted by revolving beaters. (Reference is directed to Eng. Pat. 5235 of 1879.)—C. A. M.

Catalysers [for hydrogenating fats]; Process of making —— C. Ellis, Montclair, N.J. U.S. Pat. 1,092,206, April 7 1914.

An electric current of arc-forming strength is passe between electrodes of nickel or material containing nick in presence of water or other liquid medium, and finely-divided nickel or nickel precipitate from the erosi is collected.—C. A. M.

Catalytic agents [for hydrogenating oils]; Process for regenerating —— Naamlooze Vennootschap Ant. Jurgens Vereenigde Fabr. Fr. Pat. 465,256, Nov. 24, 1913. Under Int. Conv., Dec. 18, 1912.

THE spent catalytic agent is heated gently to destroy organic matter, the metallic residue dissolved in acid, and the metal re-precipitated upon an inorganic basis, such as kieselguhr.—C. A. M.

Fats; Saponification of industrial —— by means of electrolysed saline lyes. L. G. A. Andrault. Fr. Pat. 464,248, Oct. 30, 1913.

THE fat is treated with electrolysed salt solution poor in soda in insufficient quantity for saponification. This will neutralise free fatty acids, with separation of the resulting soap, and the saponification is then completed by means of a second electrolysed salt lye richer in soda. The lye from the second stage will contain the bulk of the glycerin.—C. A. M.

Soap containing hydrocarbons; Manufacture of a stable ——. C. Pleines. Fr. Pat. 464,335, Oct. 31, 1913. Under Int. Conv., Nov. 6, 1912.

HYDROCARBONS are incorporated with soap containing an excess (up to 5 per cent.) of fat.—C. A. M.

Soap; Process for the manufacture of ——. A. L. Mowry, F. A. Secord, C. H. Peters, and A. P. Paterson. Fr. Pat. 464,777, Sept. 25, 1913.

MACHINERY is claimed for a rapid process of cooling and hardening the soap paste into the form of a prism, which is then cut into tablets.—C. A. M.

Soaps containing mercury; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,820, June 20, 1911.

FATTY acids of the oleic series are treated with mercuric acetate in alcoholic solution, the acetic acid residue is removed from the product by treatment with an alkali halide solution, and the resulting mercury derivative of the fatty acid is converted into its alkali salts. The soaps thus formed contain mercury in combination with a carbon atom, in which form it is not ionised.—T. F. B.

Preparing acid esters from esters lower in hydrogen. Ger. Pat. 271,985. *See* XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Colophony; Melting points of acids derived from ——. L. Paul. Chem. Rev. Fett Ind., 1914, 21, 102—105

THE acid of the constituent of colophony sparingly oluble in dilute soda solution (this J., 1914, 429), swells up and shows a rise of m. pt. (from 74°—75° C. to 103°—05° C.) in its transformation into the constituent readily oluble in soda solution. The other product previously lescribed melting at 130° to 135° C., and the acid (probbly γ-abietic acid) formed in the distillation of the onstituent soluble in petroleum spirit, are also probably econdary derivates from the decomposition of colophony e.g. in the treatment with steam to remove oil of turentine). The rapid transformation of colophony into ater-soluble constituents accounts for the want of tability of colophony varnishes on exposure to weather. —C. A. M.

PATENTS.

Distemper; Process of manufacture of a powdery medium for ——, *for both internal and external work.* F. Beckmann. Fr. Pat. 464,437, Nov. 5, 1913.

N intimate mixture of finely powdered slaked lime, 300; ugar, 150; dextrin, 150; gum arabic, 100; and magne-um sulphate, 25 parts, is moistened with water until it tains the consistence of moderately thick oil paint, and ter ten minutes is still further diluted and filtered. —E. W. L.

Condensation products from phenol, formaldehyde and the like; Process for manufacturing ——. K. Tarassoff, Moscow, Russia. Eng. Pat 528, Jan. 8, 1914.

CONDENSATION products, which although hard, are less brittle than bakelite and similar products, are obtained by the action of aldehydes such as formaldehyde, upon mixtures of phenols with sulphonated fats and oils, as, for instance, sulphonated castor-oil, prepared by treating 100 parts by weight of oil with 30 parts of sulphuric acid (sp. gr. 1·842), and washing the product with water and a solution of common salt. For example, 200 parts of commercial carbolic acid are mixed with 50 parts of sulphonated castor oil, 130 parts of 40 per cent. formalin, and 200 parts of water acidified with sulphuric acid. The mixture is stirred and heated until the reaction begins. The resinous mass obtained is washed with water and with a solution of sulphur dioxide in order to keep it colourless. About 300 parts of a white opaque, fusible product are obtained.—E. W. L.

Phenolic condensation products; Process of comminuting ——. J. W. Aylsworth, East Orange, N.J. U.S. Pat. 1,092,512, Apr. 7, 1914.

THE components of the condensation product are dissolved in a suitable solvent and heated so as to cause interaction without allowing the solvent to escape. This causes the resulting condensation product to contain pores filled with solvent, which facilitate its subsequent comminution. —C. A. M.

Lacquers; Process of manufacture of solutions or ——. Chem. Werke vorm. H. Byk. Fr. Pat. 464,617, Nov. 3, 1913. Under Int. Conv., Nov. 8, 1912.

ESTERS of lactic acid, particularly ethyl lactate, are employed as solvents for nitrocellulose and other cellulose esters such as the acetate and formate, as also for certain resins such as copal, sandarac and colophony, in the preparation of lacquers. Such solutions may be diluted with liquid hydrocarbons, more particularly those of the aromatic series, halogen derivatives thereof, ethers, acetone, alcohols, and mixtures of these solvents. For example, 10 parts by weight of acetylcellulose may be dissolved in a mixture of 50 parts by volume of ethyl lactate and 30 parts of benzene; or 50 parts of ethyl lactate, 30 parts of trichloroethylene and 20 parts of alcohol.—E. W. L.

Lampblack obtained by decomposing hydrocarbons or hydrocarbon mixtures; Process for freeing —— from gaseous admixtures. K. Bosch. Ger. Pat. 271,901, Feb. 28, 1913.

THE lampblack is carried from the decomposition chamber through heated tubes to a vessel in which it is vigorously centrifuged; it is then passed through a second heated tube to a suitable receptacle. A pulverulent product, free from mechanically combined gases, is obtained.—T. F. B.

Printing-ink; Process of making ——. M. Wolff, London. U.S. Pat. 1,094,283, April 21, 1914.

SEE Eng. Pat. 30,037 of 1912; this J., 1913, 1162.—T. F. B.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

PATENTS.

Rubber from hydrocarbons; Process of preparing —— resembling —— from animal or vegetable colloids or albuminoids by treatment in vacuo with or without the addition of other materials; W. Plinatus. Fr. Pat. 465,047, Nov. 18, 1913.

1.3-BUTADIENE (erythrene) or a homologue thereof, such as isoprene, is saturated with dry aqueous ammonia and subjected to heat and pressure.—A. S.

Elastic substances [artificial rubber]; Process of preparing ——. R. B. Earle, Cambridge, Mass., Assignor to Hood Rubber Co. U.S. Pat. 1,094,317, April 21, 1914.

1.3-BUTADIENE (erythrene) or a homologue thereof is mixed with 1—3 per cent. of a higher fatty acid, heated in a closed vessel at 100°—120° C. until the mass solidifies (1—3 weeks), and any unchanged hydrocarbon and by-products removed by distilling with steam.—A. S.

Rubber, horn and ivory ; Process of manufacture of products resembling —— from animal or vegetable colloids or albuminoids by treatment in vacuo, with or without the addition of other materials. W. Plinatus. Fr. Pat. 465,047, Nov. 18, 1913.

The incorporation of gelatin, on the one hand, or of casein and albumin, on the other, with other ingredients—water, glycerin, etc.—necessary for the production of soft or hard masses resembling rubber, horn and ivory, may be effected much more completely in a partial vacuum, with the result that subsequent segregation of the constituents is prevented, whilst the masses obtained are free from water and from air-bubbles. The addition of subsidiary ingredients such as camphor, resins, fats, oils, waxes, tar, asphaltum, rubber and reclaimed rubber, cellulose esters, starch, dextrin, sulphur and various mineral fillers, may take place either before or during the treatment *in vacuo* ; and the product may be hardened subsequently by means of the usual hardening agents.—E. W. L.

Elastic or plastic masses ; Process for the preparation of ——. J. Stockhausen. Fr. Pat. 465,306, Nov. 25, 1913. Under Int. Conv., Dec. 20, 1912.

An intimate mixture of gelatin, 125 ; glycerin, 125 ; camphor, 5 to 20 ; sulphur ; and colophony, 10 to 50 grms., is heated for several days, and 4 per cent. formaldehyde, 10 to 20 ; or sodium bichromate, 3 to 10 grms. is then incorporated with it.—E. W. L.

Process of producing isoprene. U.S. Pats. 1,094,222 and 1,094,223. *See* XX.

XV.—LEATHER ; BONE ; HORN ; GLUE.

Willow barks ; Classification of —— by means of chemical reactions. G. Powarnin and A. Barabanow. Collegium, 1913, 276—282.

The experiments were made with extracts prepared from barks of 34 Russian willows (22 pure varieties and 12 hybrids). The general reactions were : dark brown precipitate with copper acetate, with barium hydroxide, and, with the exception of *S. viminalis*, with calcium hydroxide ; brownish yellow precipitate changing to brownish green with lead acetate ; brown ring, colouration and precipitate with concentrated sulphuric acid ; light red to yellow precipitate with formaldehyde and hydrochloric acid ; light brown colouration with silver nitrate ; brown colouration with nitrous acid ; light red stain on a pine chip (this fails in some cases) ; yellowish red to brown precipitate with quinine hydrochloride ; green to brownish green colouration with ammonium vanadate ; yellow to cherry-red precipitate with concentrated hydrochloric acid ; lemon yellow to orange precipitate with bromine water ; yellow to brown colouration with sodium molybdate. The reactions of the tannins from the different varieties are tabulated, and these allow of the division of the barks from the pure varieties into two groups characterised by giving (1) an immediate precipitate with copper sulphate and ammonia, a violet colour with ferric chloride, and a cherry-red to violet colour with gold chloride : *S. viminalis* is typical of this group ; (2) no precipitate at first with copper sulphate and ammonia, a green colour with ferric chloride, and a brown colour with gold chloride : a typical member of this group is *S. purpurea*. Characteristic for certain varieties are : *S. viminalis*, a white precipitate, gradually turning brown, with calcium hydroxide ; *S. pentandra*, a green colour with ammonium molybdate ; *S. babylonica* light brownish green, *S. repens* dark green and *S. lanata* dirty green with sodium tungstate ; *S. Lapponum* pink, *S. purpurea* greenish yellow, *S. pentandra* yellow, and *S. Wiegeliana* dark brown with disodium phosphate. The reactions show that the willows contain two classes of tannin. The barks from the hybrids gave in general reactions representing the combined effects of the tannins of the pure varieties from which the hybrid had been bred.—A. S.

Tannin of the bark of Salix alba × viminalis. G. Powarnin and N. Schurawlew. Collegium, 1913, 283—291.

The bark of *Salix alba* × *viminalis* contains, in addition to phlobaphenes, two tannins giving different reactions with copper sulphate and ammonia and with ferric chloride (see preceding abstract). The one tannin (from *S. viminalis*) may be separated from the other (from *S. alba*) by fractional precipitation of a methyl alcohol solution with ether. The tannin of *S. alba* is a yellow or white tannoside, which yields anhydro- and oxy-phlobaphenes, and on hydrolysis yields protocatechuic acid. *S. viminalis* contains free sugar ; its tannin yields pyrogallol on hydrolysis. It is noted that in the analysis of tanning materials both free and combined sugar should be determined.—A.S.

Tanning materials ; Pentoses in ——, and the detection of mangrove. H. C. Reed and A. Schubert. J. Amer. Leather Chem. Assoc., 1914, **9**, 131—135 (See also this J., 1914, 151, 152.)

The yellow colour followed by a red precipitate produced by adding phloroglucinol to the hydrochloric acid distillate is not necessarily an indication of the presence of methylfurfural since other aldehydes, such as formic, acetic and anisic, give the same reaction. Filter paper steeped in aniline hydrochloride gives, with furfural, an immediate cerise colouration whilst with methylfurfural it gives a yellow colour turning brick red, with anisaldehyde a yellow not turning to crimson, with acetaldehyde and formaldehyde no colouration, and with paraldehyde a crimson colouration. Pentoses, pentosans and methylpentoses may be formed during the distillation with hydrochloric acid by hydrolysis of glucosides and other substances present in tanning extracts. Furfural is a general decomposition product of carbohydrates, and methylfurfural which is formed by the hydrolysis of rhamnose with dilute acids is produced when substances are present which yield rhamnose by the action of acids : quercetrin, sophorin (from blackthorn berries), xanthorhamnin, hesperidin and frangulin yield rhamnose under these conditions. This may also introduce an error in the determination of sugar in tanning materials, since the sugars present as ascertained by hydrolysis include the sugars formed in the operation itself and not naturally present as such ; xylan, for example, yields xylose, which reduces Fehling's solution. In distillation tests with hexose sugars, reactions, with the phloroglucinol test, similar to those from the pentose and methylpentose sugars were obtained. Dextrose in large amount gave the methylfurfural reaction, in small amount, a negative test ; lævulose in all cases gave a negative test The following extracts gave the furfural reaction with phloroglucinol : quebracho, myrobalans, sulphite-cellulose, sumac and chestnut. Gambier gave a drab precipitate with a colourless solution, showing absence of pentose or methylpentose sugars or of glucosides or other materials yielding these by hydrolysis. The precipitate obtained with phloroglucinol and the distillate from mangrove extract was not of the distinct brick-red colour given by the methylfurfural phloroglucide obtained from rhamnose but was of a brown colour. The character and method of extraction of the mangrove bark had an influence on the colour obtained by the test. Methylpentoses or compounds forming them were apparently more readily extracted than were pentoses or furfural-forming compounds. Quercitron or black oak bark containing quercitrin which yields rhamnose on hydrolysis gave th methylfurfural test similarly to mangrove, as did als cutch. The value of the proposed test for distinguishin mangrove is open to doubt.—D. J. L.

Tanning materials in admixture ; Determination of —— R. H. Wisdom. J. Amer. Leather Chem. Assoc., 191 **9**, 136—139.

Solutions of the strength used in the official methods analysis were prepared from different extracts and 200 c. of each were shaken with 5 grms. of pure degummed boiled-off silk, allowed to stand overnight, and the si squeezed and dried. Each extract produced a distincti colour on the silk and various makes of the same materi varied little from the standard for that material. Furth evidence for identification was obtained by dipping pieces of the impregnated silk in solutions of reagents, allowing the colour to develop, washing and comparing the resulting colour with the standard. The colour produced by lime water on silk previously impregnated with mangrove extract was characteristic and shown by no other material tested.—D. J. L.

Tanning purposes ; Water and its purification for ——. M. F. Corin. J. Amer. Leather Chem. Assoc., 1914, 9, 143—158.

Water for tannery use should be free from turbidity and contamination, soft and free from iron. To remove turbidity and bacteria, the best coagulant for tanners' use is aluminium sulphate, added as a 3—5 per cent. solution ; when there is not sufficient alkalinity in the water to precipitate all the alum, slaked lime or soda is previously added. Hard water is less objectionable when used for unhairing purposes than in any other part of the tannery, but when sodium sulphide alone is used, a proportionate waste of that material is caused. For soaking, washing and bating purposes and in the yard and leach house, temporary hardness is a great disadvantage. If a hide is transferred from a lime liquor to water high in calcium bicarbonate, lime becomes fixed in the hide as carbonate, causing rough grain and stain and discolouration in the tan liquors. For neutralising temporary hardness, an acid which forms an easily soluble calcium salt and which has no effect on the liquors if used in excess, is preferable, such as lactic or acetic acid. Hardness is very objectionable in making up fat-liquors. For each German degree of hardness (17 parts per million) 1¼ lb. of soap will be wasted for every 1000 galls. of water used. Lime soaps adhere to the leather and cause trouble in the glazing. The efficiency of water-softening plants using slaked lime, and alkalis, is greatly increased by heating the water slightly by means of exhaust steam. Water entirely free from hardness and low in sodium carbonate can be obtained by first applying the chemical process followed by the "Permutit" process. Any iron present may be removed by use of manganese-permutite (a zeolite in which sodium has been replaced by manganese by treatment with manganese chloride and permanganate solutions) whereby it is completely oxidised and retained as hydroxide on the filter.—D. J. L.

Reversible transformation of gum and gelatin from the emulsoid into the suspensoid condition. Scarpa. *See* XVII.

Patents.

Leather ; Process of colouring artificial ——. E. Girzik, Vienna. Eng. Pat. 4668, Feb. 23, 1914. Under Int. Conv., Dec. 18, 1913.

A solution of say 10 kilos. of nitrocellulose in one of the known solvents, is mixed with softening oils and with about 5 kilos. of aluminium hydroxide, spread, in one or more layers, on one side of an undyed cotton fabric, and allowed to dry. The fabric is then dyed in an acid bath with a basic aniline dye.—E. W. L.

Leather substances ; Method of manufacturing ——. C. Rössler, Hamburg. Eng. Pat. 19,787, Sept. 1, 1913. Under Int. Conv., Sept. 2, 1912.

Leather or leather waste is ground with granular non-fibrous substances (*e.g.*, magnesium oxide, kieselguhr, metallic pigments or organic substances) and treated with a binding agent (*e.g.*, solution of magnesium chloride or sulphate, tar oils or mineral oils, etc.). For example the ground product may be mixed with glycerin and slaked lime, and then with linseed oil as binding agent. Substances thus obtained may be made into plates or slabs, or used in the production of jointless floors.—C. A. M.

Leather ; Process for graining and rendering impermeable split, inferior and weak ——. C. Krug and H. Böllert. Fr. Pat. 464,842, Nov. 12, 1913. Under Int. Conv., April 16, 1913.

The leather is dried in a vacuum, treated with a solution of resin in carbon bisulphide, alcohol, ether, amyl alcohol, petroleum spirit, benzene acetone or ketones or mixtures of these, and then exposed to formaldehyde vapour under diminished pressure.—D. J. L.

Chrome tanning ; Process for ——. F. Hirsch. Ger. Pat. 271,585, March 13, 1913.

The chromic acid solution is reduced by means of aluminium bisulphite or zinc bisulphite, or a mixture of the two, without addition of acid ; retardation of reduction may be adjusted by addition of an acid or of an alkali or alkaline-earth bisulphite together with an acid. When aluminium bisulphite is used, aluminium hydroxide is precipitated in the hide, and the advantages of a basic tannage are obtained in addition.—T. F. B.

Glue [*Vegetable*] *; Manufacture of* ——. Perkins Glue Co. Third Addition, dated Oct. 28, 1913, to Fr. Pat. 436,297, Nov. 11, 1911. (See this J., 1913, 761.)

A vegetable glue having the required properties of viscosity, cohesion and adhesion is prepared by mixing a product of very high viscosity with one or several carbohydrates of lower viscosity. For example it may be made from a mixture of starches, one of which has been treated too long or too strongly with oxidising or hydrolysing agents and another which has not been treated sufficiently to produce a good glue.—D. J. L.

Horn or ivory ; Manufacture of products similar to —— *from albuminous materials and neutral or acid esters of higher alcohols.* W. Plinatus. Fr. Pat. 465,048, Nov. 18, 1913.

Albuminous substances of animal or vegetable origin, *e.g.*, albumin or casein or their derivatives such as the alkali albuminates, are treated with neutral or acid esters of higher alcohols or amino-fatty acids. The albuminous matter becomes hard and coagulated and is subsequently mixed with organic materials such as resins, sulphur, camphor, pitch, paraffin, oils, rubber or cellulose derivatives in suitable solvents.—D. J. L.

XVI.—SOILS ; FERTILISERS.

Soils and kaolin ; Adsorption phenomena in ——. J. E. Harris. J. Phys. Chem., 1914, 18, 355—372.

Evidence is brought forward in favour of the view that the acidity of soils, at any rate of those of the sandy loam type, is not due to insoluble organic acids of the nature of humic acid, but to the selective adsorption of bases from the salts in the soil solution, the solution being thus left acid. The amount of base adsorbed on treating such a soil with a neutral salt depended on the salt used, being greater for sodium acetate than for potassium nitrate and sodium chloride. When a soil was treated several times with each of these salt solutions the differences in their acidity became greater with each application. Preliminary treatment with dilute acid, followed by thorough washing, increased the power of a soil to liberate acid from salts, presumably because the originally adsorbed base was removed by the acid, thus allowing the soil to adsorb much more : the effects produced by $N/2$ and $N/80$ sulphuric acid were almost identical. Kaolin in its natural condition did not affect a salt solution, but after treatment with acid and washing, it behaved in just the same way as a soil towards neutral salts. The effect of acid on the kaolin varied with the concentration, which indicates that its action consisted, not in neutralising adsorbed basic material, as in the case of soil, but in rendering some of the silicates colloidal and capable of adsorbing bases. In no case was the acid merely adsorbed by the soil or kaolin and then liberated on treatment with a salt. Using barium chloride as the neutral salt the base was adsorbed in quantities practically equivalent to the amount of acid liberated. After boiling with concentrated sulphuric acid for seven hours to remove all organic matter, and then washing out all the acid, the soil was still capable of liberating as much acid from a salt solution as a soil which had only been treated with $N/20$ sulphuric acid. This shows that in such soils the adsorbing agent is probably a hydrated silicate and not organic matter. —W. H. P.

Soils ; Occurrence and nature of carbonised material in ——. O. Schreiner and B. E. Brown. Bull. U.S. Dept. Agric., Bureau of Soils, No. 90, Dec. 1912.

The coarser fractions of well disintegrated soil were subjected to elutriation first with mixtures of bromoform and carbon tetrachloride and then with water, to separate and roughly fractionate the lighter organic material. This was separated by a process of mechanical assortment, aided by the lens or microscope, into the following types : (1) plant material and (2) animal material, both of organised structure, (3) charcoal particles, (4) lignite particles, (5) coal particles, and (6) other materials some of which suggest intermediate formations. All these types probably exist in finer subdivision in the finer fractions of the soil. The coal and charcoal types in particular were found in all kinds of soil, in ordinary subsoils and in samples collected at depths of 15 to 50 feet below the surface. A relatively large fraction of soil organic matter may consist of these resistant forms, which would become available only with extreme slowness. An analytical method depending on graded or moderated oxidation which would give some indication of the availability of the organic matter is desirable. The wide occurrence and the characteristic appearance and nature of the various particles suggest their actual formation in the soil to some extent. —W. H. P.

Soils ; Action of manganese in ——. J. J. Skinner, M. X. Sullivan, J. H. Beattie, F. R. Reid, and H. Winckelmann. Bull. U.S. Dept. Agric., Bureau of Soils, No. 42, Apr. 3, 1914.

In pot experiments with wheat in a poor soil, manganese salts in the proportion of 5 to 50 parts per million had a stimulating effect, larger quantities being often injurious. In a good soil no stimulating effect was observed. Wheat was also grown in aqueous extracts of the soils and the oxidising power of the roots tested by adding aloin solution in the last two days of growth, the extent of the change from pale yellow to red being measured colorimetrically. The manganese always improved the oxidising power of the roots. In extracts from poor soils this led to increased growth, and in some cases to the removal of harmful organic compounds which probably were the cause of retarded oxidation in the untreated extracts. In extracts from good soils the stimulated oxidation appeared to be excessive, and the growth was consequently diminished. In a five-year field test on a silty clay loam soil of acid character, 50 lb. of manganese sulphate per acre had a harmful effect on wheat, rye, maize, cowpeas, and potatoes, and decreased the already low oxidising power of the soil. The catalytic power of the soil as measured by the rate of decomposition of hydrogen peroxide was only slightly if at all increased. These effects may be due to the acid character of the soil, and treatment with manganese salts is not suitable for a soil of such a nature which is in need of liming.—W. H. P.

Bacterial action in soils as a function of food concentration and of insoluble organic matter. O. Rahn. Zentr. Bakt. u. Parasitenk., II. Abt., 1913, **38**, 484—494. Expt. Stat. Record, U.S. Dept. Agric., 1914, **30**, 217—218.

From experiments with sand of different degrees of fineness, it was concluded that bacterial activity in soils depends upon the size of grain, water content, and concentration of nutrient substances. In the decomposition of peptone by *Bac. mycoides* the final reaction product was always the same for a given concentration of nutrient material, only the speed of decomposition varying with the size of grain and water-content of the soil : in other cases both the speed of decomposition and the final product were affected by the last-named factors. In relatively dry soils, spongy organic substances, such as cellulose, had a dehydrating effect and diminished bacterial action, but in wet soils they promoted ventilation and hence increased the activity of aerobic bacteria.—A. S.

Partially sterilised soils ; Growth of plants in ——. E. J. Russell and F. R. Petherbridge. J. Agric. Sci., 1913, **5**, 248—287.

The growth of plants in partially sterilised soils showed the following important differences from that in untreated soils. Germination was generally retarded, but occasionally there was a partial acceleration affecting some of the seeds only. There was generally an acceleration in growth up to the appearance of the third or fourth leaf, but some times, especially in soils heated to 100° C., a marked retardation. The retardation was on the whole more frequent during dull winter days than in brighter weather and was accompanied by a dark leaf colour, and either a purple pigment or a tendency for the leaves to curl downwards, the whole suggesting an attempt on the part of the plant to reduce assimilation. Later on the pigment disappeared and the curling ceased. Growth became rapid and proportional to the plant food present. Plants grown in soils heated to 100° C. showed a very remarkable fibrous root development and had larger leaves of deeper colour, stouter stems and shorter internodes. They flowered earlier and more abundantly and their dry matter contained a larger percentage of nitrogen and sometimes of phosphoric acid. The roots and stems gave up their mineral food constituents more completely to the fruit. Plants grown on soils heated to 55° C. or treated with volatile antiseptics showed fewer of these effects. There was only rarely retardation in seedling growth, but usually an acceleration, sometimes a rapid one, followed by steady growth. No special root development or shortening of internodes occurred but there was a marked improvement in the percentage of nitrogen and phosphates in the dry matter, and in the translocation of these materials to the fruit. The principal chemical difference was that in partially sterilised soils ammonia accumulated and nitrates were absent. The aqueous extract of the partially sterilised soil was much richer in nitrogen than that of untreated soils. Soils heated to 100° C. contained decomposition products which dissolved in water to a brown solution. Some of these products proved specially suited for the nutrition of certain moulds. —W. H. P.

Experiments on the rate of nitrification. Beesley. *See* XIXB.

Patents.

Superphosphate ; Apparatus for use in the manufacture of ——. G. H. Lynen, Passaic, N.J. U.S. Pat. 1,093,141, April 14, 1914.

A movable platform is introduced into the superphosphate chamber and engages adjustable walls therein, so as to form a receptacle for the material to be removed. Means are provided for subsequently withdrawing the walls and passing the platform beneath an unloading device outside the chamber.—F. Sodn.

Fertiliser from silicious, potassium-bearing rocks and minerals containing phosphoric acid ; Process of producing a ——. Chem. Fabr. Rhenania and A. Messerschmitt. First Addition, dated Oct. 14, 1913, to Fr. Pat. 462,357, Aug. 13, 1913 (this J., 1914, 327).

The lime used as described in the chief patent (*loc. cit.*) may with advantage be partly replaced by alkali, *e.g.* sodium carbonate, and the process may be carried out in two stages, the silicious rock (*e.g.* leucite) being calcined with 30 per cent. of lime, and the resulting double silicate of lime and potassium finely pulverised and heated with the ground phosphatic mineral to incipient fusion. The use of 5 to 10 per cent. of sodium carbonate facilitates the progress of the reaction.—E. W. L.

Fertilisers obtained by means of chemical reactions an compounds, for use either as simple fertilisers, or, i admixture, as complete manures. E. T. Aucher. Fr Pat. 464,285, Oct. 8, 1913.

An aqueous solution of 200 kilos. of ferrous sulphate i added gradually, with constant stirring, to milk of lim containing 100 kilos. of lime. The mixture is allowed t stand for several hours, the water run off through a coal dust filter, and the sediment washed twice with water, and then spread out on earthenware trays, dried in an oven at 90° C. or more, and granulated. Copper sulphate and other metallic salts capable of decomposition by alkalis may be used in place of iron sulphate; and nitrogenous, phosphatic, potash and gypsum fertilisers may be added to the residue after filtering. The fertilisers are quite harmless to vegetable life, and act not only as fertilisers but as remedies in chlorosis and other plant diseases.—E. W. L.

XVII.—SUGARS; STARCHES; GUMS.

Molasses; Extraction of sugar from cane ——, and the elimination of the reducing sugars by fermentation. L. Pellet. Intern. Sugar J., 1913, **15**, 222.

To remove reducing sugars from cane molasses, and thus cause the crystallisation of a greater amount of sucrose than would otherwise be possible, the author recommends diluting the molasses to 20° Brix, and inoculating with a yeast, which ferments the reducing sugars but not the sucrose. After fermentation at 30°—34° C., the mixture is distilled, the alcohol collected, and the extraction of the sucrose in the residue effected as in the case of beetroot molasses.—J. P. O.

Dextrose; Action of ammoniacal copper hydroxide on ——. A. Windaus and A. Ullrich. Z. physiol. Chem., 1914, **90**, 366—368.

Dextrose, which yields 4-methylimidazole when treated with certain metallic hydroxides and ammonia (this J., 1905, 515), yields imidazole-4-carboxylic acid when treated with ammoniacal copper hydroxide.—L. E.

Carbohydrates and related substances; Oxidation of —— by means of potassium persulphate. J. K. Wood and N. Walker. Chem. Soc. Trans., 1914, **105**, 1131—1140.

Aldoses are almost quantitatively oxidised by potassium persulphate in the cold, the process being greatly accelerated by small quantities of silver sulphate. Galactose, arabinose, and xylose are oxidised at about the same rate, dextrose and polyhydric alcohols more slowly, whilst ketoses and disaccharides are attacked somewhat more rapidly than the aldoses.—G. F. M.

Honey; Determination of sulphur in —— and in other materials containing much sugar. F. E. Nottbohm and H. Weinhausen. Z. Unters. Nahr. Genussm., 1914, **27**, 581—587.

In the determination of total sulphur in such substances as honey, fruit syrups and wines, correct results are obtained by treating 20 grms. of the sample in a Kjeldahl flask with 0·2 grm. of magnesium carbonate and 50 c.c. of nitric acid; when the preliminary violent action is over, the flask is heated over a spirit flame and quantities of nitric acid are added from time to time until nitrous gases cease to be evolved. The solution is then transferred to a basin, evaporated on a water-bath, the remaining nitric acid removed by repeated evaporation with hydrochloric acid, and the sulphuric acid determined in he usual way.—W. P. S.

Gum and gelatin; Reversible transformation of —— from the emulsoid into the suspensoid condition. O. Scarpa. Rend. Soc. chim., ital., 1914, [2], **5**, 375—379. Kolloid-Zeits., 1914, **14**, 210.

F alcohol be added gradually to a 2 per cent. aqueous olution of gum or gelatin, the solution becomes opalescent nd then turbid. The opalescent solutions, provided the lcohol content does not exceed certain limits, are very table and have properties resembling those of suspension-colloids, the viscosity, for example, being only slightly igher than that of aqueous alcohol of similar concentra-iou. On addition of water the solutions become clear gain, the gum solution in the cold and the gelatin solution n warming. The colloidal particles in the opalescent olutions bear a negative electric charge. Solutions of sodium, potassium, barium or ferric chlorides, potassium chromate, copper, ammonium, or ferric sulphates, hydrochloric, nitric, or sulphuric acids, or potassium hydroxide precipitate the gum, whilst mercuric chloride renders the solution clear. The gelatin solution is coagulated by mercuric or ferric chlorides, or copper sulphate, and rendered clear by sodium, potassium, or barium chlorides, potassium chromate, ammonium or ferric sulphates, nitric or sulphuric acids, or potassium hydroxide. The coagulum produced in the gum solution is, in most cases, soluble in cold water, but that produced by potassium chromate or ferric chloride is insoluble both in cold and hot water. The gelatin coagulum is soluble in hot water and has the properties of an emulsion-colloid.—A. S.

Dibenzoylglucoxylose: a natural benzoyl derivative of a new disaccharide. Power and Salway. *See* XX.

Patents.

Sugars [from sawdust]; Process of producing fermentable ——. F. E. Gallagher, Troy, N.Y., and H. S. Mork, Allston, Mass. Eng. Pat. 14,938, June 28, 1913. Under Int. Conv., July 15, 1912.

Lignocellulose, *e.g.*, sawdust, is heated with chlorine water (containing chlorine equivalent to 0·2 per cent. of the dry sawdust) or with a mixture of nitric and hydrochloric acids (in quantities equivalent to 1·13 and 1·17 per cent. respectively of the dry sawdust) for say 30 minutes at a pressure of 135 ℔. Or the sawdust is treated with chlorine at the ordinary temperature for several hours and then, without removal of the chlorine, heated with dilute mineral acid, *e.g.*, sulphuric acid in quantity equivalent to 1 per cent. of the dry sawdust.—L. E.

Process for obtaining trehalose and a vegetable acid. Ger. Pat. 271,789. *See* XX.

XVIII.—FERMENTATION INDUSTRIES.

Invertose; A thermo-stable form of ——. O. Durieux. Bull. Soc. Chim. Belg., 1914, **28**, 99—101.

When an extract of yeast was boiled the whole of the invertase was not killed, the filtered solution being still active. At 80° C. the enzyme was absorbed by, and precipitated with the coagulable proteins, and the filtered solution was inactive. Some of the invertase was, however, still undestroyed, and present in the precipitate, for by treating this with boiling water, the enzyme was restored to the liquid, and after filtration the latter was active.—G. F. M.

Invertase action; Reversibility of ——. A. Blagowestschenski. Biochem. Zeits., 1914, **61**, 446—457.

Following the lines of experiments carried out by Kohl (see this J., 1908, 825) the author studied the course of inversion of sucrose by glycerin-extracts of yeast in presence of toluene, and also the prolonged action of invertase preparations on solutions of invert sugar. He states that there is no conclusive evidence for the synthesis of sucrose by invertase. The kinetics of inversion may be expressed by the equation for unimolecular reactions. A diminution of the velocity constant towards the completion of hydrolysis, is probably due to combination of the enzyme with the hydrolytic products. When invertase preparations are allowed to act upon solutions of invert sugar, there is a possibility of some maltose (or isomaltose) being synthesised by the action of maltase which is present in some invertase preparations.—J. H. L.

Fermentations in the C_3-series. C. Neuberg and J. Kerb. Ber., 1914, **47**, 1309—1315.

In consequence of experiments showing that glyceric acid is not fermentable by living yeast, the authors reject the hypothesis of v. Lebedeff (this J., 1914, 368) that this acid is an intermediate product of alcoholic fermentation. The small quantities of acetaldehyde produced by the action of dried yeast on dilute solutions of glyceric acid (*loc. cit.*) are probably due to autofermentation of the yeast, stimulated by the presence of the acid.—J. H. L.

Amylo-process of fermentation. O. Grove. J. Inst. Brew., 1914, 20, 248—261.

THE amylo-process, which is used in many of the largest distilleries of France, Italy and Spain, is characterised by the use of mould fungi instead of malt for the saccharification of the starch and by the rigorous application of pure culture methods on a large scale. The organisms employed, originally isolated from "Chinese yeast," belong to the groups *Mucor* and *Rhizopus.* The most satisfactory one, *R. Delemar*, converts starch into dextrose and also slowly ferments the latter, but in practice a special yeast (see Will, this J., 1913, 1123) is added to effect fermentation. During saccharification the mould is kept submerged in the liquid, otherwise sporulation occurs, accompanied by oxidation of starch. In submerged cultures of the mould, sections of the filaments become detached in the form of oval cells (gemmæ) which germinate more rapidly than the true spores, so that when a very rapid saccharification is required the mash is treated with a "bub" of the mould instead of the spore culture usually employed. The principal raw materials of the amylo-process are rice, maize, manioc, dari, millet and potatoes. The method of working maize is given in detail. The starch has first to be liquefied as completely as possible For this purpose the maize is coarsely ground and agitated for 1 hour with two parts of water containing hydrochloric acid (usually 6—8 litres of concentrated acid per 1000 kilos. of maize), and then introduced into the first of two cookers, in which the pressure is raised to 60 lb. per sq. in. in 15—20 mins. and maintained for 15—30 mins. whilst a small quantity of steam is allowed to blow off in order to keep the mash in agitation. From the first cooker the material is blown into a second similar one the inlet to which is somewhat constricted so as to cause disintegration of the solid particles by sudden expansion (cp. Boidin, Eng. Pat. 19,633 of 1907, this J., 1908, 586). The pressure in the second cooker is kept at 30 lb. per sq. in. for 20—30 mins. and then the mash is blown into the fermentation vat. This is a vertical, air-tight cylinder with dome-shaped ends. The usual capacity is 1000 hl. (22,000 galls.) corresponding to a mash of 20—25 tons of maize. The contents are cooled to 40° C. by running water over the outside of the vessel (10—12 hours) and a current of sterilised air is passed upwards through the mash all the time. A pure spore culture of the mould, grown on moistened rice, is then introduced, rigorous precautions being taken to avoid infection of the mash with foreign organisms. During the first 21 hours, the temperature falls to 36·5° C., the sp. gr. of the filtered mash does not change, and no sugar is formed. After a further interval of 8 hours, a pure culture of the yeast is introduced; if added at an earlier stage it hampers the development of the mould. Vigorous fermentation sets in after 24 hours and the air current can be stopped. Fifty-three hours after inoculation with the mould, the quantity of sugar present is at its maximum, about 11·4 per cent., and afterwards it falls rapidly, and the process is complete within 4 days from inoculation. The final gravity of the filtered mash is about 1,000, the (apparent) reducing sugar is 0·3 per cent., the acidity 0·6 grm. per litre, and the mash gives no blue colouration with iodine. It is possible to work more quickly by saccharifying by means of a "bub" of the mould, 1/10 of the volume of the total mash, and made in a similar but smaller air-tight vessel. When manioc and potatoes are employed, malt is used instead of hydrochloric acid, to assist liquefaction of the starch. Potatoes are first ground to a fine mass, warmed to 65° C., mixed with crushed malt and water, stirred and warmed to 70°—75° C. for 15 mins., and then transferred to the cooker. Powdered manioc, mixed with 3 parts of water, is similarly treated with malt. No saccharification should take place, because the sugar would be caramelised in the cooker. The yield of alcohol obtained by the amylo-process is considerably higher than by other methods, for no dextrins are left unfermented and the fermentation is pure. The alcohol produced contains less foreshots and tailings and much less fusel oil than that obtained by non-aseptic fermentation. After the distillation of the fermented mash, the residue is filtered hot and the draff pressed and dried; the pressed cakes contain 20 per cent. of oil which is extracted with petroleum spirit and the dried residue is sold as cattle food. A sample of this residue contained water 8·53, oil 2·96, albuminoids (N × 6·25) 47·5, cellulose 8·27, extractive bodies 30·44 and salts 2·30 per cent. The amylo process is particularly suited for use in hot climates. Its use in this country is at present prohibited by the Excise Authorities. —J. H. L.

Beer; Rate of fermentation of priming solutions when added to ——. J. L. Baker and H. F. E. Hulton. J. Inst. Brew., 1914, 20, 241—247.

PRIMING may have two distinct objects, *viz.*, to impart sweetness and palate-fulness to running beers, and to induce and augment rapid conditioning. The materials most frequently used are cane sugar (candy), invert sugar, and dextrinous syrups prepared by the action of acids on starch. The effect of priming on running beers is more or less transitory, for the added sugar really brings about a continuance of the primary fermentation over a period which depends on a number of factors including treatment of the beer in the cellar. The authors' experiments indicate that cane sugar primings, added in the customary amounts, are completely inverted within 24 hours, and, contrary to the generally accepted view, are fermented at substantially the same rate as invert sugar primings. If beer in barrels is well mixed with priming solution, and the barrels are then shived up, rolled well and left for some time (*e.g.*, 16 hours) before the shives are cut out, about 40—75 per cent. of the added sugar is fermented within seven days; but if, after the priming has been well mixed in, the barrels are not shived up or rolled, practically no fermentation occurs for the first 2 or 3 days, and the amount of sugar fermented at the end of five days is small, *e.g.*, 9 per cent. of that added. —J. H. L.

Colloids in beers; Determination of ——. R. Marc. Kolloid-Zeits., 1914, 14, 181—186.

THE method described (see page 564) for the determination of colloids in effluents, may also be applied to the examination of beers, the sample being diluted with 10 times its quantity of water and 20 c.c. shaken with 10 grms. of finely powdered barium sulphate. The difference between the refraction before and after this treatment as ascertained in a Zeiss interferometer is a measure of the colloid content. Pale beers were found to contain a smaller quantity of colloids than dark beers, but when referred to the total dry solids of the beer, the colloid content was fairly constant at about 7·2 per cent. Of the colloids present in beer, starch and albumin are adsorbed more readily than dextrin, and by using 10 c.c. of the diluted beer and only 1 grm. of barium sulphate, selective adsorption was effected, the colloid content indicated (referred to the total dry solids) ranging, in six different beers, from 2·55 to 4·6 per cent. By repeated treatment with a relatively small quantity of adsorbent, fractional adsorption of the colloidal constituents could be effected and the results would give some indications of the character of the colloids present in a given sample of beer.—A. S.

Yeast; Beer ——, *a valuable fodder.* P. Dönhoff. Z. Spiritusind., 1914, 37, 263—269.

BY boiling pressed beer yeast for a few hours in a steam-heated, double-bottomed copper, a liquid and perfectly stable product is obtained which forms a valuable adjunct to swine fodder. The price at which the product can be sold (M. 4 per 100 kilos., or 2s. per cwt.) appears to render the process practicable even in small breweries.—L. E.

Grape must; Nitrogenous matter of ——. R. Marcille. Comptes rend., 1914, 158, 1199—1201. (See this J., 1913, 547.)

THE fermentation of musts that have been freed from volatile nitrogenous matter is not always abnormally slow. The volatile nitrogen always disappears almost completely during fermentation, and the yeast often utilises a considerable proportion of the organic nitrogen, a proportion which is much diminished by addition of ammonia to the must.

The ripening of the grapes is accompanied by a decrease of the volatile and organic nitrogen in the must.—L. E.

Aspergillus niger (Sterigmatocystis nigra V. Tgh.); Value of zinc for the growth of —— in deep media. M. Javillier. Comptes rend., 1914, **158**, 1216—1219. (See this J., 1912, 247, 912.)

Lepierre's statement that zinc does not accelerate the growth of *Aspergillus niger* in media of such depth that the ratio, volume of liquid : free surface, exceeds 2, is incorrect. The catalytic action is as well marked in deep as in shallow media.—L. E.

Determination of sulphur in honey and other materials containing much sugar. Nottbohm and Weinhausen. *See* XVII.

Patents.

Alcoholic beverages; Method of, and apparatus for treating and bottling beer, cider, sparkling wines, and other ——. D. E. Robbins, Sidley, Sussex. Eng. Pat. 8420, April 9, 1913.

The liquor, immediately before chilling and bottling, is allowed to undergo "bottle fermentation" in a large chamber which can be hermetically closed. It is withdrawn through outlet pipes of small diameter leading from the floor of the chamber. To prevent solid matter deposited during the fermentation from passing into the outlet pipes, a tray is supported a little above the floor of the chamber and over the outlet pipes, and a flange or a raised portion is provided on the floor of the chamber, around the outlet pipes, and within the area covered by the tray, the outlet pipes being connected with this raised portion.—L. E.

Brewing apparatus. C. B. Davis, New York. U.S. Pat. 1,094,059, April 21, 1914.

An apparatus for use in the brewing industry for separating liquids from solids, comprises a sieve and a number of hinged plates which can be moved into contact with the underside of the sieve so as to seal the perforations.—L. E.

Mash-filter for the separation of beer wort from grains. C. Rath. Ger. Pat. 271,200, Sept. 10, 1912.

The mash-filter consists of a series of closed chambers separated from one another only by filter-cloths and assembled in a closed casing in the manner of a filter-press. The mash enters the filter-chambers from a common inlet pipe and the wort passes through the filter-cloths into the adjacent chambers and flows away through passages provided for the purpose. Water is then introduced into the empty chambers on one side of the filter-chambers, and percolates through the press-cake into the chambers on the opposite side, whence it flows away to a receptacle.—A. S.

Vinegar; Apparatus for the manufacture of ——. A. Menegault, Arcueel, France. Eng. Pat. 27,260, Nov 26, 1913.

The acetifying vats are barrel-shaped, and a hoop on the bulge of each vat has 4 spiral grooves in which an endless rope makes 3 turns, the rope passing round each vat in succession. A drum, mounted on a shaft operated by an electric motor, and having oppositely directed spiral grooves at the ends, winds the rope. In each vat is a mercury thermometer: when the temperature rises, say to 37° C., the mercury closes the electric circuit, the motor is started, and the vats rotate; or rotation at definite intervals may be insured by an electric clock provided, at various points, with tappets which make contact with the hand and close the circuit.—L. E.

Producing fermentable sugars [from sawdust]. Eng. Pat. 14,938. *See* XVII.

Process for treating potatoes. Eng. Pat. 17,614. *See* XIXa.

XIXa.—FOODS.

Flour; Decrease of the quantity of gluten in ——. J. A. F. Balland. Comptes rend., 1914, **158**, 1103—1106.

In the period 1869 to 1880, the average quantity of moist gluten yielded by flours was 29·1 per cent. (or 9·7 per cent. of dry gluten), whilst for the period 1905 to 1914, the average was 24·7 per cent. The decrease does not appear to be due solely to degeneration of the wheat caused by intensive cultivation, but more probably to alterations in the milling processes and to the treatment (bleaching, moistening, etc.) to which the flour is subjected subsequently. —W. P. S.

Lard; Detection of beef and mutton fats in —— by Bömer's method. H. Sprinkmeyer and A. Diedrichs. Z. Unters. Nahr. Genussm., 1914, **27**, 571—581.

Application of Bömer's method (this J., 1914, 33, 323) to numerous samples of genuine lard, beef and mutton fats, and mixtures of the same, yielded results showing that the method is capable of detecting the presence of 10 per cent., and in many cases 5 per cent., of beef or mutton fat in lard. Lards rendered by the authors yielded a difference value of 4·4° to 7·4° (*i.e.*, the difference between the m.pts. of the least soluble glycerides and those of the corresponding fatty acids), whilst the value Mg+2d (m.pt. of the glyceride+twice the difference value) varied from 73·1 to 76·5. In the case of beef and mutton fats the difference value lay between 0·8 and 1·2 and the value Mg+2d between 65·2 and 67·3. With mixtures containing from 5 to 10 per cent. of beef fat the value Mg+2d was always below 72 and in the greater number of cases below 70. The presence of hydrogenated (hardened) fats in lard affects the value Mg+2d to about the same extent as does the presence of beef fat.—W. P. S.

Alum in foods; Use of ——. Report of Remsen Board. Oil, Paint, and Drug Rep., May 4, 1914. [T.R.]

The United States Department of Agriculture has issued a bulletin announcement of the final decision by the Remsen Referee Board on the general subject of alum in foods. The conclusions of the Board are summed up as follows:—

Aluminium compounds when used in the form of baking powders in foods have not been found to affect injuriously the nutritive value of such foods, nor in small quantities, have they been found injurious to health. The same holds true for the amount of aluminium which may be included in the ordinary consumption of aluminium baking powders furnishing up to 150 mgrms. of aluminium daily. Aluminium compounds when added to foods, in the form of baking powders, in large quantities, up to 200 mgrms. or more per day, may provoke mild catharsis and in very large quantities usually provoke catharsis, due to the sodium sulphate which results from the reaction. The aluminium itself has not been found injurious to health, beyond the production of occasional colic when very large amounts have been ingested. When mixed or packed with a food, the quality or strength of the food has not been found to be thereby reduced, lowered or injuriously affected.

Beer yeast, a valuable fodder. Dönhoff. *See* XVIII.

Patents.

Potatoes; Process for treating ——. E. Enders, Breslau, Germany. Eng. Pat. 17,614, July 31, 1913.

The potatoes, which are first peeled if the product is for human consumption, are cut up or mashed to pulp, treated with a small quantity of water if necessary, and freed from most of the juice by pressure or in any other suitable manner. The residue is boiled or steamed with or without addition of water, and finally dried at 80°—110° C. The juice is saccharified, fermented and distilled, alcohol and a liquid cattle food being obtained.—L. E.

Food composition for stock. A. D. Little, Boston, Mass., Assignor to Standard Alcohol Co., New York. U.S. Pat. 1,092,221, April 7, 1914.

Substances containing cellulose are treated with a hydrolysing agent containing chlorine under conditions suitable to the formation of sugars; the hydrolysing agent is then converted into sodium chloride and excess of moisture is removed from the mass.—W. P. S.

Milk and other liquids; Treating—. G. M. S. Tait, Washington, D.C. U.S. Pat. 1,094,380, April 21, 1914.

The bottles, in which the milk is to be pasteurised, are first washed and scalded, and, whilst still above 130° F. (54·4° C.), the unpasteurised milk, preheated to about 130° to 150° F. (54·4°—67·8° C.), is added, the heating being continued at about 130° to 140° F. (54·4°—60° C.) to complete the pasteurisation.—B. N.

Milk; Artificial —— and process and apparatus for making the same. G. Rigler, Kolozsvár, Hungary. Eng. Pat. 18,382, Aug. 13, 1913. Under Int. Conv., Oct. 29, 1912.

See Fr. Pat. 461,131 of 1913 this J., 1914, 215.—T. F. B.

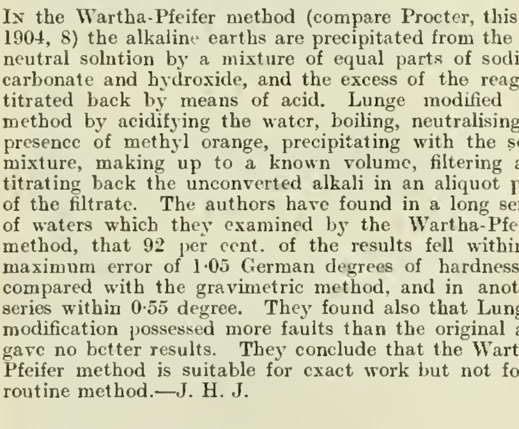
XIXb.—WATER PURIFICATION; SANITATION.

Hardness of waters; Determination of —— by the methods of Wartha-Pfeifer and Blacher. J. Zink and F. Hollandt. Z. angew. Chem., 1914, **27**, 235—237.

In the Wartha-Pfeifer method (compare Procter, this J., 1904, 8) the alkaline earths are precipitated from the hot neutral solution by a mixture of equal parts of sodium carbonate and hydroxide, and the excess of the reagent titrated back by means of acid. Lunge modified the method by acidifying the water, boiling, neutralising in presence of methyl orange, precipitating with the soda mixture, making up to a known volume, filtering and titrating back the unconverted alkali in an aliquot part of the filtrate. The authors have found in a long series of waters which they examined by the Wartha-Pfeifer method, that 92 per cent. of the results fell within a maximum error of 1·05 German degrees of hardness as compared with the gravimetric method, and in another series within 0·55 degree. They found also that Lunge's modification possessed more faults than the original and gave no better results. They conclude that the Wartha-Pfeifer method is suitable for exact work but not for a routine method.—J. H. J.

Nitrification; Experiments on the rate of ——. R. M. Beesley. Chem. Soc. Trans., 1914, **105**, 1014—1024.

Solutions containing 100 mgrms. of combined nitrogen in 500 c.c., together with the necessary inorganic salts were sterilised and then inoculated with 1 c.c. of an infusion of hydrolytic and nitrifying organisms from a secondary contact bed for sewage treatment. The solutions were protected from contamination, frequently shaken and aerated, and periodic determinations of "ammoniacal," "nitrous" and "nitric" nitrogen made. Trithiourea and aniline sulphate were not nitrified, the latter becoming converted into ammonia. Asparagine was apparently immediately hydrolysed chemically, half of its nitrogen being liberated as ammonia. From this point, however, as in the other substances examined, urea, uric acid, glycine, methylamine sulphate, acetamide, ammonium oxalate and ammonium sulphate, its nitrification pursued the normal course. All nitrified at about the same rate, the curve being of the type shown in the figure. Not more than 95 per cent. of the original nitrogen was recovered as nitrate in any case, the loss being due to aeration and interaction between ammonia and nitrous acid. In the cases of ammonium oxalate and ammonium sulphate, where all the nitrogen should have been found as ammoniacal, nitrous or nitric, a remarkable temporary deficiency (as much as 40 per cent.) was found in the middle of the period, suggesting that there are other stages besides the ones named in the nitrification of ammonium compounds. —W. H. P.



Colloids in effluents; Simple method for the determination of ——, and the use of the liquid-interferometer in the examination of water. R. Marc and K. Sack. Kolloidchem. Beihefte, 1914, **5**, 375—410.

An account of further work on the application of the interferometer to the examination of waters and effluents (see this J., 1912, 559). To determine colloids in effluents, 20 grms. of the latter are shaken for half an hour with 10 grms. of an insoluble substance, preferably carefully purified barium sulphate, in the form of a fine crystalline powder, and, after separating the insoluble matter, the clear solution and the original effluent are examined in the interferometer: the decrease in the refraction is proportional to the quantity of colloids in the effluent. By determining the permanganate consumption (due to the organic colloids) before and after shaking with barium sulphate, indications as to the relative quantities of organic and inorganic colloids can be obtained. Experiments of this kind showed that in most purification processes, especially in filtration through soil, the organic colloids are rapidly removed, whilst the inorganic colloids remain unaffected.

The determination of the refraction by means of the interferometer may also be used in place of, or as an adjunct to, the determination of the total soluble matter in water analysis. For waters of similar kind and origin the quotient of the refraction and dry residue is practically constant: with waters of different kinds this quotient is higher the lower the quality of the water.—A. S.

Water and its purification for tannery purposes. Corin. *See* XV.

Colorimetric method for detecting and determining nitrates and nitrites. Letts and Rea. *See* XXIII.

Patents.

Water; Means for softening ——. G. Buchner, München, Germany. Eng. Pat. 22,647, Oct. 7, 1913.

The water is treated with a mixture of disodium phosphate and borax, to which may be added alkalis, alkaline earths or their carbonates or phosphates, magnesium or aluminium carbonates or phosphates, or organic acids.—W. P. S.

Water; Sterilisation of —— by means of bromine. M. Riegel. Ger. Pat. 272,271, April 30, 1913.

The water is treated with hydrochloric acid and with a solution of bromine in potassium bromide, and free acid and bromine are subsequently removed by addition of the calculated quantity of sodium sulphide, sodium carbonate or other alkaline substance.—A. S.

Sewage sludge and the like; Apparatus for drying ——. J. Bromet, F. Thorman, and H. C. Wood, Tadcaster, Yorks. Eng. Pat. 7822, April 3, 1913.

A slightly inclined, rotating cylinder is heated externally by gases from a furnace and is provided internally with scrapers, pegs, teeth and lifting plates so that the sludge, whilst passing through the cylinder, is brought into intimate contact with a current of hot air which is circulated continuously through the cylinder and a heater until it is saturated with moisture, when it is passed into the combustion chamber of the furnace. Two similar drying cylinders may be used in series.—W. P. S.

Sewage and other waste liquids; Apparatus for the treatment of ——. T. K. Irwin, London. Eng. Pat. 20,816, Sept. 15, 1913.

The sewage is treated with precipitants or neutralising agents, then delivered into a tank from the top of which it overflows and passes through a screen on to a filter. The liquid passing from the filter is aerated by means of a centrifugal machine and then passes through a screen on to a second filter. While in the first tank the liquid may be heated and the waste gases from the furnace supplying the heat may be employed for drying the sludge removed from the tanks and screens.—W. P. S.

Waste liquids; Method of separating foreign matter from ——. W. Loebel, Leipzig, Germany. Eng. Pat. 19,596, Aug. 29, 1913.

The liquid is allowed to fall from a pipe on to a flat plate, or sprayed or injected against vertical plates, or made to flow down a series of steps in order to separate air bubbles from the suspended particles, and is then led into a settling tank.—W. P. S.

Tanks for separating combustible liquids and solid matters from waste water. A. Kützer, Leipzig-Stünz, Germany. Eng. Pat. 27,977, Dec. 4, 1913.

A tank for separating oil, petrol, etc., from waste water, has a discharge pipe for the aqueous portion of the waste water, this pipe extending outside the tank from the bottom to a point near the top. Baffle-plates in the tank direct the lighter portions, such as oil, petrol, etc., towards the centre of the top of the tank where they overflow into a vertical central pipe; the latter passes through the bottom of the tank and its upper edge is just above the level of the water outlet. A bell, extending over nearly the whole width of the tank, is placed over the central pipe, and the waste water is admitted to the tank over the upper surface of this bell. In a modified form of the tank, a receptacle for the oil, etc., is substituted for the central pipe.—W. P. S.

Disinfectant. F. Hoffmann-La Roche und Co. Ger. Pat. 271,732, Nov. 15, 1910. Addition to Ger. Pat. 263,332 (see this J., 1913, 1028).

The disinfectants consist of mixtures of soaps and halogen-ethylenes: the halogen compounds may be dissolved in soap solutions in presence of acetone, alcohol, or suitable salts, or the halogen-ethylenes may be mixed with solid or semi-solid soaps in presence of similar substances to render the product soluble in water.—T. F. B.

Water; Process and apparatus for purifying natural —— *by means of sunlight and artificial light.* A. Koch, Hannover-List, Germany. Eng. Pat. 9486, April 22, 1913. Under Int. Conv., April 23, 1912.

See Fr. Pat. 456,953 of 1913; this J., 1913, 1083.—T. F. B.

Water; Process and apparatus for purifying ——. Maschinen- und Waggonbau-Fabriks Akt.-Ges., vorm. H. D. Schmid, and F. R. von Suess, Vienna. Eng. Pat. 25,715, Nov. 10, 1913. Under Int. Conv., Nov. 11, 1912.

See Fr. Pat. 464,670 of 1913; this J., 1914, 500.—T. F. B

Sewage and refuse separator. B. Kaibel, Darmstadt, Germany. U.S. Pat. 1,093,994, April 21, 1914.

See Fr. Pat. 456,425 of 1913; this J., 1913, 1028.—T. F. B.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Peru balsam. K. Dieterich. Ber. deuts. Pharm. Ges., 1914, **24**, 225—232. (See also this J., 1914, 159.)

When distilled in a current of steam, Peru balsam yielded about 5 per cent. of a thick yellowish oil having an odour like that of the original material (see following abstract). Volatile substances added as adulterants can be detected in this way. A sample of balsam about 50 years old showed normal values, though variations in some of the colour reactions were noticed. Irregularities in the preparation of a genuine balsam may also cause abnormal colour reactions in the nitric acid and zone tests.—F. Shdn.

Peru balsam; Essential oil obtained by the steam distillation of ——. A. W. Sortell. Ber. deuts. Pharm. Ges., 1914, **24**, 233—234.

The oil (see preceding abstract) had the sp. gr. 1·0869 at 17° C., saponification value 245·7, and $[\alpha]_D = +1\cdot876°$. After saponifying the oil had sp. gr. 1·002 and $\alpha_D = +4°$ at 20° C. Benzyl alcohol and peruviol were found to be present in the saponified oil, the greater portion of which distilled at 98° C. at 16 mm. Benzoic and cinnamic acids were produced by the hydrolysis.—F. Shdn.

Rose oil; Composition and adulteration of ——. N. Petkow. Z. öffentl. Chem., 1914, **20**, 149—153.

Owing to the use of artificial substances such as "steareoptene" and "ceril" for adulterating rose oil their importation into Bulgaria has been forbidden. The characters of genuine rose oil (six samples), a concrete prepared by extracting the flowers with light petroleum, and specimens of artificial stearoptene and ceril are shown in the following table:—

	Rose oil.	Concrete.	Stearoptene.	Ceril.
M. pt.	—	—	38·5° C.	—
Saponif. value	9·4—12·4	38·5	5·6	10·3
Acid value	1·1— 1·9	7·1	2·0	1·2
Ester value	8·3—10·9	31·4	3·5	9·1
Refractometer reading	43·9—51·2 at 25° C.	62 at 60° C.	13 at 50° C.	43 at 40° C.
Iodine value	170·8—189·1	51·3	4·6	174·4
Optical rotation	—1·04° to —2·9°	—	—	—
Sp. gr. at 25° C.	0·8535—0·861	—	—	—

The corresponding figures for a number of adulterated oils are also given.—F. Shdn.

Carbon tetrachloride; Use of—for the extraction and determination of the active principles of drugs and medicinal plants. G. Gori. Boll. Chim. Farm., 1913, **52**, 891—895. Chem. Zentr., 1914, **1**, 1377—1378.

At 20° C. 100 parts of carbon tetrachloride dissolve: caffeine 0·258 part, quinine 0·544, strychnine 0·220, brucine 2·030, cocaine 31·942, atropine 1·760, morphine 0·025, codeine 2·940, papaverine 0·518, narcotine 1·040, and narceine 0·002 part: theobromine is insoluble. In the determination of caffeine in kola nut powder and green coffee, carbon tetrachloride gives results agreeing with those obtained by use of chloroform. In the analysis of tho fluid extract of kola, the caffeine may first be determined by extraction with carbon tetrachloride, and then the theobromine by extracting the residue with chloroform.—A. S.

Essential oils; Relative permanence of ——. J. C. Umney. Perfum. and Essent. Oil Rec., 1914, **5**, 99—100.

Definite quantities of essential oils were put on blotting paper, which was then exposed to a free current of air at about 15° C. For permanence of odour, the following oils stand out in the order given: patchouli, sandalwood, cinnamon leaf, cassia, Java citronella, origanum, thyme, neroli. With certain oils, for instance, anise, almond and ylang ylang oils, the character of the odour altered on exposure.—F. Shdn.

Essential oils; Determination of volatile acids in ——. J. C. Umney. Perfum. and Essent. Oil Rec., 1914, **5**, 116—118.

The apparatus consists of a 3-litre Jena glass flask for generating steam, connected with a long-necked 150 c.c. Jena flask, an efficient splash head being fitted to the latter which leads to a vertical Davies' condenser delivering the distillate into a 500 c.c. conical flask. About 2 grms. of the oil are weighed into the small long-necked flask, 15 c.c. of neutralised alcohol and a little phenolphthalein are added, the whole heated just to boiling on the steam bath and the acid number ascertained by titrating with *N*/10 alcoholic potassium hydroxide. 25 c.c. of *N*/2 alcoholic potassium hydroxide (best prepared from 90—96 per cent. alcohol distilled over potash) are then added, the whole boiled under a reflux apparatus for an hour, the excess of alkali neutralised with *N*/2 sulphuric acid after the addition of 40 c.c. of water free from carbon dioxide, a few drops of *N*/2 alcoholic potassium hydroxide added, the liquid evaporated on the water bath, and 10 c.c. of dilute phosphoric acid (3·5 c.c. of 88 per cent. acid with 100 c.c. of water) added. The distillation apparatus should be treated to a preliminary boiling of at least half an hour's duration, and steam allowed to blow through the connecting tubes and condenser to remove carbon dioxide. The small flask is then connected up and heated by a small flame whilst the water in the large flask is kept boiling as rapidly as possible. The distillation is continued till 250 c.c. have been collected, which should take about 30 minutes. The free acid is determined in the distillate by means of *N*/10 sodium hydroxide, using phenolphthalein as indicator. Satisfactory results can also be obtained by using the method of Gladding for the estimation of acetic acid in calcium acetate (see this J., 1909, 467).—F. Shdn.

Essential oils; Constituents of ——. Separation and properties of the sesquiterpenes (gurjunenes) in East Indian copaiba oil; derivatives of the sesquiterpenes. F. W. Semmler and W. Jakubowicz. Ber., 1914, **47**, 1141—1153. (See also this J., 1914, 436.)

A crude gurjunene of sp. gr. 0·922 at 20° C., $n_D = 1·50737$, and $\alpha_D = -55°$ was oxidised by chromic acid dissolved in glacial acetic acid, the product washed with water and sodium carbonate solution and distilled. The fraction boiling between 118° and 150° C. at 10 mm. and with $\alpha_D = +10°$ was again oxidised in the same way and fractionated. The fraction boiling between 118° and 140° C. at 10 mm. was oxidised further with a cooled solution of permanganate in acetone. After again fractionating and distilling over sodium, pure tricyclogurjunene (cedrene type), $C_{15}H_{24}$, was obtained. This boiled at 120°—123° C. at 13 mm., had the sp. gr. 0·9348, $n_D = 1·50275$ and $\alpha_D = +74·5°$. The higher boiling fractions when treated with semicarbazide solution gave a semicarbazone of m.pt. 237° C. The ketone, $C_{15}H_{22}O$, obtained therefrom by decomposing with phthalic anhydride had the b.pt. 163°—166°C. at 10 mm., m.pt. 43° C., sp. gr. 1·017 at 20° C., $n_D = 1·52700$, $\alpha_D = +123°$ (see this J., 1910, 898). Reduction with sodium and alcohol gave gurjunene alcohol, $C_{15}H_{24}O$, m.pt. 104° C., b. pt. 155°—159°C., sp. gr. 1·001, $n_D = 1·51859$, $\alpha_D = +34°$. Tricyclodihydrogurjunene (cedrene type), $C_{15}H_{26}$, was obtained by reducing the sesquiterpene with hydrogen in the presence of platinum. It had the b. pt. 120° C. at 8 mm., sp. gr. 0·9258, $n_D = 1·49775$, $\alpha_D = -37·5°$. The tricyclogurjunene was also obtained from the semicarbazone of m. pt. 237° C. by heating with sodium ethoxide in alcohol to 160° C. This sesquiterpene gave no colouration when the solution in glacial acetic acid was treated with sodium nitrite solution and concentrated sulphuric acid (Turner's reaction). The original crude gurjunene contained a large proportion of tricyclene-gurjunene (α-gurjunene), which was separated after fractionation and had the characters: b. pt. 114°—116° C., sp. gr. 0·918 at 20° C., $n_D = 1·5010$, $\alpha_D = -95°$. This substance as well as the original crude sesquiterpene gave a violet colouration when tested by Turner's reaction. When oxidised by means of permanganate, an indifferent oxidation product was formed boiling between 165° and 180° C. at 12·5 mm. and with $\alpha_D = -69°$. The crude sesquiterpene became dextro-rotatory after heating to 290° C. and only combined with two atoms of hydrogen in the presence of platinum.
—F. Shdn.

Camphor dissolved in olive oil; Specific rotatory power of ——. H. Malosse. Bull. Soc. Chim., 1914, **15**, 358—359.

The values for the specific rotatory power of camphor when dissolved in olive oil at different concentrations are tabulated and shown in a curve-diagram. For solutions containing from 75 to 95 per cent. by weight of olive oil the results may be expressed by the following formulæ, where *c* represents grms. of camphor in 100 c.c. of solution, *p*=grms. of camphor and *q*=grms. of oil in 100 grms of, solution:—

$$[\alpha]^{15}_{D} = 57·9 - 0·53399c + 0·02834c^2 - 0·0005023cq^3$$
$$[\alpha]^{15}_{D} = 57·9 - 0·4894p + 0·023805p^2 - 0·0003867p^3$$
$$[\alpha]^{15}_{D} = 139·69 + 7·3294q - 0·092205q^2 + 0003867^3$$

—A. S.

Dibenzoylglucoxylose: a natural benzoyl derivative of a new disaccharide. F. B. Power and A. H. Salway. Chem. Soc. Trans., 1914, **105**, 1062—1069.

The bitter taste of the leaves and stems of the Australian shrub, *Daviesia latifolia*, R.Br., is due to the presence of considerable quantities of a crystalline dibenzoyl derivative, $C_{25}H_{28}O_{12}.H_2O$, of a new disaccharide $C_{11}H_{20}O_{10}$. The benzoyl compound melts at 147°—148°C., is sparingly soluble in cold water, ether and chloroform, but readily soluble in alcohol and hot water, from which prismatic needles containing one molecule of wate separate on cooling. It is lævorotatory ($[\alpha]_D = -106·7$ in methyl alcohol solutions), non-reducing, and yields penta-acetyl derivative melting at 203° C. The benzoy groups are eliminated by caustic alkalis in the cold, and th product, obtained by evaporating a methyl alcohol solutio *in vacuo*, forms an amorphous, horn-like solid, $C_{11}H_{2}O_{1}$ nearly colourless, which rapidly absorbs water from th air. This product is very soluble in water, moderatel soluble in alcohol, possesses a sweet taste, does n reduce Fehling's solution or yield an osazone, and it aqueous solutions are lævorotatory ($[\alpha]_D$=about −30 When hydrolysed with acids it yields dextrose and pentose, evidently xylose. The change in optical rotati ("inversion") which accompanies complete hydroly (by heating for 10 mins. at 80° C. with mineral acids

5 per cent. concentration) accords with the conclusion that the disaccharide is a glucoxylose, and the following formula is suggested :—

$$HO.CH_2{\cdot}CHOH{\cdot}CH(CHOH)_2CH{\cdot}O{\cdot}CH(CHOH)_2CH{\cdot}CH_2OH.$$

—I. H. L.

Grignard reagent ; Action of chromic chloride on the ——. G. M. Bennett and E. E. Turner. Chem. Soc. Trans., 1914, 105, 1057—1062.

Attempts to prepare organo-metallic derivatives of chromium by the action of anhydrous chromic chloride on Grignard reagents (organo-magnesium compounds) failed : instead, a reaction took place of the type :

$$2CrCl_3+2C_6H_5.MgBr= C_6H_5.C_6H_5+2CrCl_2+MgCl_2+MgBr_2 ;$$

and the method proved very satisfactory for the preparation of diarylhydrocarbons. Grignard reagents from bromobenzene, benzyl bromide, *a*-bromonaphthalene, and *p*-iodotoluene gave excellent yields of diphenyl, *s*-diphenylethane (dibenzyl), *aa*-dinaphthyl, and 4 : 4′-dimethyl diphenyl respectively. It was not found possible to obtain 2 : 2′-dimethyldiphenyl from *o*-iodo- or *o*-bromotoluene in this way, and only a very poor yield of di-isoamyl was obtained from isoamyl iodide.—A. S.

Hydroxylamine ; Detection and determination of ——. H. Schroeder. Chem. News, 1914, 109, 205.

Angelis' test (this J., 1895, 771) for hydroxylamine is modified thus :—The liquid to be tested is carefully neutralised with hydrochloric acid or sodium hydroxide, and 2 c.c. are shaken with 1 mgrm. of solid sodium nitroprusside and 1 c.c. of *N*/10 sodium hydroxide, and rapidly heated to 100° C. in a water-bath. In the presence of hydroxylamine, at a concentration of 0·01 per cent., a magenta colouration is developed. By diluting the liquid to 50 c.c. in a Nessler tube, the hydroxylamine may be estimated colorimetrically by comparison with a standard solution, or colour standards may be made for permanent use from a mixture of methyl orange and phenolphthalein. —J. F. B.

Light ; Supposed chemical changes by the action of ——. E. Sernagiotto and A. Baron Hoschek. Z. physiol. Chem., 1914, 90, 437—440.

The authors repeated some of the experiments of Inghilleri on photochemical synthesis (this J., 1911, 986 ; 1912, 793), but were unable to confirm his results. The amount of methyl alcohol formed by the interaction of formaldehyde and water was not appreciably increased by exposing the reaction mixture to sunlight. Only a trace, at most, of methyl formate was produced by the action of light on a mixture of formaldehyde solution and methyl alcohol. The " new " alkaloid obtained by Inghilleri by the action of light on a mixture of formaldehyde, ammonia and methyl alcohol, proved to be hexamethylenetetramine. A mixture of glycerol and oxalic acid, whether exposed to, or protected from light, yielded only a very small quantity of butyric acid, and, as a control experiment showed, this acid appears to be derived from the glycerol alone.—L. E.

Patents.

C-Allylsalicylic acid. L. Claisen, Godesberg, Germany, Assignor to Synthetic Products Co., New York. U.S. Pat. 1,094,123, April 21, 1914.

A C-allylsalicylic acid is claimed, in which the allyl group probably occupies the position adjacent to the hydroxyl group, and which crystallises in needles of m. pt. 96° C. : it is a valuable antipyretic (see Ger. Pat. 268,982 ; this J., 1914, 277).—T. F. B.

Isoprene ; Process of producing ——. L. P. Kyriakides and R. B. Earle, Assignors to Hood Rubber Co., Boston. U.S. Pats. 1,094,222 and 1,094,223, April 21, 1914.

(1.) Isoprene is obtained by passing the vapours of an isoamylene oxide over a dehydrating catalyst (*e.g.*, heated aluminium silicate), at less than atmospheric pressure ; the catalyst may be heated to between 400 and 600° C. (2.) The vapours of a methylbutane-diol, such as 1.3-dihydroxy-2-methylbutane, are passed over a heated dehydrating catalyst at a reduced pressure.—T. F. B.

1.3-*Diols ; Process for producing* ——. L. P. Kyriakides and R. B. Earle, Cambridge, Mass., Assignors to Hood Rubber Co. U.S. Pat. 1,094,224, April 21, 1914.

Ketone-alcohols are converted into 1.3-diols by electrolytic reduction in acid media, *e.g.*, in sulphuric acid solution using lead electrodes.—T. F. B.

Aldol ; Process of producing ——. R. B. Earle and L. P. Kyriakides, Cambridge, Mass., Assignors to Hood Rubber Co. U.S. Pat. 1,094,314, April 21, 1914.

Acetaldehyde, either in the form of vapour or liquid, is brought in contact with an alkaline condensing agent. For example, liquid acetaldehyde is brought in contact with dry slaked lime, the resulting liquid is removed, the acetaldehyde in the liquid is evaporated, and the process is repeated until a concentrated solution of aldol is obtained.—T. F. B.

1.3-*Glycols ; Process for producing* ——. R. B. Earle and L. P. Kyriakides, Cambridge, Mass, Assignor to Hood Rubber Co. U.S. Pats. 1,094,315 and 1,094,316, April 21, 1914.

(1.) Aldols are reduced electrolytically to 1.3-glycols in alkali carbonate (sodium bicarbonate) solution, using a mercury cathode, at a temperature below 20° C. A current density between 4 and 5 amps. per 100 sq. cm. of cathode surface, at 5 to 16 volts, may be used. (2.) The 1.3-glycols (β-glycols) are produced by reducing 1.3-ketone-alcohols electrolytically, at a mercury cathode, in sodium bicarbonate solution, below 20° C., using a current density of 3 to 6 amps. per 100 sq. cm. cathode surface at over 3 volts.—T. F. B.

Pharmaceutical or medicinal compound [a-bromo-isovaleryl-p-phenetidide] and process for producing the same. P. Bergell, Berlin-Wilmersdorf, Assignor to J. D. Riedel A.-G., Berlin-Britz, Germany. U.S. Pat. 1,094,296, April 21, 1914.

a-Bromo-isovaleryl bromide is added slowly, with stirring, to a solution of *p*-phenetidine in benzene, and the liquid is heated, filtered, and allowed to cool : a-bromo-isovaleryl-*p*-phenetidide is thus obtained, of m. pt. 151° C., sparingly soluble in water, easily soluble in alcohol, ether, and benzene, and slowly decomposed by alcoholic alkali solutions. It possesses soporific and strong antineuralgic properties.—T. F. B.

Trehalose and a vegetable acid ; Process for obtaining ——. R. Worms. Ger. Pat. 271,789, Nov. 16, 1912.

Selaginellacenes are extracted with a solvent (*e.g.*, aqueous alcohol), and the extract, which is free from chlorophyll and resin, is treated for the recovery of the carbohydrate and acid. For example, a substance such as alcohol may be added, in which the trehalose is sparingly soluble. The solution contains a new acid, *selaginellic acid*, which is distinguished by the fact that it forms golden yellow solutions with alkalis. It can be separated from the extract by means of its lead salt, or by extraction with a solvent which is immiscible with water.—T. F. B.

Dihydroxybenzene-arsinic acid ; Process for preparing a ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,892, Nov. 12, 1912.

The treatment of 4-hydroxybenzene-1-arsinic acid with potassium persulphate in aqueous-alkali solution, results in the introduction of a second hydroxyl group into the benzene nucleus, with the formation of a dihydroxybenzene-arsinic acid.—T. F. B.

3.3′-Diamino-4.4′-dihydroxyarsenobenzene ; Process for preparing neutral derivatives of —— soluble in water. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,893, Feb. 1, 1913. Addition to Ger. Pat. 245,756.

3.3′-Dinitro-4.4′-dihydroxyarsenobenzene is used in place of the corresponding diamino compound or the 3-nitro- or 3-amino-4-hydroxybenzene-1-arsinic acid in the processes described in the principal patent or in Ger. Pats. 260,235, 263,460, and 264,014 (see this J., 1912, 604 ; 1913, 960, 1039).—T. F. B.

3.3′-Diamino-4.4′-dihydroxyarsenobenzene ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,894, Feb. 1, 1913. Addition to Ger. Pat. 206,456.

3-Nitro-4-hydroxybenzene-1-arsinic acid, or 3.3′-dinitro-4.4′-dihydroxyarsenobenzene or 3-nitro-4-hydroxybenzene-arsenoxide is reduced by means of hypophosphorous acid or of phosphorous acid and potassium iodide or hydriodic acid, preferably in presence of acetic acid (see also Ger. Pats. 269,886 and 269,887 ; this J., 1914, 375).—T. F. B.

Organic arsenic compounds ; Process for preparing easily soluble ——. H. Bart. Ger. Pat. 272,035, May 14, 1912.

Derivatives of arsenobenzene or of phenylarsine which contain an amino group, alone or in addition to other substituents, are treated with aldehydesulphonic acids in equimolecular proportions. The alkali salts of the products are easily soluble in water. They are applicable to medicine.—T. F. B.

Aromatic mercury compounds ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 272,289, Jan. 30, 1913.

Aromatic arsenic compounds which contain tervalent arsenic, are treated with mercuric oxide or a mercury salt. In this reaction, which may be carried out in acid, neutral, or alkaline solution, the mercury replaces the arsenic, which is split off in the form of arsenious acid, and the mercury becomes attached to the benzene nucleus, producing compounds of the type, Ar.Hg.X, or Ar.Hg.Ar. —T. F. B.

Acid esters from esters lower in hydrogen ; Process for preparing ——. K. H. Wimmer. Ger. Pat. 271,985, July 6, 1912.

Glycerides or other esters of unsaturated fatty acids are hydrogenated by means of hydrogen or gaseous mixtures containing hydrogen in presence of a catalyst and a substance which combines with water. The hydrolysis of the ester is avoided by this process.—T. F. B.

Reduction of organic compounds by means of hydrogen in presence of palladium ; Process for the ——. Naaml. Vennootsch. Ant. Jurgens' Vereenigde Fabrieken. Ger. Pat. 272,340, March 26, 1912.

Palladium in a coherent form, *e.g.*, in filings or in coherent coatings on other substances, is used as catalyst in the reduction of organic compounds by hydrogen. The use of the metal in this form has the advantage over using the metal in powder that it is easily separated from the product of the reaction, and it can be regenerated by simple ignition.—T. F. B.

Salts of lower fatty acids ; Process for preparing a mixture of ——. J. Ederer. Ger. Pat. 272,036, April 23, 1913.

Comminuted wood is extracted with lime water or other alkaline solution in a diffusion battery at the ordinary temperature on with gentle heat, and at the ordinary pressure, until the solution is saturated with the salts of the lower fatty acids ; the liquid is then evaporated. The yields of fatty acids obtainable by this method vary between 1 to 2 per cent. for pine wood and 5 to 6 per cent. for beech, calculated on the air-dried wood. The acids consist mainly of acetic acid with 1 to 3 per cent. of formic acid and a trace of butyric acid.—T. F. B.

Lecithin preparations obtained by treating egg-yolk with acetone ; Process for purifying the ——. G. Fendler. Ger. Pat. 272,057, Feb. 15, 1913.

The lecithalbumin preparations, obtained by extracting egg-yolk with acetone, are thoroughly moistened with water or with an aqueous liquid such as milk, and the mass is dried at the ordinary temperature or by heating. This process removes the unpleasant taste due to the solvent, and is preferable to the purification of the product by washing with water, which is liable to remove certain valuable salts and albuminous substances.—T. F. B.

Agar-agar preparation giving clear solutions ; Process for preparing an ——. E. Merck. Ger. Pat. 272,145, June 22, 1913.

Commercial agar-agar is dissolved in hot water, filtered, and congealed by freezing ; after it has become liquid again it is separated from the aqueous liquid and washed with cold water until the washings contain no residue, whereupon it is dried. The final washing process may be replaced by repeated freezings and thawings, the aqueous liquid being separated after thawing and sufficient water added to make up the original volume. This treament removes the portion of the crude agar which is soluble in cold water and which does not set.—T. F. B.

Polymethylene-bis-imino acids and their salts ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 272,290, Nov. 13, 1912.

Polymethylenediamines or their homologues are treated with cyanides and aldehydes or ketones, and the resulting dinitriles are converted into the corresponding acids by the usual methods ; the acids may then be converted into salts, particularly copper salts. The copper salts are very easily assimilated, and may be used for the treatment of infectious diseases, especially tuberculosis.—T. F. B.

Cantharidyl-ethylenediamine ; Process for preparing salt-like double compounds from ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 272,291, March 21, 1913. Addition to Ger. Pat. 269,661 (see this J., 1914, 375).

The condensation product from cantharidine and ethylenediamine is treated with heavy metal salts other than gold salts. The products are suitable for use in medicine. —T. F. B.

Compound containing silicon ; Process for preparing a ——. H. Weyland. Ger. Pat. 272,338, Feb. 15, 1913.

Urea is heated with silicon tetrachloride. The product contains silicon and has the properties of a weak acid, forming a soluble sodium salt, from which the free compound is obtained by treatment with carbon dioxide. It may be used for medicinal purposes.—T. F. B.

Soluble colloidal substances ; Process for preparing ——. L. Sarason. Ger. Pat. 272,386, Sept. 2, 1913.

Solutions of nucleinic acid are used as colloidisers in the preparation of hydrosols by the known methods. The products are very stable.—T. F. B.

Aluminium acetate compounds soluble in water ; Process for preparing ——. Kalle und Co. A.-G. Ger. Pat. 272,516, July 7, 1912.

Hexamethylenetetramine is added to a solution o aluminium acetate, and preferably also a substance whic increases the solubility of the acetate in water, such as glycerin, mannitol, citric acid, lactic acid, or tartaric acid. The resulting solution may be evaporated to dryness, giving products which dissolve in water. The new double compounds may be used for medicinal purposes.—T. F. B.

Lactide ; Manufacture of ——. G. B Ellis, London. From Chem. Werke vorm. Dr. H. Byk, Berlin. Eng. Pat. 8771, April 14, 1913.

See Fr. Pat. 456,824 of 1913 ; this J., 1913, 1086.—T. F. B.

Ethers of monohydric alcohols and polyhydric substitution products of aromatic hydrocarbons ; Process for the production of ——. C. Torley, Brussels, and O. Matter, Troisdorf, Germany. Eng. Pat. 9451, April 22, 1913.

See Fr. Pat. 457,843 of 1913 ; this J., 1913, 1003.—T. F. B.

Salicylic acid compound : Process for the manufacture of a ——. H. Weitz, Berlin-Wilmersdorf, Germany. Eng. Pat. 9715, April 25, 1913. Under Int. Conv., May 24, 1912.

See Ger. Pat. 262,328 of 1912 ; this J., 1913, 925.—T. F. B.

Acyl sulphuric acids and the alkali and earth alkali metal salts of acyl sulphuric acids ; Process for the manufacture of ——. E. C. R. Marks, London. From Naamlooze Vennootschap Fabriek van Chemische Produkten, Schiedam, Holland. Eng. Pat. 12,130, May 24, 1913.

See Fr. Pat. 461,539 of 1913 ; this J., 1914, 219.—T. F. B.

Isoprene and erythrene ; Manufacture of ——. P. A. Newton, London From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 13,321, June 9, 1913. Addition to Eng. Pat. 19,919, Sept. 7, 1911.

See Addition of June 10, 1913, to Fr. Pat. 439,381 of 1912 ; this J., 1913, 1129.—T. F. B.

Bismethylaminotetraminoarsenobenzene ; Manufacture of aqueous solutions of ——. C. F. Boehringer und Söhne, Mannheim-Waldhof, Germany. Eng. Pat. 1667, Jan. 21, 1914. Under Int. Conv., Jan. 23, 1913.

See Ger. Pat. 269,660 of 1913 ; this J., 1914, 374.—T. F. B.

Turpentine or turpentine oil ; Depolymerisation of ——. A. Heinemann, London. U.S. Pat. 1,092,838, April 14, 1914.

See Eng. Pat. 1953 of 1912 ; this J., 1913, 252.—T. F. B.

Pharmaceutical compounds [alkoxymethyl esters of cresotinic acids]. J. Callsen, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,094,119, April 21, 1914.

See Eng. Pat. 16,387 of 1913 ; this J., 1913, 1030.—T. F. B.

Keto compounds from ketones and alkylaminomethanes or tetra-alkyldiaminomethanes : Process of producing ——. G. Merling and O. Chrzescinski, Elberfeld, and H. Köhler, Leverkusen, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pats. 1,094,159 and 1,094,160, April 21, 1914.

See Eng. Pat. 14,231 of 1913 ; this J., 1913, 1128.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patent.

Photographic silver-prints ; Process of converting —— into coloured prints. A. Traube, Charlottenburg, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 1,093,503, April 14, 1914.

See Fr. Pat. 376,051 of 1907 ; this J., 1907, 1029.—T. F. B.

XXII.—EXPLOSIVES ; MATCHES.

Mercury fulminate ; Electrolytic determination of mercury in ——. M. S. Losanitsch. Monatsh. Chem., 1914, **35**, 307—309.

The fulminate (0·4 to 0·5 grm.) previously dried at 70°—80° C., is treated with such a quantity of concentrated nitric acid (2·5 to 3·5 c.c.) that after decomposition there shall be sufficient free acid remaining to yield a solution suitable for direct electrolysis. The decomposition is aided by careful warming and finally by boiling. The solution is then made up to about 120 c.c. and electrolysed by an ordinary or a rapid method. The deposit (on a gauze electrode) is washed with water and absolute alcohol, and is then dried over potassium hydroxide in the presence of mercury, and weighed.—W. H. P.

Patents.

Explosive. A. E. Charbonneaux, San Francisco, Cal. U.S. Pat. 1,093,767, April 21, 1914.

A mixture of the ammonium salt of a hydrocarbon sulphonic acid, such as ammonium naphthalenesulphonic acid, potassium chlorate, and potassium permanganate. —O. E. M.

Explosives ; Manufacture of ——. I. B. T. von Tarnow. Fr. Pat. 465,082, Nov. 20, 1913.

Aluminium powder is incorporated with a nitro-hydrocarbon of the aromatic series (*e.g.*, mono-, di-, or trinitrobenzene, aniline tetranitrate, or methylaniline tetranitrate) and ammonium perchlorate, with or without the addition of soluble nitrocellulose and hydrocarbons or carbohydrates, such as paraffin wax, cellulose, etc., and an alkali nitrate the base of which will combine with the chlorine liberated in the explosion, and thus render the explosive suitable for use in mines, etc. Suitable proportions are :—aluminium 9, sawdust or cellulose 9, trinitrobenzene 12, potassium nitrate 30, and ammonium perchlorate 40 per cent.—C. A. M.

Explosives of the Sprengel class ; Manufacture of ——. T. Hawkins, Balmain, N.S.W. Eng. Pat. 17,307, July 28, 1913. Under Int. Conv., Sept. 23, 1912.

See Fr. Pat. 461,332 of 1913 ; this J., 1914, 222.—T F. B.

Nitrocellulose ; Process for the preparation of ——. K. Schniter, Frankfort, Assignor to Verein. Kunstseidefabriken A.-G., Kelsterbach on Maine, Germany. U.S. Pat. 1,093,012, April 14, 1914.

See Fr. Pat. 455,011 of 1913 ; this J., 1913, 886.—T. F. B.

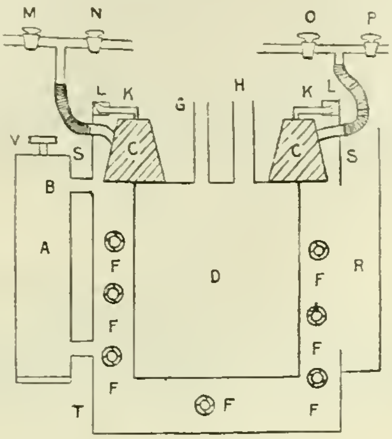
XXIII.—ANALYTICAL PROCESSES.

Tyndall effect in colloidal solutions ; Measurement of the ——. W. Mecklenburg. Kolloid-Zeits., 1914, **14**, 172—181.

The Tyndallmeter devised by the author and Valentiner for measuring the intensity of the Tyndall effect in turbid or colloidal solutions (see Z. Instrumentenkunde, June, 1914), is based on the principle of observing directly the intensity of the Tyndall light in a direction perpendicular to the axis of the rays producing the effect and comparing it with the original intensity of these rays, for which purpose a portion of the beam of light is separated from the remainder and its intensity diminished by means of smoked glasses and a combination of Nicol prisms until it is equal to that of the Tyndall light. The results of some experiments on a colloidal stannic acid solution are given and it is suggested that the Tyndallmeter will prove useful for the comparison of colloidal solutions, for studying coagulation, in the examination of effluents, and in analytical problems.—A. S.

Calorimeter; An adiabatic ——. F. W. Gray. Chem. Soc. Trans., 1914, **105**, 1010—1014.

To reduce radiation losses to a minimum the calorimeter is placed during an experiment, in a chamber, D, which can be kept at a constant temperature. This chamber is a metal vessel immersed in water in a metal vessel, T, and forced upwards by its buoyancy against three corks, C, bearing against arms, K, hinged at L. The water in T is circulated by a stirrer, V, in the chamber, A, and the temperature is adjusted as required by passing hot or cold water through the coil of flexible copper tubing, F, by suitably adjusting the water-taps, M, N, O, P. The temperature of the water in T is observed by a Beckmann thermometer in the chamber, R. Openings, G, H, are provided in D for the thermometer and stirrer of the calorimeter. The apparatus is made of nickel-plated brass, and the flexible copper tube is soldered to brass end-pieces which are joined by rubber tubing to brass tubes, S.—A. T. L.



Flame reactions. II. W. D. Bancroft and H. B. Weiser. J. Phys. Chem., 1914, **18**, 281—336.

From a survey of the available data with regard to the luminosity of gases, it is concluded that an absolutely transparent gas will emit no light at any temperature unless a chemical reaction takes place. A coloured vapour may emit thermal luminescence but it does not follow that all light from coloured vapours is due to thermal causes, even when the radiation has a lower intensity than that of a black body at the same temperature. Since luminescence is often due to chemical action the authors made a qualitative study of the flame reactions of tin and copper and their salts with a view to deciding what reactions cause the luminescence. Care was taken to distinguish between colours due to emission and to absorption respectively. The reaction tin→stannous ion gave a carmine colour, and tin→stannic ion a green colour, the latter being more intense as a rule. The differences between the spectra of the halides of tin were due to differences in the absorption and emission of light by the halogens. In flames containing copper the reaction copper→cuprous ion gave a green colour, Cu→ cuprous salt a red and cuprous ion→cupric ion, or cupric salt, a blue colour. The intensity of the green luminescence was so great that the unaided eye could not distinguish any blue in the ordinary copper flame even though the copper was burning chiefly to cupric salt. The violet red colour of undissociated cupric chloride vapour (observed when chlorine acts upon very hot copper) must not be mistaken for luminescence.—W. H. P.

Manganese reaction; Study of Marshall's ——. E. Schowalter. Z. Unters. Nahr. Genussm., 1914, **27**, 553—562.

Marshall's reaction, which depends on the oxidation of manganese salts to permanganate by means of ammonium persulphate in the presence of silver salts, has been used for the determination of small quantities of manganese in water with good results (see this J., 1913, 447). With quantities of manganese exceeding a few mgrms., however, there is tendency for manganese dioxide to separate out during the oxidation. The following modification enables relatively large amounts of manganese to be determined. The manganese salt (equivalent to not more than 0·2 grm. of manganese) is dissolved in water, 30 c.c. of nitric acid, sp. gr. 1·24, and 8 grms. of ammonium persulphate are added, and the mixture is diluted to 100 c.c.; this solution is then added, in small quantities at a time, to a solution consisting of 10 c.c. of $N/10$ silver nitrate solution, 15 c.c. of nitric acid, 10 grms. of ammonium persulphate, and 35 c.c. of water, this solution having been heated previously to 50° C. The whole is maintained at 50° C. for 10 minutes, then cooled, and the permanganate titrated with arsenious acid solution. The reaction is a catalytic one in which silver peroxide acts as catalyst.—W. P. S.

Nitrates and nitrites; An extremely delicate colorimetric method for detecting and determining ——. E. A. Letts and F. W. Rea. Chem. Soc. Trans., 1914, **105**, 1157—1161.

The diphenylamine reagent for nitrates and nitrites is not suitable for the purpose of a quantitative estimation, but if diphenylbenzidine, the intermediate product of its oxidation to the blue dye, is substituted for it the reaction is available as the basis of a delicate colorimetric method. 0·5 c.c. of the solution to be tested (or smaller quantities made up to this volume if the solution is too strong), are mixed with 1·2 c.c. of sulphuric acid, and 0·3 c.c. of a 0·02 per cent. solution of the reagent in concentrated sulphuric acid, and the colour compared after standing for 10 mins. with that obtained from standard nitrate solutions under similar conditions. Nitrites can be similarly determined after previous oxidation with potassium permanganate.—G. F. M.

Methoxyl [group]; Determination of ——*, in substances containing sulphur.* A. Kirpal and T. Bühn. Ber., 1914, **47**, 1084—1087.

The decomposition of the methoxyl group is effected in the usual way according to the method of Zeisel, preferably with the addition of acetic anhydride. The disturbing influence of hydrogen sulphide upon the determination is eliminated by using pyridine as the absorbent for the methyl iodide: the resulting pyridine methiodide may be titrated directly with silver solution in the absence of pyridine and its salts. A current of hydrogen carries the volatile reaction-products into a receiver consisting of two test-tubes, each containing 3 to 4 c.c. of pyridine, followed by a small flask containing water. The reaction is usually complete after about an hour's heating. The contents of the three receiving vessels are then evaporated as far as possible in a glass dish upon the water-bath. The residue, which crystallises on cooling, is dissolved in water and titrated with $N/10$ silver solution using sodium chromate as indicator. To obtain the best end-point a slight excess of the silver solution is run in; a measure amount of $N/10$ sodium chloride solution is then added and the excess titrated with the silver solution. Result are quoted which show the method to be very accurate —J. R.

Patents.

Gas-tight seals, or closures, between metal and vitreous material [glass]; Production of ——. H. J. S. Sand, Nottingham, and F. Reynolds, Muswell Hill. Eng. Pat. 23,854, Oct. 21, 1913.

Clean surfaces of lead, or other metal or alloy of sufficient plasticity, and vitreous material, such as glass, are caused to adhere so as to remain in perfect contact under varying conditions of temperature, by melting the metal in a vacuum, or in an indifferent or reducing atmosphere, in a space adjoining the point of sealing. Gas-tight joints between vitreous material and metal wire are obtained by introducing or sealing the wire into position, and then allowing lead or similar metal (melted as above) to flow into a cup or recess in the vitreous material so as to cover the projecting end of the wire. If necessary, the seal may be rendered perfect by applying pressure to the surface of the lead (*e.g.*, by admitting air before it solidifies).—F. Sodn.

Photometers; Table ——. C. Carpenter, London. Eng. Pat. 1239, Jan. 16, 1914.

For testing rapidly a number of different samples of gas, separate burners are used, each movable on its own slide and provided with its own connections, meter, governor and cock. The burners can be withdrawn into light-tight boxes. The slides for the several burners are directed radially towards the "photoped" (photometer screen), which is pivoted and is adjusted for each burner so as to be perpendicular to the line bisecting the angle between the beams of light from the testing burner and the standard burner. A small screen is mounted in front of the photometer screen in order to cut off those portions of the beams which would overlap upon the photometer screen. This small screen may be mounted in such a way that its position is adjusted automatically according to the angular adjustment of the photometer screen.—A. T. L.

Apparatus for taking samples of powdered or liquid substances. Eng. Pat. 7354. *See* I.

Process and apparatus for determining by weight quantities of gas, steam or other vapour or liquid. Eng. Pat. 8012. *See* I.

XXIV.—MISCELLANEOUS ABSTRACTS.

Palladium: The rate of solution of hydrogen by ——. A. Holt. Roy. Soc. Proc., 1914, A., 90, 226—237.

The shape of the curves representing the rate of solution of hydrogen by palladium points to the existence of two forms of the metal. The results indicate an initial phenomenon of surface diffusion associated with the α-form of the metal, followed by solution in the β-form. The case appears to be analogous to the "sorption" of gases by charcoal and other solids. Palladium black yields smooth rate curves which denote the absence of one of the forms of the metal.—J. R.

Deliquescence. Part I. Deliquescence of salts of ammonium bases. C. J. Peddle. Chem. Soc. Trans., 1914, **105**, 1025—1039.

The paper deals mainly with a comparison of the deliquescence of the salts of some substituted ammonium bases. The substances (1 grm.) were dried and then sifted until the particles passed through a 30-mesh but were retained by a 60-mesh sieve. They were exposed in weighing bottles of 25 mm. diam., placed in a glass dish over distilled water in a Scheibler desiccator, in the upper part of which was an air fan working at a rapid rate; the whole apparatus was placed in a constant temperature bath at 25° C. The results are given in the form of curves and tables. The rate of absorption varied considerably for different compounds, but was greatest during the third hour of exposure in the case of the most deliquescent compounds and the values of $g \times 1000$ (g = grms. of water absorbed per grm. of substance) at the end of 3 hours were used for purposes of comparison. The compounds giving the highest values were: tetrapropylammonium chloride, 154; diethylamine hydrochloride, 164·9; propylamine hydrochloride, 170·9; tetraethylammonium chloride, 219; dimethylamine hydrochloride, 220·5; ethylamine hydrochloride, 260·5; calcium chloride, 212·8; phosphorus pentoxide, 224·1. Ethylamine hydrochloride in 12 hours absorbed 14 per cent. more moisture than did phosphorus pentoxide.—A. S.

Proteins: Methylation of —— *[by diazomethane].* J. Herzig and K. Landsteiner. Biochem. Zeits., 1914, **61**, 458—463. (See also Skraup and Krause, this J., 1909, 956.)

The finely powdered material was left to stand for ten days with an excess of an ethereal solution of diazomethane, which was subsequently removed by distillation or filtration, and the solid was washed with alcohol, ether and water. By this treatment, repeated in most cases, casein, serum albumin, gelatin, edestin, and silk-fibroin were converted into products containing about 4—5 per cent. of methoxy groups and 4—5 per cent. of methyl groups attached to nitrogen. Control analyses of the substances named, before treatment with diazomethane, gave in all cases positive results, *viz.*, 0·18—0·64 per cent. of methoxy groups (possibly due to traces of alcohol retained by the preparations) and 1·07—1·78 per cent. of methyl groups attached to nitrogen (similar values have been obtained with amino-acids). The nitrogen of protamines and polypeptides appears to be more readily methylated than that of the compounds mentioned above.—J. H. L.

MR. JULIUS HÜBNER IN THE CHAIR.

A NEW PROCESS FOR PRODUCING FAST PRINTS ON TEXTILE FIBRES.

BY DR. HERBERT LEVINSTEIN.

The method usually employed for producing fast prints from coal tar or other dyestuffs depends on the use of (1) mordant dyestuffs; (2) ice colours; (3) vat dyestuffs; (4) oxidation colours. A typical representative of each of these four classes is (1) Alizarin Red; (2) Paranitraniline Red; (3) Indigo Blue; (4) Aniline Black. All these processes have one principle in common. A more or less soluble substance is first applied to the fibre, and is subsequently precipitated inside the fibre in an insoluble form.

The general method of using a mordant dyestuff in calico printing consists in mixing the dyestuff and mordant together into a thickened paste, which will not run, printing or padding, and drying. After drying the goods are steamed, and it is important to note that the combination of the dyestuff and mordant must not take place before the operation of steaming. A premature formation of the lake must be avoided, as it is essential that the fibre should be penetrated by the dyestuff prior to combination with the mordant. For this reason a mordant is usually employed which cannot react during drying, and is only decomposed into its active constituent during steaming.

The new process is due to the observation that a large number of dyestuffs form insoluble compounds when heated with formaldehyde. It depends on exactly the same general principle as the other methods of producing fast prints, and the procedure is very analogous to that in use with mordant dyestuffs. The dyestuffs employed are soluble. They are mixed into a paste with a suitable thickening agent together with formaldehyde, or preferably with a substance which will develop formaldehyde when the printed goods are steamed, and which will not react with the dyestuff during the previous operations of printing and drying.

Such a substance is hexamethylenetetramine, which is readily prepared in a state of sufficient purity by mixing together commercial ammonia with commercial formaldehyde in the correct molecular proportions. The mechanism of the reaction is thus entirely that of the older process. As the goods are steamed the fibre is penetrated by the soluble dyestuff, formaldehyde is slowly set free as the ammonia is driven off, and combines to form an insoluble precipitate inside the fibre. The most interesting results have been obtained with dyestuffs, which like mordant dyestuffs, are true adjective dyestuffs, and have no affinity whatever for the cotton fibre. On the other hand it has also been found possible to print various substantive dyestuffs in the same manner.

At the moment the process is in its infancy, and so far has been used only for the preparation of fast orange, brown and black shades. Preliminary work makes it appear probable that the process is capable of wider development and I venture, therefore, to class it, though with some diffidence, as a new general method for the production of fast prints.

An orange coloured and a black printed cloth have been prepared to show the results obtained respectively with an adjective and a substantive dyestuff. The printing recipes, the fastness of the printed material, and the properties of the condensation products of these two dyestuffs may be taken as typical of a number of dyestuffs wihch have already been investigated. To obtain the orange a simple monoazo dyestuff containing resorcinol as an end component (see English patents 29,021/12, 1123/13 (Cognates), 3427/13 and 4316/13) has been used. This type of dyestuff was among the earliest products made by Peter Griess, the discoverer of the azo dyestuffs, and has been known since 1877. It is remarkable when the extraordinary intensity is considered with which this field has been cultivated and extended since that date, that this reaction with formaldehyde has hitherto escaped observation.

The following is the printing recipe for the orange. The small quantity of formaldehyde used is worth noting, as it indicates the completeness of the reaction.

500 c.c. thickening.
100 c.c. Printing Orange 15 in paste.
5 c.c. neutral hexamethylenetetramine solution.

Thickening.

300 grammes Indian corn starch.
625 c.c. gum tragacanth (6 per cent.).
1250 c.c. water.
60 c.c. olive oil.
60 c.c. glycerin.

Mix the hexamethylenetetramine well with the cold thickening, and then add the colour quite cold. Print, dry, and steam for one hour without pressure. Soap in 0·2 per cent. boiling soap solution for five minutes.

The print is of a bright orange shade, quite fast even to boiling soap solution. The fastness is due to the insoluble nature of the formaldehyde condensation product which has been precipitated within the fibre.

Similar condensation products may be readily obtained in substance. Thus if the dyestuff be treated with a boiling aqueous solution of formaldehyde, either as the free acid or in the form of a salt, sparingly soluble bright orange products are obtained. The substances obtained from the salts and the free acid are in some cases different. These condensation products possess points of interest, and are at present being examined. There seems little doubt that different products possibly polymeric to each other can be obtained by varying the conditions of the reaction.

The black print has been obtained from Vulcan Black GS, a polyazo substantive cotton dyestuff, with the following recipe.

Dissolve 60 grms. of Vulcan Black GS in paste in 180 c.c. boiling water and 3 c.c. caustic soda (3·2 per cent. solution), and add to 20 grms. maize starch and 20 grms. water. Boil, cool down to below 30 C. and add 40 c.c. hexamethylenetetramine solution. Print, dry, and steam for 40 minutes without pressure. The fastness to hot soaping of the printed shade is very good, but the white is just tinted by boiling 1% soap solution.

As in the case of the orange dyestuff described above Vulcan Black GS may be readily condensed with formaldehyde in substance, forming typically colloidal black condensation products practically insoluble in any of the common solvents. In this case too differences may be detected in the products obtained according to the conditions of the reaction.

The formation of what is probably the lowest condensation product proceeds with great rapidity with this dyestuff, which possesses great affinity for formaldehyde.

Discussion.

The Chairman said he had experimented with the orange. The printing process had by no means reached its final stage, though he was of opinion that the method would eventually prove to be a very simple one. The orange produced a very rich colour and quite as fast as Paranitraniline Red. If a whole range of dyestuffs of this type could be introduced they would prove an altogether unique departure in calico printing.

Mr. E. Crowther observed that alizarin colour makers endeavoured to avoid the long steaming referred to by using a Mather and Platt's short steamer. Would this be sufficient, and also would it be practicable to utilise the new process in the presence of an alkaline solution, and would fixation take place in the presence of acid? There were two styles of printing which required those conditions. Apparently the fastness to soap and alkali was very much enhanced, but did such fastness apply to such laundry detergents as chlorine or such home-applied agents as Persil or Omo, which behaved like perborates? The modern test for fast printing was very severe. Many of the alizarin colours were unsuitable for some markets, and it was necessary to employ vat-dyes.

Mr. R. de F. Shepherd inquired whether in addition to being fast to washing the new colours were fast to light.

Mr. L. E. Vlies said they had to go back 15 years to the first use of formalin for the fixation of azo dyestuffs, namely, to Geigy's process for rendering the direct cotton dyestuff Diphenyl Black fast to washing. Probably that dye was not so fast as the Vulcan colours introduced by Messrs. Levinstein, and it also required a greater amount of formalin for its fixation. This process was certainly new to calico printing, and it was very surprising that 15 years should go by, without any novel employment of formaldehyde for improving the fastness of dyes. The use of hexamethylenetetramine was also quite new. He had always been under the impression that this body would not decompose into its component parts in neutral or alkaline solution, but only in the presence of acid. What amount of formalin was necessary to fix the new dyes? Was it excessive, or roughly in proportion to the two molecular weights in question? Dr. Levinstein mentioned the products in substance, and stated that he might find some use for them. That was likely to be the case, especially as they were colloids. The market was in need of new coloured substances for lithographic and pigment printing work. It was satisfactory to learn that the products were soluble in benzene, as they might be used for dyeing in this solution.

Mr. J. Baddiley observed that the phenol-formaldehyde condensation was a very well-known one, but until comparatively recent times chemists had neglected it on account of the non-crystalline nature of the products. The process was explainable by the theory put forward by Baekeland to explain his synthetic resinous products. In the case of a resorcin dye, condensation probably took place through the steps Baekeland described, namely, a benzyl alcohol derivative was first obtained by the action of one molecule of formaldehyde. This intermediate product then condensed with a second molecule of the dyestuff by loss of water, and the process went on repeating itself until a molecule was formed which was resistant to all sorts of action. He was of opinion there was every possibility of obtaining a complete range of shades by this process.

Mr. F. Scholefield said that the condensation product was so readily formed, and was so insoluble, that one would imagine the combination might take place by the decomposition of the hexamethylenetetramine, so that there might be some amount of lake formation before the actual steaming process. It would be interesting to know what could be done in the way of discharges and resists.

Mr. J. Hübner said it was quite possible for a lake formation to take place prior to printing. That was the reason why he had previously stated that the printing process had not reached its finality. Experiments were still in progress. He did not, however, think there would be any difficulty in this respect.

Mr. Gilbert Gunn inquired whether it was possible to dye pulp in the beater or in a revolving boiler.

Mr. Hübner replied in the negative, as practically a boiling temperature would be necessary, unless decomposition could be produced by some addition, or on drying on the cylinders.

Dr. Levinstein stated it had been done in a beater.

Mr. Gunn asked if it was anticipated that the new process would be cheaper than the ordinary process of dyeing. For some classes of paper very deep and fast dyes were required, especially for casings which were largely used in the calico industry, something being required which would not bleed and would stand the action of weak alkali and acid.

Mr. Hübner said experiments would be made in the direction indicated by Mr. Gunn. Possibly decomposition might take place on the drying cylinders, if the colour did not run away on the wire.

Mr. Gunn replied that if the pulp were first treated, and the dye to some extent fixed in the boiler, dyeing being already done in that way, it would be possible to retain a very large percentage by the time the cylinders were used.

Mr. R. de F. Shepherd inquired whether it was necessary to use the hexamethylenetetramine or whether the formalin could not be used directly in the case of dyeing paper pulp.

Dr. H. Levinstein, in reply, said he had not tried this particular substance for dyeing paper pulp, it being merely typical of a large class of dyes which could be made. Several pertinent questions had been asked with regard to the practical value of the printing process, to most of which he was for the moment unable to reply. He had brought the results forward as being more in the nature of an interesting chemical reaction than of a valuable technical process. He was still conducting experiments with regard to the steaming. The condensation took place so readily that he imagined it would be quite feasible to use the small Mather and Platt steamer. Condensation could be, and was preferably, carried out by means of an alkaline printing paste. He believed that an acid printing paste would be unsuitable on account of the fact that the dyestuff was not soluble as a free acid. The fastness to chlorine of the orange dye described was poor, but they had made others which appeared to be much better. The particular substance in question was a mono-azo dyestuff derived from resorcinol. A large number of analogous dyes could be made in that way, of which only a comparatively small number had been tried. He had not tried the action of perborates. The fastness to light of the dyestuff was good, being about equal to that of Paranitraniline Red, but it did not compare with an alizarin dyestuff with regard to fastness to light. The process of J. R. Geigy referred to by Mr. Vlies was one to increase the fastness to washing of substantive dyes by after-treating them on the fibre with formaldehyde. The process described by him was quite a different matter, *viz.*, a new method of producing fast prints with dyes of which many were not substantive, and he had not referred to the Geigy process as this had nothing in common with it.

As regards the constitution of the substances about which Mr. Baddiley had spoken, he had no knowledge of how the condensation products were formed, but he should imagine something of the kind took place: certainly two or more molecules must be linked together in some way. As regards discharging and the use of paraformaldehyde, and the decomposition of the printing paste, nothing had been tried. Premature formation of the lake had been observed, but could be prevented.

SOME NEW DERIVATIVES OF INDIGO.

BY DR. HERBERT LEVINSTEIN.

The first synthesis of indigo was by A. von Baeyer and took place in 1880; it was first marketed in 1897 by the Badische Anilin und Soda Fabrik. The first patent for brominated indigo was taken out in 1900. In this year Rahtjen produced a mixture of indigo, 5-bromo- and 5.5′-dibromo-indigo, known as Indigo R and 2 R, by brominating indigo in glacial acetic acid. In 1907 Engi produced 5-bromo-, 5.5′-dibromo-, 5.7.5′-tribromo-, and 5.7.5′.7′-tetrabromo-indigo by brominating at a higher temperature in a neutral solvent. Penta- and hexabromides have also been obtained by methods which are now well known. It is remarkable that seven years should have elapsed between the discovery of Rahtjen and that of Engi, which has had such valuable technical results.

Friedlaender has recently shown that the active constituent of the ancient Tyrian purple is identical with 6.6′-dibromo-indigo. This substance produces a shade more violet than ordinary indigo, whereas the shade of the 5.5′ isomeride is greener. By this synthesis an interesting link was forged between the dyes of a semi-mythological past with the latest development of modern scientific industry.

In 1905 came the beautiful discovery of thioindigo by Friedlaender. Great activity ensued in the investigation of indigoid dyestuffs in the coal tar dye factories, for these discoveries opened a large field for scientific research which seemed · offer prospects of reaping a technical harvest.

On looking through the notes for those years it seemed to me that the brominated sulphur, selenium, and arsenic compounds of indigo, and 5.5′-dihydroxy-7.7′-disulphonaphthylindigo, a new derivative of β-naphthylindigo, which were prepared at Blackley at that time, may be of some small general interest. The preparation of the first series of compounds is largely due to the initiative of Dr. M. Wyler, who carried out the experimental work, while for the products derived from 5-hydroxy-7-sulpho-2-naphthylglycine I am greatly indebted to the co-operation of Dr. O. Diehl.

There are two publications concerning brominated indigo sulphides, if they may be so called, both by Cassella (see Ger. Patents 220,321 and 220,629 of 1909, since allowed to lapse). In the second patent the formula of the product obtained is given as $(C_{16}H_6N_2O_2Br_3)_2S$.

Our object was to examine this compound and find out whether other substances besides sulphur were capable of entering the indigo molecule in the way suggested by the above formula. Both selenium and arsenic reacted in a very similar manner to sulphur, but unfortunately the analytical data obtained did not enable us to draw any conclusions as to the constitution of the bodies obtained. The preparation of all the derivatives is practically identical in method. To 15 parts of indigo suspended in nitrobenzol 32 parts of bromine are added: 1·8 parts of sulphur, or an equivalent molecular proportion of As, As_2O_3, or As_2O_5 are then added and after 12 hours' standing the mixture is gradually heated up to 180° C. and kept at that temperature for several hours.

As regards the mechanism of the reaction, it should be noted that neither sulphur, selenium, arsenic, As_2O_3, nor As_2O_5 react under the above conditions in the absence of bromine. The formation of the bromo-compound of sulphur, selenium, or arsenic is the first step and this compound then acts on the indigo.

For analysis the dyestuff was in every case reduced to the leuco compound with hydrosulphite, filtered, reprecipitated by means of a current of air and dried.

In the case of the sulphur compound the figure for sulphur corresponded fairly well with the above formula. In the cases of selenium, arsenic, As_2O_3, and As_2O_5, the figures for selenium and arsenic were considerably lower. The As_2O_5 is the most reactive of these substances and the tribromo-indigo derivative prepared in the presence of As_2O_5 contained 5·19 % and 5·25 % As.

The introduction of sulphur, selenium, or arsenic into the indigo ring has but little effect on the shade. Thus all the tribromo derivatives give shades similar in character to those of tribromo-indigo. In the case of the arsenic indigos, mono-, di-, tri-, and tetrabromo derivatives were made, and in each case the arsenic derivatives correspond roughly in shade with the derivatives of indigo containing the same quantity of bromine.

The preparation of 5·5′-dihydroxy-7.7′-disulphonaphthylindigo is interesting on account of the very smooth manner in which it may be obtained from 5-hydroxy-7-sulpho-2-naphthylglycine, 20 grms. of which are slowly and carefully added to 60 c.c. concentrated sulphuric acid at 100° C. The temperature is then raised to 170° until no further reaction is observed. After cooling, the brownish yellow sulphuric acid solution is poured on to 300—400 grams of finely ground ice and the indigo is filtered off, washed with ice water, and dried on the water bath. Yield 19 grms. The substance has a strong bronzy lustre and exhibits a characteristic dichroism. It is sparingly soluble in cold water, more readily in hot. On the addition of caustic soda the aqueous solution is nearly decolorised, showing only a faint green coloration. With soda there is no discoloration in the cold, but on heating the solution becomes green. The colour of the alkaline solution is discharged by heating with hydrosulphite. When dissolved in concentrated sulphuric acid it produces a beautiful fluorescence and a deep blue solution when poured into cold water.

The new substance dyes a green shade on wool from a weakly acid bath, and also possesses a noticeable affinity for the vegetable fibre, as might be expected from the orientation of the substituent groups in the naphthalene nucleus.

Bromination takes place readily in glacial acetic acid, four atoms of bromine being taken up. The bromine compound is soluble in alcohol, and more soluble in water than the unbrominated compound. The bright blue aqueous solution becomes green on the addition of caustic soda; a much more intense shade than that of the unbrominated compound. Melting either the brominated or the unbrominated product with alkali leads to complete breaking up of the molecule, but by the action of 30 per cent. fuming hydrochloric acid a substance was obtained which is in all probability tetrahydroxynaphthylindigo.

Discussion.

Mr. **Hübner** said that for cotton dyeing indigo was being gradually replaced by dyestuffs which produced faster shades. As regards wool-dyeing indigo still maintained its position. The Committee of the Textile Institute appointed to go into the question of indigo-dyed cotton goods had only held one meeting and then dissolved. Upon that Committee was a representative of the Admiralty, who stated that the Department had used nothing but indigo for the blue collars which the sailors wore, but they were now on the look-out for a colour faster than indigo, which they thought they could obtain.

Mr. E. **Crowther** considered there was something in the process of dyeing with indigo which caused part of the colour to be absolutely fast to washing. Had the author made any dyeing experiments with derivatives of indigo? There appeared to be a tremendous amount of waste colour on indigo-dyed cotton of deep shades, and if it were possible to dye a lighter shade of similar fastness to the residual colour obtained by a heavy soaping of a deep shade, naval men would be satisfied.

Mr. **Hübner** stated that it was well-known that very light shades were most difficult to remove by washing, even in the case of ordinary direct dyeing colours.

Mr. L. E. **Vlies** observed that in the author's description of the progressive bromination of indigo, two particular positions in the molecule remained unattacked. He was not quite clear which these were, as two methods of indicating them were possible. They could be positions 4.4′ or 6.6′. If Dr. Levinstein adapted the method of starting the count from the imido group counter clockwise on the left side of the formula, then he was correct in his statement. The 6.6′-dibromoindigo, one of the dyestuffs present in the mollusc, *Murex brandaris*, could only be obtained indirectly, such as by the internal condensation of the glycine of 4-bromo-2-aminobenzoic acid. It was remarkable that on further bromination, this body still gave reddish-violet dyestuffs, whereas the products of the direct bromination of indigo gradually became greener and weaker in shade. It was of interest to note that the hexabromo-indigo contained over 65 per cent. of bromine. Such a large nonchromophoric addition to the molecule would readily account for the diminished tinctorial power.

Mr. **Clegg** asked whether the author had succeeded in introducing arsenic and selenium into thioindigo.

Dr. H. **Levinstein** agreed that indigo was a poor cotton dyestuff in comparison with modern dyes, though perhaps it was still the finest wool dye. Alizarin or anthracene blues would stand originally a longer time without fading, but when they had finished their work they mostly did so as a dirty puce colour, while indigo, though becoming weaker, retained its blue colour. For that reason alone indigo ought to hold its own on wool for many years to come. With regard to Mr. Vlies' query concerning the constitution of Tyrian purple, the statement made in the paper was correct. In reply to Mr. Clegg, they had been content with preparing the selenium and the arsenic derivatives of indigo, and did not pursue the matter further. There did not appear to be any prospect of selenium or arsenic derivatives finding technical application.

New York Section.

Meeting held at Chemists' Building, on Friday, April 24th, 1914.

MR. G. W. THOMSON IN THE CHAIR.

THE CHEMISTRY OF PINE OIL.

BY MAXIMILIAN TOCH.

One of the industries which has developed as a result of the policy of conservation in the United States is the manufacture of useful products from resinous woods. Enormous quantities of the latter, which in previous years were considered of little or no use and were deliberately burned in huge burners especially constructed for the purpose, or which were simply allowed to go to waste, are now being economically and profitably manipulated for the recovery of turpentine, pine oil, and rosin, or the production of tar oils, pine pitch, and charcoal.

The two commercially important methods in vogue are, first, the steam and solvent or extraction process, and second, the destructive distillation process.

Mr. H. T. Yaryan has taken out letters patent on a process for extracting turpentine and rosin from resinous woods, which very well illustrates the extraction method as practised to-day. Resinous wood, reduced to fine chips by passing through a wood chipper, is charged into an iron vessel through a charging door at the top. The wood rests upon a false bottom over a coil supplied with superheated steam for producing and maintaining the proper temperature within the iron chamber. The door at the top and the discharge door at the bottom are closed, and the current of superheated steam is driven into the mass of chips. This is continued until the more volatile turpentine has been vaporised and driven over into the condensers. The wood in the extraction vessel is left charged with a small percentage of heavy turpentine, together with pine oil and rosin. Steam is shut off, the excess moisture in the hot wood is removed by connecting the vessel with a vacuum pump, and finally a liquid hydrocarbon (b.pt. 240°—270° F.) is sprayed over the top and allowed to percolate down through the pores of the wood. The resinous materials are thus thoroughly and completely extracted, and passed into a storage tank, from which they are pumped into a still used for separating the component parts of the solution. From the still the hydrocarbon solvent is readily separated from the heavier pine oils by distillation under reduced pressure, on account of the great difference in the boiling point between the pine oils and the hydrocarbon solvent, the former boiling between 350°—370° F. The pine oils are in turn separated from the rosin by distillation with superheated steam.

This process has been worked on an enormous scale by the Yaryan Naval Stores Company[*], with plants at Brunswick, Ga., and Gulfport, Miss. This Company's Brunswick plant alone utilises from 500—600 tons of wood each 24 hours—probably a larger consumption than the combined pine wood destructive distillation plants of the country.

Other so-called "low temperature" processes deserve mention as possessing features of merit, although sufficient data does not appear to be available to show their true value when operated on a large commercial scale. The Hough process, for example, is to be considered essentially a preliminary treatment in the manufacture of paper pulp from resinous woods. Chipped wood is placed in a retort and subjected to the action of a dilute alkali. The rosins are saponified and the soap separated from the alkaline liquor by cooling and increasing the a kali concentration to the desired degree. The rosin soap may be sold as such, or treated with acids for recovery of the rosin. The turpentine and pine oils are recovered either by preliminary treatment with steam or during the early stages of the cooking process.

It will be noted that in the low temperature processes the only products recovered are turpentine, pine oils, and rosins, the first two removed by the action of steam, either saturated or superheated, and the latter by extraction by use of a neutral volatile solvent or a saponifying agent. The so-called "spent wood" may be used either for the manufacture of paper pulp or as a fuel to generate the power necessary to carry out the process.

In the destructive distillation process, the wood, in the form of cordwood 4 ft. to 6 ft in length and 4 in. to 8 in. in diameter, is placed in a horizontal retort and the temperature gradually raised until the wood is thoroughly carbonised. The factor of greatest importance in the successful operation of this process is temperature control, as it is essential that the turpentines and pine oils be removed in so far as is possible before the temperature at which the resins and wood fibre begin to decompose is reached. The total volume of distillate, as well as the percentage volume of each of the several fractions thereof, is largely dependent on the degree of temperature control.

Destructive distillation of resinous wood was first carried out in earthen trenches, the combustion being controlled by partially covering the wood with earth. Tar and charcoal were the only products recovered. Then came the beehive oven, operated in much the same crude manner, but recovering the more volatile distillates, in addition to tar and charcoal. This was in turn superseded by the horizontal retort, externally heated, hot gases being circulated either through an outer shell or through pipes within the retort. Next came the bath process, wherein the cord wood was immersed in a bath of hot pitch or rosin, thereby volatilising the turpentine and lighter pine oils and dissolving the heavier oils and rosins. After this preliminary treatment the bath was withdrawn and the wood subjected to straight destructive distillation.

More recently[*] a retort has been devised utilising the basic principle of the laboratory oil bath. The retort is heated by means of a layer of hot petroleum oil which is kept continually circulating between the retorts and an outer cylindrical shell that completely surrounds the retort proper. In this way it is claimed that the temperature of distillation can be accurately controlled. The turpentine and pine oil obtained are fractionated and rectified by subsequent steam distillation. In running the retort the temperature of the oil bath is so regulated that the heat inside does not exceed 450° F. before all the turpentine and pine oil have been distilled.

The products of destructive distillation by the severa processes are in each case of very much the same genera nature, namely, turpentine, pine oils, tar oils, pine tar pitch, and charcoal. In some instances low grade rosi oils are also produced.

"Light wood" does not refer to woody fibre which has low specific gravity. The name originated from the fac that this particular wood is so rich in oil and resino material that it is readily used for lighting fires. In th southern portion of the United States little bundles "light wood" are for sale in strips about ¼ in. in diamet and 1 in. long. When a flame is applied to one of the strips of wood it becomes useful for lighting fires, hen the name "light wood." I have seen "light wood" rich in resins and oily material that by transmitted lig a thin section looked like translucent ruby glass. It this particular wood which is most used for the distillati of wood turpentine, pine oil, and rosin.

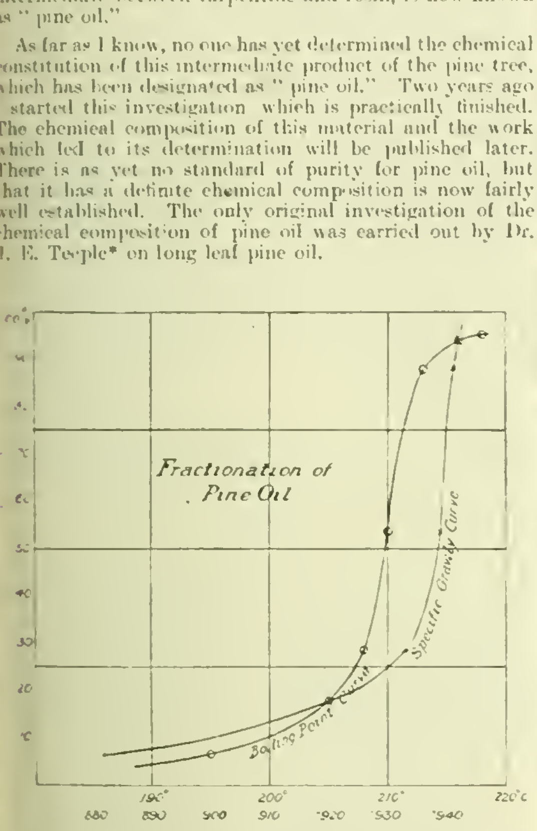
[*] T. W. Pritchard, this Journal, 1912, **31**, 418.

The product from that type of pine tree from which turpentine is obtained has always been regarded as producing two materials when the sap has been collected and distilled. The one material is turpentine, and the other rosin. About ten years ago, when destructive and steam distillation of pine wood became a practical industry, a third substance was recovered. This material, intermediate between turpentine and rosin, is now known as "pine oil."

As far as I know, no one has yet determined the chemical constitution of this intermediate product of the pine tree, which has been designated as "pine oil." Two years ago I started this investigation which is practically finished. The chemical composition of this material and the work which led to its determination will be published later. There is as yet no standard of purity for pine oil, but that it has a definite chemical composition is now fairly well established. The only original investigation of the chemical composition of pine oil was carried out by Dr. J. E. Teeple* on long leaf pine oil.



Dr Teeple says: "The commercial long leaf oil, as it comes on the market, is either clear and water white, containing 3 or 4 per cent. of dissolved water, or it may have a very faint yellow colour and be free from dissolved water. The specific gravity ranges from 0·935 to 0·947, depending on freedom from lower boiling terpenes. A good commercial product will begin distilling at about 206° to 210° and 75 per cent. of it will distil between the limits 211°—218°, and 50 per cent. of it between 213°—217°. A sample having a density of 0·945 at 15·5° showed a specific rotation of about $[\alpha]_D^{20^\circ}$—11°, and an index of refraction of N_D 1·4830. In fractional distillation of the oil the specific gravity of the various distillates rises regularly with increasing temperature, becoming steady at about 0·947 at 217°.

"If the oil consists essentially of terpineol, $C_{10}H_{18}O$, it should be easy to convert it into terpin hydrate, $C_{10}H_{20}O_2+H_2O$, by the method of Tiemann and Schmidt.† The conversion was found to proceed easily when the oil was treated with 5 per cent. sulphuric acid, either with or without admixture with benzine. If agitated continuously, the reaction is complete within 3 or 4 days. If, on the other hand, the mixture is allowed to stand quietly, the formation of terpin hydrate extends over several months and produces most beautiful large crystals, which, without recrystallising, melt at 117°—118°. When recrystallised from ethyl acetate they melt at 118°. The yield is about 60 per cent. of the theoretical. This forms such a simple, cheap, and convenient method of making terpin hydrate that it will doubtless supersede the usual manufacture from turpentine, alcohol, and nitric acid, and instead of terpin hydrate serving as raw material for the manufacture of terpineol, as heretofore, the reverse will be the case."

The term "pine oil," as now understood, is the heavy oil obtained from the fractionation of crude steam distilled wood turpentine. When the sap of the pine tree is subjected to distillation in a current of steam the volatile liquid—turpentine—consists almost entirely of the hydrocarbon, pinene ($C_{10}H_{16}$). When, however, the trunk, stumps, and roots of the same tree have been allowed to remain on the ground for a number of years and are then steam distilled, there is obtained, in addition to the turpentine and rosin, certain heavier oils formed by hydrolysis and oxidation as a result of exposure to the atmosphere. To the heavier oils thus formed and yielded up in the process of steam distillation the term "pine oil" is properly applied.

Pure pine oil has a very pleasant aromatic odour, similar at times to the oil of caraway seed or the oil of juniper seed. When pine oil is impure it is very difficult to use it for interior work on account of its pernicious odour of empyreumatic compounds. It has been used to a considerable extent for making paints which should dry without a gloss, and as a "flatting" material it has been very successful. It has the excellent quality of flowing out well under the brush and of not showing brush marks, the latter because it evaporates so very slowly. It is a very powerful solvent, and many of the acid resins which have a tendency to separate when they are insufficiently heated with drying oils will remain together when pine oil is added. Pine oil can be used to a considerable extent as a diluent in nitrocellulose solutions, and as a cooling agent for the reduction of varnishes it also has excellent qualities. The author takes this opportunity of stating that on previous occasions his recommendations concerning new and useful materials for the paint and varnish industry have been misunderstood in some instances, and it is to be hoped that these remarks will not be misinterpreted. Pine oil is a new and useful material, but it is by no means a substitute for linseed oil or turpentine or any of the other materials now on the market. It has properties peculiar to itself, and when intelligently used is of considerable value.

Practically all the pine oil obtainable contains a small percentage of water in solution, to which it clings rather tenaciously, and it is by no means a simple matter to dehydrate this material. A rather complex apparatus for dehydrating the material is necessary with temperature control, but the test which the author has devised for the determination of water is quite simple. If 5 c.c. of pine oil are mixed with 1 c.c. of a neutral mineral oil, like benzine, kerosene, or benzol, and a perfectly clear solution is obtained on shaking, no water is present; but if there is any water present in the pine oil the water appears as a jelly, and a milky solution is obtained which does not separate after long standing. The fact that pine oil will take up a considerable quantity of water and still remain clear makes it useful for emulsion paints such as are very much in vogue at the present time for the interior of buildings, and it has been suggested that the addition of water up to 5 per cent. for such a purpose is beneficial on new walls. The United States Bureau of Chemistry* has developed a method for the determination of moisture by the use of calcium carbide; this is being investigated at our laboratories, but on account of its being a gas-volumetric method is not quite feasible for general use in technical laboratories.

I am glad to acknowledge here the assistance which was given to me by Mr. C. A. Lunn for the samples of raw materials and information sent me.

A number of commercial samples of pine oil were dehydrated and analysed. The tables given below indicate the results obtained:—

Nottingham Section.

Meeting held at Nottingham on Wednesday, April 29th, 1914.

MR. S R. TROTMAN IN THE CHAIR.

SOME PRACTICAL OBSERVATIONS IN THE PREPARATION OF LIME-ARSENIC PAINTS.

BY R. FARADAY INNES, F.I.C.

The great irregularity in the physical state and chemical composition of lime-arsenic paints led me to test the effect of altering the various conditions of preparation.

Text-books on tanning recommend that red arsenic should first be sprinkled over the lime, hot water added, and the mixture stirred; this practice is followed by the trade and is presumably regarded as the best.

I find that this method does not give the best results, judging by the amount of sulphydrate-ions formed. This was considered to be the only determination necessary, and was carried out using Blockley and Mehd's method (this Journal, 1912, 369) with E/5 nickel chloride as external indicator.

The first experiments were done in 6 in. open dishes, but it was found that there was considerable loss of SH-ions after about ¼ hour, especially if the mixture was kept warm, owing most likely to oxidation. This oxidation is not so likely on a large scale, so further experiments were conducted in long-necked 500 c.c. flasks in order to approximate to working conditions.

On using calcium hydrate and hot water a higher result was obtained than by the usual method. So I tried slaking the lime first and then adding red arsenic immediately the slaking was over. Higher and more consistent results were obtained.

The influence of time and temperature are shown in the subjoined table. In experiments A to D. 13·2 grms. of calcium hydrate were treated in a dish. and in E to G in a flask. Experiments H and I were made by treating 10 grms. of quicklime in a flask :—

* In hot flask kept corked. † Evaporated to dryness in ½ hour. ‡ Slaked together.

Experiments on a larger scale confirmed these results and conclusions.

It was further found that lime slaked in such a way as just to boil the water but not to cause excessive ebullition. gave a paint (whether with or without the arsenic) very much finer and more voluminous than by slaking with small quantities of water at a time. This latter method caused hard lumps of unslaked lime, due to local overheating (Procter's Principles of Leather Manufacture, pp. 122 and 142)

Expressed briefly the conclusion arrived at is:—Let the lime be as fully hydrated as possible, and yet as hot as possible before adding the red arsenic. Then stir very thoroughly. Do not let the lime slake dry and crumble.

This confirms the work of Levi and Manuel published in "Hide and Leather," May 7th, 1910.

Working on a large scale it was not found possible to get exactly the same results every time. This is partly due to the fact that the paint is always made as nearly as possible to the same consistency regardless of the amount of water required, this latter being a variable quantity.

Another observation was that a red arsenic containing about the same amount of sulphur as another does not necessarily give the same amount of sulphur into solution as sulphydrate, whether slaked as above or in the usual way. With a good red arsenic containing say 37 per cent. of total sulphur one ought to get about 32 per cent. into solution, equal to about 86½ per cent. calculated on the total sulphur. I have had, however, numerous samples of red arsenic only yielding 20·4 per cent., 17·6 per cent., and 16·0 per cent. "available" sulphur, and a sample of yellow arsenic only yielded 11·2 per cent., though its total sulphur was 32·6. This is obviously a different material to the usual yellow arsenic, as Prof. Procter states that he obtains even better results with yellow than with red.

Although red arsenic is said to be realgar (As_2S_2) containing 29·96 per cent. S, samples I have analysed contain from 34—37 per cent. As_2S_3 (yellow arsenic) contains 39·09 per cent. S.

Therefore in examining deliveries a total analysis does not give nearly such useful information as a determination of the "available" sulphur. For this, a method based on F or H has been found to give reliable results.

DISCUSSION.

Mr. R. F. INNES, in reply to a question from Mr. Law, said that no experiments with larger proportions of arsenic had been made, because in his own case it never exceeded 10 per cent., and generally was about half that. Prof. Stiasny had found that arsenic must not be in excess, even locally, and when adding it the mixture must be well stirred. The sulphydrate ions, in conjunction with the OH ions, were the active unhairing principle. In reply to Mr. Pentecost, the arsenic itself, so far as was known, played no part in unhairing, and only a small part went into solution, not even enough to kill the bacteria present. A mixture of sodium sulphide and calcium chloride was not in favour with tanners. In reply to Mr. Merriman, the insoluble arsenic was removed with the hair, and the soluble arsenic with the hydrate and sulphydrate by washing.

NOTE ON THE RELATION BETWEEN THE "FEEL" OF LEATHER AND ITS APPEARANCE UNDER THE MICROSCOPE.

BY R. FARADAY INNES, F.I.C.

The following remarks refer to chrome-tanned goatskins for glacé-kid. The photographs are from the finished leather and are magnified 75 times.

The sections were prepared by shaving in sections parallel to the fibres of the skin as thinly as possible by hand with a razor (not with a microtome). The width of the sections averaged 0·17 mm. They were then teased out as thoroughly as possible with needles. It was very much easier to tease out sections of mellow well-feeling skins than sections of hard tinny skins: in all cases of the former the section could be teased out as easily as cotton-wool, but in the latter cases the section seemed more like a piece of thick string, and it was only possible to separate the skin into "lumps." These consisted of masses of fibre still cemented firmly together. Where the fibres are stunted and short this has been caused by their having originally been cemented together so firmly that on attempting to tease them out they have been torn. Had the interfibrillar cement been removed the fibres

themselves could have been separated whole. Thus a long-fibred section is an index of nice feeling, soft, mellow leather, and a short-fibred one, of hard leather.

Figures are calculated on undried sample.

Where the fibres are well separated but are fragile-looking and have a lot of loose ends and a "shaggy" or "ragged" appearance, this is due to excessive action of calcium hydroxide. In this particular example the skin had been in a fresh lime-liquor an extra three weeks and was characterised by a "break" and also stretchiness.

A similar lot of skins had an extra three weeks in a mellow liquor instead of a fresh liquor. This turned out very well and had no break.

The photos show examples of:—Under-liming (fibres short and stuck together); proper liming (fibres long, well defined, and sound—nothing but fibres); and over-liming (fibres long but "ragged" and fragile).

Another small point of interest is that as the fibres approach from flesh to close under the grain they get finer and merge into a much more compact formation, and the chromium content of the grain-side is about half as much again as in the middle and flesh-side as shown by the figures in the foregoing table.

This short note confirms Prof. Procter's remarks on the great use of the microscope in leather chemistry. Chemical analysis shows all the skins to contain the normal amount of chromium, but gives no information as to possible causes of harshness, tinniness, or break in the leather. It seems to me that this method of examination should be applied systematically in the earlier stages and that in liming control, analysis of liquors should be supplemented with a micro-examination of the fibres in a

manner similar to the examination of steel-rails, etc., where chemical analysis is of little real value unless supported by metallographic examination.

I will conclude by expressing my indebtedness to the Board of Directors of the British Chrome Tanning Company (1909), Ltd., for permission to publish these results obtained in their laboratory.

Discussion.

Mr. S. R. **Trotman** said that the paper showed how a chemist, by the aid of the microscope, could find out things which could not be discovered in any other way.

Mr. D. J. **Law** noted the different chromium content in the two sets of figures, and wondered if there were any corresponding difference in the character of each. The pieces of leather and their corresponding photographs showed very clearly the underlying cause of the difference in the feel of the skin. The higher chrome content of the grain might throw some light on its constitution.

Mr. S. J. **Pentecost** suggested that treatment with sulphonated oils might possibly affect the feel of the leather.

Mr. R. F. **Innes**, in reply, said that the skin with the higher chromium content was very well-feeling and supple, and of better quality than the other; but he had come across well-feeling supple leather with the lower chromium content, so that this really was not such an important factor as the condition of the fibres.

Obituary.

WALTHER FELD.

Walther Feld was born on November 4th, 1862, in Neuwied, Germany. He was educated in Zürich, Leipsic, and Munich, and then acted as assistant to Professor Rüdorff in Berlin. Participating in the production of Fehling's Handwörterbuch, his first independent step was one of a literary character. With Professor G. von Knorre he succeeded in devising a method for separating manganese and iron, and in a method for preparing a copper silicide, patented in 1888, and leading to the successful production of silicon-bronze. After engaging in the manufacture of barium carbonate and oxide, and hydrogen peroxide, and in founding large works for these industries, he turned his attention to the extraction of the sulphur of gasworks residues, and of cyanogen from crude coal gas, and he devised an apparatus, known as Feld's gas-washer, for the removal of the sulphur and cyanogen compounds from coal gas. Feld succeeded in solving the problem of so extracting from the crude coal gas the sulphur and ammonia as to produce directly ammonium sulphate, thus utilising the sulphur of the crude gas to replace that from other sources, otherwise represented by the sulphuric acid employed in the usual ammonium sulphate process. To this end the crude coal gas is washed with an ammonium polythionate solution, the polythionate becoming reduced by the sulphur of the gas to ammonium thiosulphate with separation of pure free sulphur. This sulphur is burnt to form sulphur dioxide, with which the thiosulphate is re-converted into polythionate. When the wash liquor is thus sufficiently concentrated by enrichment with polythionate, the latter by heating is converted into ammonium sulphate, sulphur, and sulphurous acid. The two latter return to the cycle of operations, the ammonium sulphate being recovered by mere evaporation of the solution.

Walther Feld died on the 15th March at Linz-am-Rhein.

JOSEPH WILSON SWAN.

Born in Sunderland, October 31st, 1828, Sir Joseph Wilson Swan, D.Sc., F.R.S., was early destined for a scientific career. Indentured as apprentice to a pharmaceutical chemist in Sunderland, he found himself in congenial surroundings. The routine gave him an excellent training for in those days the pharmacist had to make many chemicals which are now prepared on the manufacturing scale.

Another formative influence in Swan's life was his hearing a lecturer of that day named Stait who, among other things, showed his audience a small incandescent lamp the filament of which was made of iridio-platinum. This afterwards brought about the experiments which culminated in the carbon filament now so familiar to everyone in the Edison-Swan lamp. Leaving Sunderland, he joined Mr. Mawson, chemist, Newcastle-upon-Tyne, first as an assistant and later as a partner. Swan was the means of introducing, as part of the business, the manufacture and supply of philosophical and scientific apparatus, and here too he began the manufacture of collodion for photographic purposes in which industry his firm were the pioneers. The nitrocellulose required was prepared by Sir Joseph himself, and for many years he devoted time and thought to improvements in its manufacture. His next achievement was the discovery of how to increase the sensitiveness of dry plates, and he was the first to produce the "rapid plate." So far back as 1882, a Swan plate photographed a flash of lightning in the ten-thousandth part of a second.

He was, perhaps, the first fully to grasp the advantages of carbon as a material for the filaments of incandescent lamps. By 1860 he had made carbon filaments by heating strips of paper packed in crucibles with powdered charcoal, and, mounting these carbonised strips in glass vessels exhausted of air, he raised them to a red heat by means of an electric current from primary batteries. But the vacuum was imperfect and the carbons soon burnt up. He returned to the question 17 years later and found that, in really high vacua such as were obtained by the Sprengel mercury air pump, carbon filaments were durable. At first the filaments were made by carbonising paper, then by dipping thread in sulphuric acid, and lastly by squirting collodion into a coagulating solution. Suitable lengths of the tough threads were packed in charcoal and carbonised in a kiln. In February, 1879, he exhibited his lamp at a meeting of the Newcastle Chemical Society, and the first considerable display took place at the Newcastle Literary and Philosophical Society on October 20th, 1880. In the meantime, Edison had been working independently on the subject, and various questions of priority arose which later were amicably settled.

Swan also invented the autotype carbon process. He employed a tissue "as pliant as paper and smooth as glass, formed of collodion on the one side, and of gelatin impregnated with ammonium bichromate, carbon (Indian ink) and saccharine matter (sugar) on the other." The process was at once adopted, notably in France. Swan found that the greater or smaller relief in carbon prints in the parts more or less acted upon by light afforded a means of forming a metallic matrix by electro-typing or by pressure in soft metal, and the prints so yielded, constituted, by a species of casting, facsimiles of the original carbon picture in gelatin. He so modified the process that an electrotype of a granular carbon print could be adapted to ordinary copper plate printing, thus devising the first practical photogravure process

He was a co-inventor of Woodbury type, and, with Mr. Kendall, of a process for making cyanides from atmospheric nitrogen, carbonate of potash, and carbon. He also made improvements in accumulators by devising a method of making cellular lead plates, by which the capacity of the batteries per unit of weight was increased.

At the Inventions Exhibition in 1885, he exhibited not only threads and fibres, but woven fabrics of artificial silk; he did not, however, follow the matter up. He devised the first miner's electric safety lamp. During his researches on electrotyping he observed accidentally that the addition of a little gelatin to the bath much improved the quality of copper deposits. The outcome of this observation was the utilisation of currents of from 1000 to 1500 ampères per sq. ft. of cathode, and the reeling of copper wire during electro-deposition from the bath through a die.

Swan was active in many fields. He took out more than sixty patents. He was elected a Fellow of the Royal Society in 1894. The Legion of Honour was bestowed on him in 1881. He was made a Knight in 1904, in which year also the Royal Society granted him the Hughes Medal. He received the Medal of the Society of Chemical Industry in 1902. He was President of the Institution of Electrical Engineers in 1898–99, of the Society of Chemical Industry in 1900–1901, and of the Faraday Society in 1908. The City of Newcastle was about to present its freedom to him when he died on May 27th in his 86th year.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows; Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris 3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

Lubricating oil; Repeated use of —— after filtration. G. F. Fenno. Min. and Eng. World, 1914, 40, 835—836.

In an installation fitted with a Richardson central oiling and filtering system, a high-grade mineral oil was supplied continuously to the bearings, and after filtration and removal of water was used over and over again. After 18 months the oil was found to have increased somewhat in sp. gr. and viscosity, owing to admixture with some of the cylinder oil. The fresh oil showed a slightly lower coefficient of friction on low-bearing pressures, whilst the friction coefficient of the filtered oil was lower on higher-bearing pressures, but the difference was so small as to be negligible under working conditions. The saving in cost of oil with a plant using two Richardson filters, each taking about 75 galls. per hour, is estimated at $2000 (£410) per month.—C. A. M.

Rate of evaporation in a vacuum pan. Deerr. *See* XVII.

Patents.

Centrifugal machines. H. Broadbent, Huddersfield. Eng. Pat. 8376, April 9, 1913.

A differential motion between the feed screw and the basket is obtained by means of gearing which is either carried by and rotates with the centrifugal members, or one of them, or is mounted on but not rotated with them. —W. H. C.

Centrifugal extractor. E. F. Poland, Boston, Mass. U.S. Pat. 1,094,589, April 28, 1914.

The extractor is carried and driven by the shaft of an electric motor arranged vertically beneath it, the end of the shaft being supported in a socket carried by a spherical boss attached to the casing of the motor. The boss is mounted in a spherical step-bearing on the base-plate of the machine, which also carries two upright shafts mounted resiliently and passing through sleeves carried by arms projecting radially from the motor casing. The shaft may thus oscillate in all directions.—H. H

Hydro-extractor. E. F. Poland, Boston, Mass. U.S. Pat. 1,094,590, April 28, 1914.

In a hydro-extractor having a belt drive, the belt pulley is controlled by a lever connected with the lid of the extractor, so that the machine can only be started when the lid is shut.—H. H.

Rotary mixers and like machines, and process for mixing bituminous material with stone and sand by the application of heat. L. F. Kaye, New York, and The British Silicate Engineering Co., Ltd., London. Eng. Pat. 8599, April 11, 1913.

The perforations or gratings in the "risers" or agitator blades are provided with means by which they can be opened or closed at will so as to retain the materials or allow them to pass through. Steam, gases or other materials can be introduced or withdrawn from the mixer through hollow trunnions which carry the agitating gear.—W. H. C.

Separating liquids from elastic fluids [e.g. water from compressed air]; Apparatus for ——. B. Woollard, Catford, and P. Brotherhood, Ltd., Peterborough. Eng. Pat. 11,733, May 20, 1913.

The air and water enter the top of a cylindrical chamber and are deflected towards the periphery by a conical deflector. Immediately below is the conical top of a float which again deflects the liquid outwards and allows the air or gas to enter the body of the float and so reach the gas-discharge pipe which extends downwards from the top of the vessel into the interior of the float. When sufficient liquid has accumulated in the bottom of the vessel the float operates the liquid-discharge valve. —W. H. C.

Furnaces. C. D. McCourt, Streatham Common, Surrey. Eng. Pat. 12,952, June 4, 1913.

The materials to be heated are placed in a closed chamber provided with doors for access to the interior and with heating tubes which extend transversely across the chamber. The whole is placed within a furnace and the materials are heated by transmission through the walls of the chamber and the tubes and through the closing doors.—W. H. C.

Deposition of carbon in reversing furnaces; Method of preventing ——. F. Tschudy, Birmingham, Ala. U.S. Pat. 1,093,895, April 21, 1914.

When changing over the regenerators of a set of coke-ovens or other regenerative reversing furnace, air is drawn through both systems of regenerators for a short time, to remove remaining products of combustion and any carbon residues.—W. H. C.

Measuring the velocity of flow of gases and vapours; Apparatus for ——. J. T. Morris, London. Eng. Pat. 25,923, Nov. 12, 1913.

The wires of a Wheatstone bridge are exposed to the gas current and the alteration in the resistance due to the cooling effect of the current is compared with the resistance of similar wires which are sheltered from the cooling effect of the stream of gas. The instrument is calibrated to indicate the velocity of the gases in suitable units.—W. H. C.

Pouring wet, adhesive masses into drying pans or the like; Apparatus for ——. Act.-Ges. fur Anilin-Fabrikation, Berlin. Eng. Pat. 1355, Jan. 17, 1914. Under Int. Conv., Aug. 27, 1913.

The wet mass is discharged from the filter-press or other apparatus into a box closed at the bottom by a slide. On withdrawing the slide the mass descends until it rests on a tray placed beneath the box. The slide is then pushed back, cutting off a slab of the material, which is spread out in an even layer by a "nose" or wire attached to the front end of the slide.—W. H. C.

Drying gases; Apparatus for ——. C. H. Leinert, Chicago, Ill. U.S. Pat. 1,093,869, April 21, 1914.

The apparatus consists of a pair of concentric annular "equalising chambers" having a cooling chamber between them and another cooling chamber within the inner "equalising chamber." A number of pipes pass through each of the "equalising chambers" and communicate with the inner cooling chamber so that the gas flowing from the inner chamber serves to cool the gas passing through the "equalising chambers."—W. H. C.

Filter. O. M. Lamsens, Detroit, Mich. U.S. Pat. 1,093,999, April 21, 1914.

A drum formed of cylindrical sections and having dished ends all bolted together, is rotated by means of hollow trunnions which serve also as inlet and outlet ports. Cylindrical filters are attached to filter-heads fitted over openings in the end plates of the sections and the drum is partly filled with suitable granular scouring material. —W. H. C.

Reaction-tower. E. Hoefling. Ger. Pat. 272,608, July 29, 1913.

The tower is provided inside with projections arranged after the fashion of a spiral staircase.—A. S.

Liquefying gas mixtures and separating the constituents; Processes for ——. R. Mewes, Berlin. Eng. Pat. 9944, April 28, 1913.

See Fr. Pat. 456,027 of 1913; this J., 1913, 944.—T. F. B.

Filter press fabrics. F. E. Carman, Jamaica, N.Y., U.S.A. Eng. Pat. 11,538, May 17, 1913. Under Int. Conv., May 17, 1912.

See Fr. Pat. 457,953 of 1913; this J., 1913, 999.—T. F. B.

Distillation: Process and apparatus for continuous ——. F. Raschig, Ludwigshafen on Rhine, Germany. Eng. Pat. 14,230, June 19, 1913. Under Int. Conv., Oct. 26, 1912.

See Ger. Pat. 260,060 of 1912; this J., 1913, 692.—T. F. B.

Extraction apparatus; Cooler for ——. R. Oekel, Bonn, Germany. U.S. Pat. 1,095,165, April 28, 1914.

See Eng. Pat. 8110 of 1913; this J., 1914, 341.—T. F. B.

Furnace; Regenerator ——. Poetter Ges. m. b. H. Fr. Pat. 465,480, Nov. 29, 1913.

See Eng. Pat. 26,411 of 1913; this J., 1914, 408.—T. F. B.

Purifying, clarifying, deodorising, decolorising, and rendering electro-active solids, liquids, semi-liquids, and gases, also unctuous and hygroscopic substances; Process for ——. R. Marcus. Fr. Pat. 465,569, Dec. 1, 1913.

See Ger. Pat. 268,057 of 1912; this J., 1914, 188.—T. F. B.

Drying rooms. E. Rosenberg. Fr. Pat. 465,768, Dec. 5, 1913. Under Int. Conv., May 23, 1913.

See Eng. Pat. 12,070 of 1913; this J., 1913, 1147.—T. F. B.

Absorption, reaction, mixing, and cooling towers; Material for filling ——. Nitrogen Products and Carbide Co., Ltd., and H. Nielsen. Fr. Pat. 465,937, Dec. 9, 1913. Under Int. Conv., Nov. 15. 1913.

See Eng. Pat. 26,269 of 1913; this J., 1914, 241.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coke-ovens; Working —— in conjunction with blast-furnaces. H. J. Freyn. Scient. Amer. Suppl., 1914, **77**, 246—247.

The use of a mixture of coke-oven gas and blast-furnace gas for driving gas engines is suggested. A mixture of 1 part of coke-oven gas (500 B. Th. U.) and 15 parts of blast-furnace gas (100 B. Th. U.) would have a calorific value of 125 B. Th. U. per cb. ft., and the calorific value of the mixture could be kept constant automatically by means of recording calorimeters arranged to control electric circuits for working the gas throttle valves. When a blast-furnace was put out of operation, it might be used as a gas producer of the slagging type, burning small coke, raw coal and coke breeze, so as to produce a gas which would have the same calorific value as the suggested mixture.—A. T. L.

Combustion of gas; Partial and intermittent ——. E. E. Somermeier. J. Ind. Eng. Chem., 1914, **6**, 374—378.

Mixtures of air with hydrogen and with natural gas were ignited in different ways (electrically heated wire, spark from induction coil, gas flame) and under different conditions in regard to volume and pressure of the gaseous mixture. Variations in these conditions led to considerable differences in the results. For the same percentage of combustible constituent and the same method of ignition, more vigorous reactions were obtained in small than in large volumes of gas, but the absolute amount of gas burned was greater when larger volumes were used. In a previous paper (this J., 1914, 343), as a result of calculations, it was stated that mixtures containing more than 2 % of natural gas or 5·9 % of hydrogen are potentially explosive. The present experiments indicate that to produce a vigorous reaction, when using ordinary methods of ignition, only a small excess of hydrogen but a very large excess of natural gas or methane above the calculated amount is required. —A. S

Cholesterol in petroleum oils; Alleged occurrence of ——. W. Steinkopf and H. Winternitz. Chem.-Zeit., 1914, **38**, 613—614.

No cholesterol could be detected in the lævo-rotatory fractions of certain Java oils (this J., 1912, 631), and the fractions of higher b.pt. of two Java oils and an Argentine oil, which showed a pronounced lævo-rotation, were also found, by the digitonin test, to contain none. It is possible, however, that the optical activity was due to the presence of decomposition products of cholesterol.—C. A. M.

Alcohol Motor Fuel Committee. Times, May 21, 1914. [T.R.]

The Alcohol Motor Fuel Committee of the Imperial Motor Transport Council, which was appointed to consider the question of alcohol as a substitute for petrol, has issued a preliminary report, calling attention to the importance of rendering the British Empire independent of fuel supplies from foreign countries, and pointing out that crops from which alcohol could be obtained might be cultivated in many parts of the Empire.

Repeated use of lubricating oil after filtration. Fenno. *See* I.

Physiological characteristics of acetylene, with respect to its use in mining. Smith. *See* XIXb.

Patents.

Explosions in mines; Method or means for suppressing —— by the use of non-combustible dust. R. Cremer, Leeds. Eng. Pat. 1493, Jan. 20, 1914. Under Int. Conv., Jan. 20, 1913.

Non-combustible dust such as stone dust is formed into walls, banks, slabs, or columns, which are placed along the sides of mine roadways, etc. The dust may either be enclosed in wicker work, wire gauze, mill board or the like, or it may be formed into briquettes and bound with cement, concrete, tar, sizing, or clay. Coal dust can be swept from the surface of the slabs, etc., without waste of stone dust, and in the event of explosion the slabs are blown into the roadway and become broken up, thus increasing the non-combustible flame-cooling surface. —H. H.

Freeing smoke from soot and like material; Method and means for ——. K. Bombhard, Charlottenburg, Germany. Eng. Pat. 6123, March 12, 1913.

The smoke is passed through an enlarged flue so as to reduce its speed and allow soot to settle. The deposit is removed from the flue by a scraper conveyor which travels along the bottom in the same direction and at approximately the same speed as the smoke. The conveyor may be in the flue itself or in a compartment separated from the flue by a partition which extends from the roof to a point short of the floor of the flue, the latter being inclined towards the conveyor chamber. —W. H. C.

Coking processes and apparatus therefor. J. Moeller and H. C. Woltereck, London. Eng. Pat. 3375, Feb. 10,1913.

The retorts are arranged in pairs, one of each pair being charged with coal and the other with coke. They are heated to about 700° C. and superheated steam at 400° to 600° C. is introduced at low pressure into those containing coal. The mixture of hydrocarbon vapours and superheated steam produced is passed through the retorts containing coke which acts as a contact material decomposing the heavy oils into lighter hydrocarbons. The vapours are passed through a condenser and the uncondensed gases utilised for heating the retorts. The pipes and connections are so arranged that the process may be made continuous.—H. H.

Vertical retorts for use in the manufacture of gas. Drakes Ltd. and A. Dobson, Halifax, Yorks. Eng. Pat. 8524, April 11, 1913.

Heating flues for a secondary supply of air are arranged outside the combustion chambers surrounding the lower portions of vertical gas retorts. The air is led from the flues into the combustion chambers through vertical passages having dampers so arranged that the height at which the air enters the chambers can be varied.—H. H.

Retorts for use in the manufacture of gas for illuminating and heating purposes. S. L. Elborne, Peterborough, and H. Godsal, London. Eng. Pat. 9176, April 18, 1913.

Fireclay retorts are rendered impervious to gases by means of a clay such as China stone which becomes incipiently vitrified at the highest temperature of manufacture of the retort. The added clay may be incorporated with the fireclay, or it may form a layer not less than ¼ inch thick, either inside or outside the retort.—H. H.

Regenerative retort bench. R. B. Brown, Milwaukee, Wis., Assignor to Riter-Conley Manufacturing Co., Pittsburgh, Pa. U.S. Pat. 1,094,523, April 28, 1914.

The combustion chambers beneath a bench of retorts are provided with walls separate from the supporting walls of the bench itself so as to form additional flues or ducts between the combustion chamber and retort bench walls. Adjustable baffles are fitted in the flues.—H. H

Coal; Carbonisation of ——. V. B. Lewes, Greenwich. Eng. Pat. 9988, April 28, 1913.

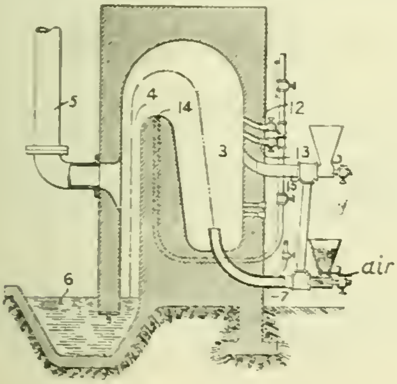
To obtain a large proportion of light hydrocarbon vapours, a minimum of heavy tar, and a uniformly carbonised residue containing sufficient volatile matter to form easily ignited smokeless briquettes, coal or shale is carbonised by radiant heat whilst falling, in a finely divided state, through the upper part of a vertical retort maintained at 1000°—1200° C. The heating gases pass downwards through flues around the retort, the lower part of which is at 400° C. The partially carbonised residue in the lower part of the retort is withdrawn continuously by a screw conveyor, the speed of which is adjusted so as to maintain the level of coke in the retort at the point at which distillation by radiant heat ceases.—A.T.L.

Gas. F. P. Peterson, Tulsa, Okla. U.S. Pat. 1,094,864, April 28, 1914.

THE easily liquefiable constituents of natural gas consisting mainly of ethane, propane, and butane, are substantially freed from methane, pentane, and higher paraffins, and the mixture liquefied.—H. H.

Gas-producer. J. H. Hirt, El Paso, Tex., Assignor to Allis-Chalmers Manufacturing Co. U.S. Pat. 1,094,897, April 28, 1914.

THE fuel is injected upwards from pipes, 7, 15, into a chamber, 3, which communicates with a passage, 4, dipping into a water seal, 6, and provided with a gas outlet 5.



Steam or moist air is introduced through pipes, 12, 13, 14, arranged in advance of the fuel inlets.—H. H

Gas; Process of making ——. H. Burgi, Springfield, Mass. U.S. Pat. 1,095,806, May 5, 1914.

COAL is passed continuously downwards through a vertical retort heated externally. Enriching hydrocarbons are admitted by a pipe extending through the upper part of the fuel column and delivering at a point where the temperature is suitable for cracking these hydrocarbons, and the gases produced at all parts of the retort are withdrawn from the cracking zone.—A. T. L.

Lighting gas; Manufacture of ——. Cie. Française du Centre et du Midi pour l'Eclairage au Gaz. Fr. Pat. 466,197, Feb. 24, 1913.

COAL is distilled in a closed retort and gases having respectively high candle-power and high calorific power are drawn off from separate outlets, the gas of high candle-power being formed when the charge of fresh coal first comes in contact with the hot walls of the retort. This gas is mixed with a suitable quantity of water-gas. The gas of high calorific power consists chiefly of methane, hydrogen and carbon monoxide; it is mixed with water-gas and passed over reduced nickel at 300° C., forming a gas containing 50 % methane. This gas may also be mixed with water-gas.—A. T. L.

Water-gas, oil-gas or both; Production of —— *in horizontal coal-gas retorts.* A. Le Morvan. Fr. Pat. 466,309, Feb. 27, 1913.

AN iron tube, pierced with holes throughout its length, is introduced into the centre of the mass of incandescent coke in the retort, and water or steam is forced through the tube. A second tube may be provided for injecting oil for making carburetted water-gas, or a single tube may be used, the steam passing through an injector nozzle so as to draw in oil.—A. T. L.

Water-gas; Manufacture of ——. Dellwik-Fleischer, Wassergas Ges. m. b. H. Fr. Pat. 466,421, Dec. 20, 1913. Under Int. Conv., Aug. 6, 1913.

IN making water-gas from bituminous coal, the air blast is introduced at an intermediate point of the height of the fuel column and passes downwards, the products escaping from the lower part of the producer. During the gas-making period, steam is blown upwards through the whole height of the fuel column. The water-gas formed in the lowest part of the fuel column thus passes through a zone of higher temperature and then through fuel which is not completely carbonised, becoming enriched with methane, tar, ammonia, benzene, etc.—A. T. L.

Gas; Manufacture of —— *from bituminous fuel.* Dellwik-Fleischer Wassergas Ges. m. b. H. Fr. Pat. 466,422, Dec. 20, 1913. Under Int. Conv., March 12, 1913.

THE producer is blown alternately with air and with steam and air. During the air-blow, air admitted above, and also at the middle of the height of the fuel column passes downwards to an outlet beneath the grate. When the fuel has been raised to a sufficiently high temperature, steam is blown in beneath the grate, and air or air and steam at a higher level where the production of water-gas ceases, the gas being drawn off from the top of the fuel column. —A. T. L.

Fuel wastes; Method of utilising ——. J. M. W. Kitchen, East Orange, N.J. U.S. Pat. 1,094,390, April 21, 1914.

FUEL from which tar and other volatilisable materials have been driven by heat is mixed with waste carbonaceous dust and converted into gaseous fuel in a gas producer. —H. H.

Gas washer. W. B. Osborne, Sewickley, Pa., Assignor to Riter-Conley Manufacturing Co., Pittsburgh, Pa. U.S. Pat. 1,094,466, April 28, 1914.

THE gas is passed vertically through a casing having a number of spraying nozzles adapted to project horizontal sprays of liquid alternately from opposite sides of the casing. Baffles are provided to direct the gas in a tortuous path.—H. H.

Gas-washer or scrubber. W. J. Fiddes, Tottenham. U.S. Pat. 1,095,835, May 5, 1914.

THE scrubber comprises a vertical cylindrical casing divided into a number of superposed compartments. An agitator, rotating on a central vertical shaft, comprises a series of horizontal plates in each compartment of the scrubber provided with inclined angle rings on both surfaces, the rings on the bottom of one plate projecting between those on the top of the next lower plate.—A. T. L.

Scrubbers for purification of gas. C. Heine. Fr. Pat. 466,349, Dec. 18, 1913.

THE gas is passed through a casing containing baffle-plates spaced apart from each other and from the wall of the casing, and arranged at an angle to the path of the gas. Water or other liquid or gaseous purifying agent is injected in the direction of flow of the gas so as to be thrown with the gas against the baffles, and water is also injected vertically downwards in order to counteract the tendency of the hot gases to circulate upwards. —A. T. L.

Hydrocarbons; Treatment of ——. J. Rosen, Paris. Eng Pat. 10,208, April 30, 1913.

Coal tar, petroleum residue or other hydrocarbon, is caused to flow through a series of cylindrical vessels provided with baffles, and a strong current of air is forced through the liquid in fine streams in the opposite direction. No external heat is used, but oxidation proceeds more rapidly and to a definite degree in each successive chamber. The oxidation may be started by cold air containing ozone or an added proportion of oxygen.—A. T. L.

Hydrocarbon residues; Process of and apparatus for distilling and cracking light ——. A. F. G. C. P. J. von Groeling, Vienna. Eng. Pat. 10,213, April 30, 1913.

The vapours from the still are passed through cracking tubes, which may be arranged in the furnace setting so as to be heated by the gases which heat the still, and thence through a dephlegmator. The crude oil flows to the still through the cracking tubes which contain spiral baffles to mix throughly the vapours from the still with the liquid flowing in the opposite direction to the still.
—A. T. L.

Liquid fuel for internal combustion engines; Method of treating —— and means therefor. G. E. Heyl and T. T. Baker, London. Eng. Pat. 11,756, May 20, 1913.

The liquid fuel is sprayed into an atmosphere of hydrogen at the ordinary temperature, and then passed through or over a catalytic agent consisting of aluminium or nickel powder in order "to promote the retention of the hydrogen."—W. H. C.

Hydrocarbon liquids; Increasing the [lighting and heating] efficiency of —— and material for effecting such results. A. W. Swanberg, Minneapolis, Min. U.S. Pat. 1,092,461, April 7, 1914.

Low-grade gasolene or naphtha is mixed per gall. with 1 oz. of a powder consisting of 7 parts of naphthalene and 3 parts of anthracene. To increase further the lighting or heating power, ½ oz. of sulphuric acid and ½ oz. of wood alcohol may be added.—A. T. L.

Petroleum; Process of and apparatus for distilling ——. J. W. Van Dyke and W. M. Irish, Assignors to The Atlantic Refining Co., Philadelphia, Pa. U.S. Pat. 1,095,438, May 5, 1914.

A three-way cock is provided in the pipe leading from the still to the condenser, and at the end of a run, the vapours remaining in the still are blown out by means of steam, through the cock and a branch pipe, so as not to contaminate the first runnings from the next charge.
—A. T. L.

Liquid fuel for internal-combustion engines; Manufacture of ——. J. Andrews. Fr. Pat. 466,050, Dec. 11, 1913.

Naphthalene (800—1000 parts) is mixed with kerosene (4 parts) and heated under pressure at 170°—180° F. (77°—82° C.) with a product obtained by distilling at 225°—230° F. (107°—110° C.) under a pressure of 60—70 lb. per sq. in., a mixture of sulphur, 1 part, concentrated ammonia, 8—10 parts, and water, 800—1000 parts. The naphthalene is converted into volatile oils which separate from the aqueous layer; the oily product is purified by treating with sulphur dioxide under pressure. Another process consists in heating 800 parts of naphthalene and 2 parts of kerosene with a solution of 1 part of nitre in water and 2 parts of concentrated ammonia, at 160°—180° F. (71°—82° C.) under pressure. The product distils at 180° to 300° F. (82°—149° C.) and has the sp. gr. 0·74.
—A. T. L.

Ovens for generating gas and producing coke. H. Koppers, Essen-Ruhr, Germany. Eng. Pat. 16,318, July 15, 1913.

See Fr. Pat. 460,517 of 1913; this J., 1914, 68.—T. F. B.

Lighting and heating gas and hydrogen; Process and apparatus for making —— by decomposing the vapours of oil, tar, or liquid hydrocarbons. Berlin-Anhaltische Maschinenbau-A.-G. Fr. Pat. 466,040, Dec. 10, 1913. Under Int. Conv., Jan. 27, 1913.

See Ger. Pat. 267,944 of 1913; this J., 1914, 190.—T. F. B.

Gas producers. A. Franks and G. Sanders. Fr. Pat. 466,199, Dec. 15, 1913. Under Int. Conv., Dec. 16, 1912.

See Eng. Pat. 28,936 of 1912; this J., 1914, 68.—T. F. B.

Generator gas; Purifier for ——. Berlin-Anhaltische Maschinenbau-A.-G. Fr. Pat. 465,472, Nov. 28, 1913. Under Int. Conv., Dec. 11, 1912.

See Ger. Pat. 271,112 of 1912; this J., 1914, 472.—T. F. B.

Fuel; Process of treating liquid —— to produce vapour. A. T. Porter, New York. Eng. Pat. 10,047, April 29, 1913.

See U.S. Pat. 1,064,086 of 1913; this J., 1913, 743.

Preventing deposition of carbon in reversing furnaces. U.S. Pat. 1,093,895. *Se* I.

Gas-analysis apparatus. U.S. Pat. 1,089,390. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood distillation under diminished pressure. A contribution to the problem of utilisation of wood waste. M. Adams and C. Hilton. J. Ind. Eng. Chem., 1914, **6**, 378—382.

The yield of oil of turpentine from a given sample of dry wood by destructive distillation was increased by 10—20 % by working under diminished pressure.—A. S.

Patent.

Process of treating wood with a view to its conversion into carburetted alcohol. Fr. Pat. 465,534. *See* XVIII.

III.—TAR AND TAR PRODUCTS.

Water-gas tar; Composition of ——. C. R. Downs and A. L. Dean. J. Ind. Eng. Chem., 1914, **6**, 366—370.

Tar obtained in the purification of carburetted water-gas was subjected to systematic fractional distillation, and the distillates and residue examined. The tar was practically free from bases, phenols and free carbon, and its hydrocarbon constituents were similar to those of ordinary coal tar, paraffins and naphthenes being present, at the most, only in small quantities. Benzene, toluene, xylenes, mesitylene, naphthalene, and anthracene could be prepared from the tar by methods similar to those used with coal tar.—A. S.

Benzene nitrating apparatus; Explosion of a cast iron ——. P. Pikos. Chem.-Zeit., 1914, **38**, 626—627.

Benzene (880 kilos.) had been run into a still containing sodium nitrate (920 kilos.) and sulphuric acid (1200 kilos.). The benzene had been run in too rapidly and had partially volatilised, and the excess of nitric acid had probably formed di- and trinitrobenzene, especially as the charged apparatus had been allowed to stand for two days. At the end of this period part of the contents had crystallised. Water was added, and the still, with all openings closed, was heated up again. On attempting to empty the contents, by compressed air, a violent explosion occurred. It is considered that the dilute acid, produced by the addition of water, reacted with the iron of the still, and reduced the nitrobenzene to β-phenylhydroxylamine and p-aminophenol, the latter being oxidised to azoxybenzene which decomposed explosively on heating.—G. W. McD.

o-Nitro-p-diazonium-phenol and the constitution of the "diazo-phenols." A. Klemenc. Ber., 1914, **47**, 1407—1416.

Of the three possible constitutional formulæ for the "diazo-phenols" the author prefers the diazonium type, $\mathrm{R}{<}^{\mathrm{O}}_{\mathrm{N:N}}$, on various grounds, of which the chief is the formation of o-nitro-p-diazonium-phenol on heating o-nitroanisole-p-diazonium chloride in acetic acid to 80° C. This compound is also formed on diazotising p-amino-o-nitroanisole at 70°—80° C. It crystallises in yellow leaflets which explode violently at 168° C. or when struck; when boiled with alcohol, it yields o-nitrophenol.—O. E. M.

Patents.

Benzol; Purification of waste sulphuric acid from the refining of ——. A. Gasser. Ger. Pat. 272,130, Oct. 24, 1912.

The acid is agitated vigorously by a current of warm compressed air, whereby the impurities become agglomerated and can be skimmed off from the surface of the acid. The compressed air used for cooling the brickwork of chamber-ovens or coke-ovens may be used for purifying the acid, when the manufacture of benzol is carried on at the same works as the manufacture of gas or coke.—A. S.

Pitch; Manufacture of ——. Deutsch-Luxemburgische Bergwerks- und Hütten A.-G. Ger. Pat. 272,189, April 2, 1913.

Tar is heated with the waste sulphuric acid obtained in the refining of benzol.—A. S.

Chloro-derivatives of the anthraquinone series; Manufacture of ——. A. G. Bloxam, London. From Act.-Ges. f. Anilinfabr., Treptow, Germany. Eng. Pat. 15,937, July 10, 1913.

See Fr. Pat. 460,432 of 1913; this J., 1914, 18.—T. F. B.

Nitro bodies; Purification of ——. O. Silberrad, Buckhurst Hill. U.S. Pat. 1,095,937, May 5, 1914.

IV.—COLOURING MATTERS AND DYES.

ndigo syntheses; New ——. W. Madelung. Annalen, 1914, **405**, 38—95.

A detailed description of the experimental investigations elating to the synthesis of indigo from di-indyl (from xaltoluide) and from indole, a brief account of the results f which has been given previously (this J., 1913, 972).—A. S.

yclic ketones [vat dyestuffs]; A new method for the preparation of ——. I. A. Schaarschmidt. Annalen, 1914, **405**, 95—127.

he method consists in the condensation of o-halogen-nzoquinone- or -anthraquinone-nitriles with amines to rm o-cyanoimines, and further condensation of the tter into acridone-derivatives. It may also be applied to the production of high molecular thioxanthones (see also Ger. Pat. 269,800; this J., 1914, 116). The preparation of a number of cyano-anthraquinone derivatives and of acridones therefrom is described. 1-Cyano-2-bromoanthraquinone and condensation products therefrom not containing a second anthraquinone residue in addition to the 1-cyanoanthraquinone nucleus give blue vats. Introduction of a second anthraquinone residue leads to the production of reddish-brown to red vats. These compounds have relatively slight affinity for vegetable fibres unless alkali salts are added to the bath. The trianthraquinonyl-cyano-derivatives, on the other hand, give intense dyeings from the vat without addition of salts. The anthraquinone-mono- and di-acridones obtained by further condensation from the cyano-imine derivatives are valuable vat dyestuffs giving shades of good fastness. The resistance to boiling soap solution can be increased by halogenation. The colours of the vats yielded by the acridones prepared and the shades they produce on cotton are shown in the following table:—

Compound.	Colour of vat.	Shade on cotton.
Acridone from 1-cyano-2-p-chlorophenylaminoanthraquinone	red	orange yellow
1-N-2-Anthracridone	violet blue	red
1.2.2'.1'-Dianthraquinoneacridone	blue violet	reddish orange
1.2.2'.3'-Dianthraquinoneacridone	red	orange yellow
Trianthraquinonediacridone from di-(1-cyano-2-anthraquinonyl-)-1'.5'-diaminoanthraquinone	violet blue	brownish red
Trianthraquinonediacridone from di-(1-cyano-2-anthraquinonyl-)-1'.8'-diaminoanthraquinone	violet blue	reddish brown
Trianthraquinonediacridone from di-(1-cyano-2-anthraquinonyl-)-1'.4'-diaminoanthraquinone	violet	violet blue
Anthraquinonemethylanthrapyridoneacridone	red	red

—A. S.

Lichens; British dye ——. A. Edge. J. Soc. Dyers and Col., 1914, **30**, 186—189.

Cudbear was formerly made in considerable quantities in Scotland, generally by the action of ammonia and air on *Lecanora tartarea* and *Urceolaria calcaria*; *Evernia prunastri*, *Umbilicaria vellea*, *U. pustulata*, *Parmelia perlata*, *Lecanora pallescens*, and some other lichens of less commercial value also give a purple colour by this method. The dyestuff made from these British lichens is not equal in brilliancy to that from the *Roccellae* (Orchil). In the case of the Crottles, which are still largely used for dyeing browns on the home-spuns of Harris, Lewis, Donegal, Shetland, etc., the dyestuff appears to be ready formed in the plant and is obtained by simple extraction. The best known are *Parmelia saxatelis* or Black Crottle and *P. omphalodes*, while others are *P. caperata* or Stone Crottle, *P. ceratophylla* or Dark Crottle, *P. parictina*, and a few species of *Sticta*, especially *S. pulmonaria* or Hazel Crottle. These lichens undergo no preparation, being gathered in July or August, when they are richest in colouring matter, and simply dried in the sun. They dye without addition to the bath and do not form lakes. Fine shades of brown are obtained, fast to acids and alkalis, but less fast to light than a mixture of Metachrome Brown B and Metachrome Orange 3R, although in fading an agreeable tone is maintained.—J. B.

Dyestuffs; Diffusion of some ——. R. O. Herzog and A Polotzky. Z. physik. Chem., 1914, **87**, 449—489.

The diffusion of a large number of dyestuffs into water from a 0·25 % aqueous solution and into a 5 % gelatin gel from a solution in 5 % gelatin was studied. The detailed results are tabulated.—A. S.

Patents.

Azo dyes; Manufacture of ——. Anilinfarben- und Extract-Fabr. vorm. J. R. Geigy, Basle, Switzerland. Eng. Pat. 26,908, Nov. 22, 1913. Under Int. Conv., Dec. 13, 1912. Addition to Eng. Pat. 25,866, Feb. 1, 1912.

See Eng. Pat. 8415 of 1913; this J., 1914, 414.—T. F. B.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Flax and hemp; Natural colouring matters of —— *and analytical characters of the raw and bleached fibres.* A. Bianchi and G. Malatesta. Annali Chim. Appl., 1914, 1, 281—291.

Unbleached flax and hemp when tested by the method of Green and others (this J., 1907, 1083) may give results indicating the presence of acid colours, and it is necessary always to apply confirmatory tests to the colour after it has been transferred to wool. Raw flax contains at least two colouring matters, one precipitated by basic lead acetate and the other not. The reddish-yellow aqueous solution of the former when treated with calcium hypochlorite solution is partially bleached in a short time and after some hours gives a yellow precipitate. The other colouring matter gives a clear yellow solution; on treatment with calcium hypochlorite the colour changes to pink after a short time and after some hours is completely bleached. Unbleached hemp also contains two colouring matters, one precipitated by basic lead acetate and the other not. The characters of the different kinds of raw and bleached flax are given as follows:—

	Ash.	Fat and wax.*	Aqueous extract.	Remarks.
	%	%	%	
Raw	0·6—1·2	1·3—2 or more	3—4	Contains notable quantities of natural colouring matter.
Washed	0·6—0·8	1·2—1·5	1—2	Little natural colouring matter.
Bleached	rather less than in "washed"		1—1·5	No colouring matter.
"Cream"	0·4—0·8	1—2	about 2	Characteristic reddish-yellow tint; yields chlorides to cold water.

* Extracted by carbon tetrachloride.

—A. S.

Casein for coated papers. E. Sutermeister. Paper Making, 1914, 33, 140—143; 187—190.

Casein is precipitated either by a mineral acid or by natural souring; hydrochloric acid gives quite a different product from sulphuric acid, and the natural curd differs from both; the rennet curd is not suitable for paper coating. For testing the solubility, 50 grms. of casein, ground to pass through a 20-mesh sieve are mixed with 200 c.c. of water and 7·5 grms. of borax; the mixture is heated on a water bath and stirred until the mixture becomes homogeneous. The temperature should not exceed 82° C. nor the time of stirring 10 minutes. Some samples of casein require slightly more borax, some show a small quantity of white flaky residue. For determining the strength of the casein a direct coating-test should be made:—50 grms. of casein are placed in a tared beaker with 190—200 c.c. of water and the necessary amount of borax to effect complete solution. When dissolved, the weight of the solution is made up to 250 grms. 100 grms. of fine clay, dried at 100° C., are ground with 70 c.c. of water in a separate vessel, the mixture is weighed, together with a copper spatula and 30 grms. of the casein solution (=6 grms. of casein to 100 of dry clay) are stirred in. A sheet of paper is evenly coated on a level surface with this mixture, using a curved steel scraper; th mixture is weighed again and more casein added to bring the proportion of casein up to 7 per 100 of clay. Succes sive coatings are thus made with various mixtures up t 11 % of casein. When all are dry, portions ar selected equally and evenly coated and short sticks o sealing-wax stuck vertically by melting upon the coate surface. These are pulled off, when cold, with a vertica pull and that proportion of casein is said to be stron enough which shows an even layer of paper fibres adherin to the coating pulled off on the end of the wax. Fo standardising this test it is necessary to work with standar samples both of clay and paper, large quantities bein stocked, since variations in the quality of these caus variations in the absolute results of the test. The pr portion of moisture in casein, on drying at 105° C., shoul not exceed 12·3 %.—J. F. B.

Analysis of the fatty substances of linen and hemp. Bianc and Malatesta. *See* XII.

Patents.

Cellulose; Preparation of pure ——. J. Daniel and F. Benoist. Fr. Pat. 465,471, Nov. 28, 1913. Under I Conv., Sept. 16, 1913.

Cellulose materials, *e.g.* raw cotton, are digested un a pressure of 1—4 atmos. with a liquid containing 2 %

sodium hydroxide, 1 of sodium carbonate, 1 of sodium sulphite and 0·1 of ethylene trichloride, for 4—12 hours. —J. F. B.

Cellulose acetates; Treatment of —— to modify their solubility in various solvents. V. J. A. Pauthonier. Fr. Pat. 466,009, Dec. 10, 1913.

The solubility of celluloso acetates is modified by partial hydrolysis by the action of water or a dilute acid. The treatment is liable to be irregular owing to the precipitation of a portion of the ester by the aqueous reagent. This irregularity is prevented by carrying out the hydrolysis by the addition of an anhydrous agent which is a solvent of the constituents of the mixture and which is capable of combining with the liberated acetic anhydride, while furnishing a hydroxyl group to produce the hydrolysis. Suitable agents are: acetone, phenol and chloral hydrate; when necessary, these may be diluted with glacial acetic acid.—J. F. B.

Cellulose; Manufacture of threads of hydrated ——. A. Pellerin. Fr. Pat. 466,292, Nov. 20, 1913.

Viscose solutions are squirted from a large number of fine orifices into a coagulating bath and the whole mass of threads so formed is drawn off by means of a drum, the speed of which can be accurately regulated. The drum may be used either as a winding drum or a guide roller. The mass of threads is cut up and treated by carding or drawing machinery as a sliver, being spun into yarn by the methods employed for textile fibres. The fineness, cross-section and lustre of the component filaments may be varied by varying the speed of the drum. —J. F. B.

Paper pulp; Manufacture of ——. F. L. Stewart. Fr. Pat. 465,732, Dec. 4, 1913.

The raw material is digested with an oxidising agent, *e.g.* dilute nitric acid, chromic acid or a mixture of dilute nitric and hydrochloric acids under a steam pressure of 4—5 atmos. for 10—30 mins., then drained, washed and neutralised with a 5—10 % solution of sodium hydroxide with which it is boiled for 5—30 mins. The pulp is bleached with ordinary bleach liquor which is gradually brought to the boiling point, a small quantity of dilute nitric acid being then added. The cellular matter of the plants is separated by this process from the fibres and may be collected for use as a filling material.—J. F. B.

Paper pulp; Treatment of ——. R. Marx. Fr. Pat. 466,334, Dec. 17, 1913. Under Int. Conv., May 2, 1913.

See Eng. Pat. 10,353 of 1913; this J., 1914, 20.—T. F. B.

Use of sulphite-cellulose extracts for the preparation of varnish. Fr. Pat. 466,196. *See* XIII.

Process of treating wood with a view to its conversion into carburetted alcohol. Fr. Pat. 465,534. *See* XVIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Dyeing [mordanting]; The theory of ——. III. W. D. Bancroft. J. Phys. Chem., 1914, **18**, 385—437.

A critical review of the literature on the theory of mordanting leads the author to conclude that there is no evidence of chemical union, but only of adsorption, the mordant, in the case of aluminium salts at any rate, consisting essentially of a colloidal solution of the metallic hydroxide. The difference between the behaviour of wool and of cotton is merely one of degree and would be expected from the "lesser adsorbing power of cotton."—J. B.

Hydroxy- and di-hydroxyanthraquinones; Physical-chemical examination of —— with special reference to their mordant-dyeing properties. G. F. Hüttig. Z. physik Chem., 1914, **87**, 129—168.

The values obtained for the dissociation constants indicate that the hydroxyl group is more strongly acid in the β- than in the α-position. In the following list the arrangement is in the order of increasing acidity: α-hydroxyanthraquinone, anthrarufin (αα), quinizarin (αα), chrysazin (αα), alizarin (α,β), β-hydroxyanthraquinone, anthraflavin (ββ) Monosodium alizarate is hence regarded as the β-salt. No relationship seems to exist between the mordant-dyeing property and the dissociation constant or the solubility. Concerning the nature of lakes the author regards actual salt-formation as the primary process, which may be followed by adsorption or other secondary processes.—J. B.

Prussian blue; Determination of —— in textile fibres. H. E. Williams and W. P. Dreaper. J. Soc. Dyers and Col., 1914, **30**, 191—192.

A reply to Farrel and Goldsmith's criticism of the authors' suggested substitution of the factor 2·18 for the conventional one of 1·5 for the conversion of the ferric oxide obtained by igniting the precipitated Prussian blue in the determination of Prussian blue in dyed and weighted silk (this J., 1912, 1076; J. Soc. Dyers and Col., 1913, 18). It is claimed that the suggested factor gives the real increase in weight of the cloth, which it is more important to know than the mere percentage of ferrocyanogen present. The suggested factor 0·01355 to be used instead of the usual factor 0·00955, when the estimation is carried out by distillation with cuprous chloride and acid is defended on the ground that the latter figure gives a result which is 30% below the actual weight of Prussian blue present on the fibre, owing to the large amount of water of hydration present in Prussian blue. This water varies under different conditions of formation of the blue but the suggested figure is based on experience and the possible error is not greater than the experimental error in the analysis.—J. B.

Copper on woollen cloth; A test for ——. A. Edge. J. Soc. Dyers and Col., 1914, **30**, 188—189.

Copper stains so faint as not to be detected by the ferrocyanide test, showed up on dyeing with dyestuffs sensitive to copper, *e.g.*, Acid Alizarin Violet N, Cyprus Green B, Diamond Green 3G. The cause of the stains was friction of the cloth on a brass part of the milling machine.—J. B.

Analysis of Turkey-red oil. Herbig. *See* XII.

Patents.

Silk-weighting; Process of removing tin from phosphate liquors used in ——. E. Meili, Hawthorn, N.J., Assignor to Weidmann Silk Dyeing Co., Paterson, N.J. U.S. Pat. 1,094,671, April 28, 1914.

Phosphate baths which have been used in the tin-phosphate method of weighting silk are regenerated by adding sodium silicate to the hot bath, the precipitated silicic acid carrying down with it the tin and other metallic impurities.—J. B.

Dyeing, bleaching, centrifuging, etc., textile materials; Apparatus for ——. W. Resch, Binningen, Switzerland. U.S. Pat. 1,095,028, April 28, 1914.

The casing of a hydro-extractor is connected with a circulating pump. The interior of the drum of the hydro-extractor is fitted with removable boxes having perforated ends which register in fluid-tight connection with the perforated portions of the walls of the drum. Means are provided for raising the drum so that its upper end engages in fluid-tight connection with the upper portion of the casing, whereupon liquid can be circulated by the pump through the boxes and casing in either direction. —J. B.

Amylaceous substances ; Process for rendering —— soluble. Maison Lepetit, Dollfus et Gansser. Fr. Pat. 466,275, May 29, 1913. Under Int. Conv., March 10, 1913.

PANCREAS or pancreas extract is used for converting starch or analogous substances into partially or completely soluble products, *e.g.*, in the manufacture of dressing or finishing preparations or for removing mucilaginous substances from fabrics.—L. E.

VII.—ACIDS ; ALKALIS ; SALTS ; NON-METALLIC ELEMENTS.

Ammonia ; Plant for the synthetic manufacture of ——. Chem. Zeit., April 23, 1914. [T.R.]

THE Badische Anilin und Soda Fabrik has decided to increase its capital by £900,000 to cover the cost of erecting plant for the synthetic production of ammonia by the Haber process. The works will be capable of producing eventually 130,000 tons of ammonium sulphate annually.

Arsenic in hydrochloric and sulphuric acids : Determination of ——. R. F. Tarbell. J. Ind. Eng. Chem., 1914, **6** 400—401.

IN the process described, the arsenic is converted into hydrogen arsenide which is passed through a solution of iodine in gasoline, whereby it is converted into arsenic tri-iodide Twenty-five grms. of the acid are treated with 35 grms. of zinc and 1 c.c. of stannous chloride solution (50 grms. Sn per litre). The sp. gr. of hydrochloric acid is first adjusted to about 1·1 and that of sulphuric acid to about 1·40 by addition of either water or arsenic-free acid. The reaction is allowed to proceed for about 2 hours, with warming if necessary, then 20 c.c. of sulphuric acid, of sp. gr. 1·4 are added, and the reaction allowed to continue for 1 hour more. The evolved gases are passed through a solution of lead acetate to remove hydrogen sulphide, and then through a bulb tube containing 80 c.c. of purified 60° gasoline, 20 c.c. of water, and 20 c.c. of a solution of iodine in purified gasoline (0·6773 grm. per litre). (The gasoline is purified by washing twice with sulphuric acid, then with dilute sodium hydroxide and with water.) The contents of the bulb tube are subsequently shaken with 200 c.c. of sodium arsenite solution (0·264 grm. arsenic trioxide, 1 grm. sodium carbonate, and 1 grm. sodium bicarbonate per litre), the aqueous layer removed and tho excess of arsenite titrated with iodine solution (0·6773 grm. iodine and 1·2 grms. potassium iodide per litre). The equations given are :—

$$AsH_3+3I_2=AsI_3+3HI\ ;$$
$$2AsI_3+3H_2O=As_2O_3+6HI\ ;$$
$$As_2O_3+2I_2+2H_2O=As_2O_5+4HI.$$

1 c.c. of the solution of iodine in gasoline is equivalent to 0·00005 grm. arsenic.—A. S.

Ammonia ; Conversion of —— into nitric acid or ammonium nitrate, from an economic standpoint. O. Dieffenbach. Chem. Ind., 1914, **37**, 265—269.

THE cost of converting ammonia into nitric acid and ammonium nitrate is compared with that of fixing it as ammonium sulphate, the relative cost of production, per unit of nitrogen, and the selling price being given for each. The computed values indicate that oxidation to nitric acid (even at its present price) is less remunerative than conversion into sulphate. But in factories producing calcium nitrate as a fertiliser from synthetic nitric acid. where the value of the nitrogen (per unit) in the dilute acid employed necessarily cannot be greater than that ir ammonium sulphate or Chili saltpetre, the absorption o ammonia by nitric acid is shown to be more economica than by sulphuric acid, and it is suggested tha the production of ammonia from calcium cyanamide o aluminium nitride should be combined with the manufacture of nitric acid by the Birkeland-Eyde process.
—F. SODN

Metallic sulphates ; Action of chloroform on ——. Metho of preparing anhydrous chlorides. A. Conduché. Compte rend., 1914, **158**, 1180—1182.

THE anhydrous metallic sulphate was placed in a boat i a tube and dried by a current of carbon dioxide. Chlor form vapour was then passed through the heated tub With copper sulphate sulphurous and sulphuric anhydrid and chlorides were formed at 250° C. Between 250° ar 300° C., the sulphate was completely transformed in cupric chloride. Above 400° C. cuprous chloride w formed. Other sulphates such as those of lead, magnesiu calcium, etc., decomposed at somewhat higher temper tures.—F. SHDN.

Hydrosulphite ; The action of hydrogen sulphide on sodi ——. F. S. Sinnatt. J. Soc. Dyers and Col., 19 **30**, 189—191.

HYDROGEN sulphide is without action on dry hyd sulphite but reacts rapidly in the presence of wat sulphur being precipitated in a granular form and th sulphate together with small amounts of sulphate a sulphite remaining in solution. The amounts of absorbed and of sulphur and thiosulphate produced agreed approximately with the equation: $Na_2S_2O_4+H_2S=Na_2S_2O_3+H_2O+S$, the hydrosulphite apparently acting as an oxidising agent. (See also Binz, this J., 1905, 800.) —J. B.

Magnesite discovery in South Australia. Board of Trade J., May 14, 1914. [T.R.]

An extensive deposit of high grade magnesite has been discovered near Tumby, on Eyre's Peninsula. It should be possible to deliver the crude magnesite at Port Adelaide for about 25s. per ton.

Magnesium in calcium salts; Method for the determination of ——. J. C. Hostetter. J. Ind. Eng. Chem., 1914, **6**, 392—396.

Specimens of a large number of calcium salts from both American and foreign manufacturers were found to contain considerably larger quantities of magnesium salts than stated by the makers. Small quantities of magnesium in calcium salts could not be determined accurately when the calcium was separated as oxalate or carbonate, even when the precipitation was repeated, as an appreciable quantity of magnesium was invariably retained by the precipitate. Satisfactory results were obtained by removing the calcium as sulphate but the method was too tedious for ordinary use. The author recommends a preliminary concentration of the magnesium as hydroxide in a precipitate containing but a small proportion of calcium, which can then be analysed accurately by the usual methods. Ten grms. of the calcium salt are dissolved in dilute hydrochloric acid, the solution boiled to expel carbon dioxide, sulphur dioxide or the like, neutralised with sodium hydroxide in presence of methyl orange, and the magnesium and a portion of the calcium precipitated as hydroxides by adding a quantity of calcium oxide equivalent to 0·3—0·5 grm. of calcium carbonate or by a suitable excess of sodium hydroxide. Calcium nitrate, acetate, formate or oxalate should first be ignited to oxide, of which a portion is reserved for effecting the precipitation, and the remainder dissolved in hydrochloric acid. The hydroxide precipitate is dissolved in dilute hydrochloric acid, the calcium removed by two successive precipitations as oxalate, and the magnesium in the filtrate precipitated as magnesium ammonium phosphate.—A. S.

Magnesium salts; Action of —— on complex compounds of aluminium, iron, and bismuth with organic substances. A. Quartaroli. Gaz. chim. ital., 1914, **44**, I., 418—443.

If a solution of a magnesium salt, containing sufficient ammonium chloride to prevent precipitation of the magnesium by ammonia, be added to a solution of chloride of iron or aluminium, and the whole treated with ammonia, a precipitate of a basic ferrite or aluminate containing per atom Fe up to 6 and per atom Al up to 5 atoms Mg, is produced. Also, iron, aluminium, and bismuth may be precipitated quantitatively by a suitable excess of a magnesium salt from solutions in which they are present in the form of complex ions with hydroxy-acids or polyhydric alcohols. In some cases basic ferrites and aluminates are precipitated as before; in others the precipitate also contains organic matter, probably owing to a molecular transformation of the complex salt into an ordinary basic salt: in the case of iron and aluminium this basic salt is capable of combining with magnesium, but with bismuth the precipitated basic salt is free from magnesium.—A. S.

Acids; Acid salts of dibasic ——. III. Oxalates. E. Jungfleisch and P. Landrieu. Comptes rend., 1914, **158**, 1306—1311.

It has already been shown that the acid salts of camphoric acid are compounds of the acid with the normal dimetallic camphorate, being analogous in composition to acid salts of monobasic acids (Comptes rend., 1913, **157**, 826; 1914, **58**, 445). It is now found that acid potassium oxalate has the corresponding composition, $K_2C_2O_4,H_2C_2O_4$, the alt being decomposed by water into the normal oxalate nd free acid.—L. E.

Ferric sulphates; The various normal, basic and acid ——. F. Wirth and B. Bakke. Z. anorg. Chem., 1914, **87**, 13—46.

Methods of preparing the different salts are indicated, as is also their behaviour towards water and steam. After hydrolysis the residue was always more basic in character than the solution. Dehydration occurred more and more readily with increasing acid nature of the salt: thus, ferric hydroxide itself could only be dehydrated at high temperatures. The isotherms of coquimbite, $Fe_2(SO_4)_3,9H_2O$, and ferric tetrasulphate, $Fe_2(SO_4)_3,H_2SO_4,8H_2O$, both for water and sulphuric acid at 25° C. are given. The existence of α- and β-copiapite, $3Fe_2O_3,8SO_3,27H_2O$ and $2Fe_2O_3,5SO_3,18H_2O$, respectively, was confirmed and quantitatively investigated. Ferric sulphate solutions dissolve ferric hydroxide giving strongly basic solutions, which, however, are acid to litmus; it is suggested that these solutions contain colloidal ferric hydroxide. The crystalline separations from solutions of differing acidity are also exhaustively described.—J. R.

Ferric sulphate and aluminium sulphate; Mutual solubility of ——. F. Wirth and B. Bakke. Z. anorg. Chem., 1914, **87**, 47—51.

At 25° C. no double salt could be caused to crystallise from solutions containing ferric and aluminium sulphates, neither could the formation of mixed crystals be established. Solutions containing more aluminium sulphate than is denoted by the relationship $Fe_2O_3:Al_2O_3=1:0{\cdot}3831$, deposited aluminium sulphate, in other cases ferric sulphate was deposited. At the same temperature the solubility of aluminium sulphate could be diminished by so much as 62·28 % through the addition of ferric sulphate, while the solubility of ferric sulphate could be diminished at the most by 29·04 % by addition of aluminium sulphate.—J. R.

Cobalt [and copper] oxides; Higher ——. A. Metzl. Z. anorg. Chem., 1914, 86, 358—368.

Iodine and sodium hydroxide gave with cobalt sulphate solution a black precipitate of cobalt peroxide, CoO_2, and the same oxide, mixed with metallic silver, was obtained by oxidising the cobalt solution with silver nitrate and caustic alkali. Hydrogen peroxide, in presence of sodium bicarbonate, gave an unstable olive green precipitate, of the composition, $CoCoO_3,CoCO_3$, and, under like conditions, copper sulphate was similarly oxidised, giving the compound $Cu_2CuO_4,CuCO_3$.—F. Sodn.

Copper peroxite [peroxide]. L. Moser. Z. anorg. Chem., 1914, **86**, 380—388. (Compare this J., 1907, 687.)

Pure copper peroxite, CuO_2,H_2O, was prepared by the action of hydrogen peroxide, at a low temperature, on an alcoholic solution of cupric chloride, containing potassium hydroxide, or on copper hydroxide suspended in alcohol; also by acting on finely divided copper hydroxide with an ethereal solution of hydrogen peroxide, at about 0° C. The dry peroxide decomposed explosively on warming; it gave almost the calculated quantity of hydrogen peroxide when treated with very dilute acids at about 0° C.—F. Sodn.

Lead oxides; Determination of the higher ——. I. Iodometric method. J. Milbauer and B. Pivnicka. Z. anal. Chem., 1914, **53**, 345—359.

Diehl's original iodometric method of determining the higher oxides of lead (Z. anal. Chem., 1907, **46**, 64) shows several sources of error. The following modification gave the best results: A weighed quantity of the oxide (0·5 grm. of red lead or 0·2 grm. of lead dioxide) was added to a well-cooled solution of 5 grms. of sodium acetate aod 0·5 grm. of potassium iodide in a mixture of 100 c.c. of water and 5 c.c. of glacial acetic acid. The iodine liberated was titrated as rapidly as possible with $N/100$-sodium thiosulphate solution. Slowness in titration and rise of temperature are sources of error. The change in iodine-value of thiosulphate solutions on keeping was also investigated. $N/10$-solutions showed relatively small changes, and constant values were attained only after about a week: but in the case of $N/100$-solutions the change occurred over much longer periods and in some cases the iodine-value fell to 50 % of the original. Dilute thiosulphate solutions should thus be frequently standardised.—J. R.

Ceric oxide; Products of the incomplete reduction of ——. A. Damiens. Bull. Soc. Chim., 1914, **15**, 372—375.

STERBA (Comptes rend., 1902, **136**, 1056) claimed to have obtained an oxycarbide of cerium, $CeC_2.2CeO_2$, by the reduction of cerium dioxide with a limited quantity of carbon. The author studied the action of progressively increasing quantities of carbon on cerium dioxide, and found that reduction proceeds in three stages:

$$2CeO_2+C=Ce_2O_3+CO;$$
$$Ce_2O_3+9C=2CeC_3+3CO;$$
$$CeC_3=CeC_2+C.$$

In all cases the product contained red crystals, probably mixed crystals of CeC_3 and fused cerous oxide, which were only slowly attacked by water and yielded solely acetylene hydrocarbons (completely absorbed by an alkaline solution of potassium and mercuric iodides) on treatment with acid.—A. S.

Beryllium; Oxalate and acetate of ——. F. Wirth. Z. anorg. Chem., 1914, **87**, 7—8.

AT 25° C. 100 c.c. of water dissolves 63·2 grms. of beryllium oxalate, $BeC_2O_4.3H_2O$, while 100 grms. of $N/10$-sulphuric acid dissolves 72·65 grms. and 100 grms. of $N/10$-oxalic acid dissolves 75·92 grms. of the same salt. The increased solubility in presence of free oxalic acid is attributed to the formation of beryllium-oxalic acid, $Be(C_2O_4H)_2$. The basic acetate, $Be_4O(CH_3COO)_6$, dissolves slowly when shaken with water at 40° C. and is thereby decomposed. 100 grms. of chloroform dissolves 33·3 grms. of the basic acetate at 18° C. and the resulting solution is very stable towards reagents.—J. R.

Scandium; Sulphate and oxalate of ——. F. Wirth. Z. anorg. Chem., 1914, **87**, 9—12.

AT 25° C. the pentahydrate, $Sc_2(SO_4)_3,5H_2O$, is stable, but somewhat above 100° C. this salt is converted into the dihydrate. At 25° C. 100 c.c. of water dissolves 54·61 grms. of the pentahydrate, which is thus the most soluble of the sulphates of the rare-earth metals. The solubility falls considerably in the presence of small amounts of sulphuric acid. The crystalline, hydrated oxalate, $Sc_2(C_2O_4)_3,5H_2O$, is most conveniently obtained by the addition of hydrochloric acid to its hot saturated solution in ammonium oxalate. In dilute sulphuric acid it is the least soluble of the oxalates of the rare-earth metals.—J. R.

Scandium; Alkali double oxalates of ——; *scandium-sulphuric acid and scandium sulphide.* F. Wirth. Z. anorg. Chem., 1914, **87**, 1—6.

SCANDIUM oxalate is readily soluble in hot solutions of alkali oxalates or ammonium oxalate, and the corresponding double oxalates separate on cooling. These substances possess the general formula, $Sc_2(C_2O_4)_3.3R_2C_2O_4,10H_2O$, and may be regarded as the alkali salts of a complex scandium-oxalic acid, $[Sc(C_2O_4)_3]H_3$. They are nearly insoluble in cold water and in cold solutions of alkali oxalates. The ammonium double salt is soluble in saturated ammonium oxalate solution. The scandium was determined by precipitation with ammonia from the solution of the ignited salt in dilute hydrochloric acid. Scandium hydroxide is somewhat soluble in potassium hydroxide solution, and hydrogen peroxide precipitates scandium peroxide from the solution thus obtained. Hydrochloric acid added to the hot solution of the double oxalates causes the separation of scandium oxalate, $Sc_2(C_2O_4)_3,5H_2O$. Scandium sulphate dissolves at ordinary temperatures in sulphuric acid of sp. gr. 1·6, and, upon keeping, scandium-sulphuric acid separates as white crystals of the composition, $Sc_2(SO_4)_3.3H_2SO_4$ or $[Sc(SO_4)_3]H_3$. Scandium sulphide, Sc_2S_3, is a light-yellow substance obtained by heating the sulphate in a current of hydrogen sulphide.—J. R.

Scandium; Contribution to the knowledge of ——. J. Sterba. Z. Elektrochem., 1914, **20**, 289—295.

SCANDIUM was isolated from wolframite residues by dissolving the oxides in hydrochloric acid and precipitating with ammonium fluoride. To separate pure scandium salt from this precipitate, lead, copper, etc., were precipitated with hydrogen sulphide from acid solution of scandium chloride; iron and manganese from solutions of the double scandium potassium carbonate, the former with potassium hydrogen sulphide and the latter with iodine in potassium iodide solution; molybdenum was removed as sulphide by precipitation in presence of formic acid; and thorium, yttrium and ytterbium by the precipitation of the double scandiam sodium carbonate, combined with the fractional crystallisation of scandium formate. A specroscopically pure scandium oxide was thus obtained. The observation of J. R. Meyer that scandium forms complex water-soluble fluorides was confirmed, and based upon this, a simple and complete separation of scandium from the other rare earths was devised.—G. F. M.

Nitrogen peroxide; Rate of dissociation of ——. W. L. Argo. J. Phys. Chem., 1914, **18**, 438—450.

EXPERIMENTS were made to determine if any appreciable time is required to establish equilibrium between NO_2 and N_2O_4 in nitrogen peroxide gas after an alteration of pressure. The oscillations of stationary sound waves were used to create very rapid changes of pressure. It was found that there was no appreciable lag in the re-establishment of the equilibrium, this being true for the dry gas and for gas containing 0·32 % by vol. of water vapour.
—J. B.

Hydrogen peroxide and sodium perborate; Decomposition of ——, *in alkaline solutions.* R. Schenck, F. Vorländer and W. Dux. Z. angew. Chem., 1914, **27**, 291—296.

DETERMINATIONS of the stability of hydrogen peroxide in alkaline solutions showed the velocity of decomposition to be dependent upon the concentration of the hydroxyl ion. The stability was increased, however, by the addition of sodium pyrophosphate, in spite of the alkaline reaction of solutions of that substance. This result is attributed to the formation of a perpyrophosphate, $Na_2P_2O_7,2\frac{1}{2}H_2O_2$, which is perfectly stable when isolated. Sodium pyrophosphate exerted a similar protective influence upon solutions of sodium perborate, in which the following equilibrium is regarded as existing:— $4NaBO_3+5H_2O\rightleftarrows Na_2B_4O_7+2NaOH+4H_2O_2$. In agreement with this, solutions of hydrogen peroxide were preserved by the addition of equivalent amounts of borax and sodium hydroxide. In both cases the protective action is inhibited by the addition of very small amounts of free alkali.—J. R.

Heavy chemicals in the United States. Oil, Paint, and Dru Rep., May 11, 1914. [T.R.]

IMPORTS of bleaching powder into the United States i 1913 amounted to 30,800 short tons, compared wit 37,120 tons in 1912, 41,450 tons in 1911, 50,500 ton in 1910, 45,700 tons in 1909, and 56,600 tons in 190 Imports from England have decreased from abou 30,000 tons in 1911 to 22,250 tons in 1913, whilst German supplies about 6000 tons annually. The output b American works amounts to about 90,000 tons, of whic about 30,000 tons is exported.

The output of caustic soda in 1913 reached about 190,0 tons, of which about 20,000 tons was exported. Th exports to Canada average 15,000 to 20,000 drums a yea

Arsenic was imported to the extent of 4130 tons in 191 which decreased to 3340 tons in 1913. Imports fro Europe have practically ceased, the only material source foreign supply being Canada. The output last year in t United States was 2375 tons, and in 1912, 3141 tons.

Volumetric determination of free sulphurous acid. Kedesdy. *See* XXIII.

PATENTS.

Sulphuric acid; Leaden chambers for use in the manufacture of ——. A. Nemes, Brussels. Eng. Pat. 24,223, Oct. 25, 1913.

A FRAMEWORK of flat and angle-iron bars, rigidly joined together, carries the bottom or tray of the chamber, and is secured to the iron uprights, which support the walls of the chamber, and which are suspended from the roof of the shed enclosing the chamber. The uprights, which are of circular section, are flattened at intervals, and the parts thus deformed are embraced by lead bands, which are "soldered" to the walls of the lead chamber and hold the latter in position. Collars, secured by pins, may replace the flattened projections on the uprights, the fastening bands in that case resting upon the collars. The bottom of the chamber rests on a wooden floor, which enables leakages of acid to be readily detected.—O. R.

Ammonia; Manufacture of —— from nitrogen and hydrogen. N. Caro. Ger. Pat. 272,638, Oct. 14, 1910.

A MIXTURE of soda-lime, potash-lime, or the like with titanium or vanadium, or both, is used as catalyst in the synthesis of ammonia from nitrogen and hydrogen under pressure at a high temperature. The catalyst is less sensitive than metals of the iron group to contact poisons, so that commercial hydrogen, obtained, for example, by the decomposition of hydrocarbons, can be used in the process.—A. S.

Cyanamide-producing apparatus. V. M. Weaver, Harrisburg, Pa. U.S. Pat. 1,093,749, April 21, 1914.

THE reaction chamber contains inclined grate bars which can be constantly agitated, and an adjacent heating plate with imbedded gas-heating pipe; the plate is heated by a burner beneath. Calcium carbide is fed continuously over the plate and bars and nitrogen forced upwards through the bars, which are perforated. The imbedded gas-heating pipe may receive nitrogen from an external source or gas from the heating zone for re-circulation. —F. SODN.

Nitrogenous compounds; Process of making ——. T. B. Allen, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,093,819, April 21, 1914.

SILICON carbide and a metal, *e.g.*, iron, are heated together in contact with substantially pure nitrogen.—F. SODN.

Metallic bodies; Method for the protection of —— agains the action of nitrous fumes. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Fr. Pat. 465,739, Dec. 4, 1913.

To protect them against the action of nitrous fumes, metallic surfaces are supplied with a sufficient quantity of water, which is allowed to flow in a thin layer over them. It is not necessary to use alkaline solutions, since the thin film of metallic oxide formed, effects the required protection.—T. ST.

Litharge; Process and installation for the manufacture of ——. E. Barthelmess. Fr. Pat. 466,129, Dec. 13, 1913.

A PEAR-SHAPED oxidation chamber, mounted in an inclined position, communicates at its lower wide end with a melting pot for lead, the whole being enclosed in the masonry of a furnace and heated externally by the furnace gases. A central rotating shaft passes longitudinally through the oxidation chamber and carries scrapers which remove deposits from the wall of the same, and also, at its lower end, a centrifugal wheel which dips into the melting pot and pulverises the molten lead, and, at the same time, acts as a fan, drawing in air or other gas containing oxygen and creating an upward draught through the oxidation chamber, so that the finely divided litharge produced by oxidation of the lead is discharged at the upper end, whence it is carried by a conveyor to collecting vessels. The gas is returned to the oxidation chamber after passing through heating flues in the masonry of the furnace. A regulated quantity of water is introduced into the current of gas just before it is drawn into the oxidation chamber by the fan.—A. S.

VIII.—GLASS; CERAMICS.

Zirconium dioxide; Production of fireproof articles from ——. O. Ruff, H. Seiferheld, and O. Bruschke. Z. anorg. Chem., 1914, **86**, 389—400. (See this J., 1913, 866.)

CRUCIBLES prepared from zirconium dioxide (mixed preferably with 1% of dry starch and 3% of magnesia), and fired first at 1450° C. and then at 2200° C., were found to be almost impervious and to resist a temperature of over 2200° C. in the vacuum electric furnace. They were successfully employed in determining the boiling point of pure iron, etc. and for fusing tungsten alloys. —F. SODN.

Patents.

Furnace-slag ; Process for obtaining from —— a material similar to ordinary pottery or the like. M. Chiapponi, Paris. Eng. Pat. 24,141, Oct. 24, 1913. Under Int. Conv., March 3, 1913.

See Fr. Pat. 455,381 of 1913 ; this J., 1913, 945.—T. F. B.

Enamel on sheet iron ; Process for preparing an ——. L. Honigmann. Fr. Pat. 465,574, Dec. 1, 1913. Under Int. Conv., April 4, 1913.

See Eng. Pat. 28,398 of 1913 ; this J., 1914, 355.—T. F. B.

Retorts for use in the manufacture of gas for illuminating and heating purposes. Eng. Pat. 9176. *See* IIa.

IX.—BUILDING MATERIALS.

Patents.

Waterproofing and colouring bricks, tiles, earthenware and the like. H. A. H. Moore, London. Eng. Pat. 10,493, May 5, 1913.

Bricks and the like are wholly or partially immersed in a bath, heated to about 300° F. (149° C.), of white refined paraffin wax, to which a quantity of fine clear rosin is added prior to the addition of aniline dye or other colouring medium.—B. N.

Concrete blocks or articles ; Induration of ——. J. S. Rigby, Liverpool. Eng. Pat. 11,498, May 17, 1913.

Induration of concrete is effected by steam supersaturated with moisture. In or on the floor of a closed chamber containing the concrete blocks or articles is a number of boxes filled with pumice-stone or like material, and to which water is supplied. The steam is passed through these boxes and thus becomes supersaturated with moisture.—O. R.

Cementitious product and process of making same. Process of making a cementitious composition. W. E. Carson, Riverton, Va. U.S. Pats. 1,094,876 and 1,095,180, April 28, 1914.

(1). An intimate, finely ground mixture of highly aluminous slag and quicklime is partially hydrated, so as to form compounds capable of setting on the further addition of water. (2.) Quicklime is added to clay, which has been pugged with just sufficient water to slake the lime and yield a dry product, the mixture being then roasted below the sintering point, say at 600°—800° F. (315°—426° C.). —O. R.

Fibrous material [silicon oxycarbide] and process of making the same ; Refractory ——. E. Weintraub and F. A. Kroner, Lynn, Mass., Assignors to General Electric Co. U.S. Pat. 1,094,352, April 21, 1914.

A mixture of silicon, or material yielding it, and a catalyst (*e.g.*, calcium fluoride) is heated (preferably to 1300°—1400° C.) in a space enclosed, at least partially, by a porous wall through which oxides or other gaseous compounds of carbon are allowed to diffuse.—F. Sodn.

Drying of wood and other substances. E. Wiart, Suresnes, France. Eng. Pat. 10,198, April 30, 1913.

See Fr. Pat. 449,913 of 1912 ; this J., 1913, 476.—T. F. B.

Roof coverings ; Manufacture of ——. A. Maschke, Brussels. Eng. Pat. 1155, Jan. 15, 1914. Under Int. Conv., Jan. 20, 1913.

See Ger. Pat. 264,407 of 1913 ; this J., 1914, 138.—T. F. B.

Artificial stone from natural-rock waste ; Process for the production of ——. W. Laufer, Cracow, Austria-Hungary. U.S. Pat. 1,094,727, April 28, 1914.

See Eng. Pat. 18,883 of 1912 ; this J., 1913, 290.—T. F. B.

X.—METALS ; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Slag ; Utilisation of the waste heat of ——. Times, May 21, 1914. [T.R.]

Much has been done in the last few decades to utilise the heat in iron blast-furnace slags, the annual production of which amounts to close on 200,000,000 tons. If their temperature is taken at 1500° C. the quantity of heat they contain must be enormous, all of which is wasted.

Efforts were made some years ago by the late Sir Lowthian Bell to save this heat, but the state of engineering achievement in his time did not permit a satisfactory solution of the problem. Further experiments have been in progress at the Clarence Works of Messrs. Bell Brothers, Middlesbrough, for some four years, the patents being in the hands of the Slag Power Company. The first plan was to drop the molten slag as it comes from the blast furnaces into water, and use the steam thus produced in a low-pressure turbine. But the considerable quantities of hydrogen and sulphuretted hydrogen produced along with the steam gave rise to difficulties in connection with obtaining the high vacuum necessary to the efficient working of the turbine. These difficulties were overcome, but a quantity of fine sulphur was also produced, and this it was found impossible to eliminate from the steam. Yet if it had not been removed it would have damaged the blades of the turbine with which it came into contact, and would also have blocked the steam passages. Another difficulty was caused by the fact that the hot blast-furnace slag when thrown into water froths up into a foam-like substance, which floats, and means had to be devised for submerging it and for removing it from the water.

Instead of attempting to use directly in the turbine the dirty steam generated by the contact of the slag with the water, the plan finally adopted was to employ it indirectly for generating clean steam by means of a heat exchanger, the particular form adopted being a Kestner single-effect climbing film evaporator. The hot slag is run direct from the blast furnace into the primary generator, in which an upright shaft with four blades revolves, keeping the water in constant rotation. When the slag drops through the orifice the velocity of its fall carries it well below the lip, and before it rises to the surface it is swept by the moving water past the orifice and inside the seal. An elevator then lifts it from the generator and drops it through a second seal ; by this time it is waterlogged and sinks, and it is then collected by a second elevator, which drops it into railway trucks for removal. The dirty steam passes from the generator to the evaporator, where it is used to produce clean steam, which is employed in the turbine. In the case of copper slag the second elevato is not required, since the slag does not float in water bu immediately sinks.

Over 740 kilos. of water have been evaporated pe 1000 kilos. of blast-furnace slag containing 550,00 calories ; deducting 18,000 calories removed with th slag at 100° C. and 42,000 removed with the water take up by the slag (on the assumption that it absorbs 50 % o water), the available heat is 490,000 calories, or, if a allowance of 25% is made for loss, 367,500 calories, whic divided by 622 give 590 kilos. of steam. As the result o many experiments the average efficiency of the evaporato is found to be 91%, but taking it at only 80% the amoun of clean steam available for the turbine is 472 kilos., an this with a consumption of 13 kilos. of steam per hors power, which is an excess of that guaranteed by th makers of the turbine with a vacuum of 28·5 in. and vacuum of 7 in. over the water in the evaporator, mean a yield of over 36 h.p. per 1000 kilos. of slag. Copper sla contains less heat than blast furnace slag, the amou being found by experiment to be from 318 to 350 calori per kilo., and therefore by a similar calculation 1000 kilo will produce 281 kilos. of clean steam, equivalent to yield of, say, 21 h.p. in the turbine.

It is estimated that with a 1000-kw. plant with 75 load the cost of generating 1 kw. would be 0·32d., where with a high-pressure steam plant using coal at 14s. 6d. ton it would be 0·48d., the economy realised by the a of the heat from the slag being thus 0·16d. per kw., whi under the conditions stated would amount to £4,300 a year. It is stated that the upkeep of the generator and evaporator is small. As the slag goes directly into the water, only steam at 100° C. comes in contact with the plant, which is thus not subjected to any great differences of temperature, while experience indicates that there is no action from the gases on the plates or tubes of the evaporator, provided they are kept clean.

Manganese ore deposit in Minnesota. Board of Trade J., May 14, 1914. [T.R.]

An extensive deposit of very high grade manganese ore has been discovered on the Cayuna Range, in the northern part of Minnesota.

Sheet iron for roofing ; Nature of the protective oxidised coating of ——. Matweeff. Rev. Mét., 1914, **11**, 480—482.

The protective coating of roofing (Russian) iron, although consisting mainly of the magnetic oxide, also contains ferrous oxide, present in a compact state in contact with the metal and forming a kind of skeleton in which the protective but porous and friable magnetic oxide is held. —W. E. F. P.

[*Steel*]. *Crucible v. electric furnaces.* C. T. Nesbitt. Chem. World, 1914, **3**, 131—132.

With electric power costing 0·66d. per kilowatt-hour (the price in Sheffield), the melting costs for the production of steel in crucible and electric furnaces are about the same—£2 10s. per ton. The electric furnace has the advantage as regards output, which more than balances the higher initial cost. It has also an immense advantage in that the commonest scrap or pig iron can be converted into steel equal to the best crucible-made product, and of any desired carbon content, with certainty and without trouble. The labour costs of the two processes are about the same.—T. St.

Iron, steel and nickel ; Relation between the variations of magnetism and electrical resistance of —— at high temperatures. K. Honda. Rev. Mét., 1914, **11**, 483—488.

Determinations were made with pure nickel (up to 800° C.), pure iron (up to 900°—1000° C.) and steels containing respectively C 0·64 and 1·30% (up to 900° C.) In each of the temperature-resistance curves a break occurred at the temperature corresponding to the disappearance of ferromagnetism. The variations of resistance between 100° and 200° C. corresponding to magnetic alteration in steels were very slight. The results confirm the view that the magnetic transformation is not an allotropic change but only a progressive alteration, with temperature, of the property of one phase. (See also this J., 1914, 83.)—W. E. F. P.

Titanium-iron alloys. J. Lamort. Ferrum, 1914, **11**, 225—234.

Alloys with Ti up to 24 %. were examined by the method of thermal analysis and microscopically. Three constituents were observed, viz., a solid solution of titanium in iron, an eutectic (Ti 13·2 %, m. pt. 1298° C.), present in alloys with Ti 6·3—19·9 %, and crystals, probably of Fe_3Ti (Ti 22·31 %). The temperature of the magnetic transformation point was lowered in direct proportion to the titanium content, being 690° C. for Ti 21 %. In Brinell tests with a load of 500 kilos., he hardness rose from 96 for pure iron to 484 with Ti 1·5 % ; with a load of 1000 kilos. alloys with Ti over 5 % fractured Commercial samples of ferro-titanium ree from carbon contained practically no titanium itride. The titanium content varied considerably n different parts of large pieces. In ferro-titanium ntaining carbon the titanium was present in some ases wholly as metal and in others wholly as nitride, nd this is probably the cause of the contradictory reports to the effect of titanium on the properties of iron nd steel. The addition of the same brand of ferro-itanium might in two cases yield different results according to the conditions of temperature, etc., as affecting the possible formation of nitride. In making the analyses the samples were treated with hydrochloric acid in a current of carbon dioxide, when the nitride remained undissolved. The dissolved titanium was titrated with a standard solution of ferric chloride with ammonium thiocyanate as indicator. The residue was ignited to oxide, and silica removed by means of hydrofluoric acid. —T. St

Iron ; Effect of addition agents in the electro-deposition of ——. O. P. Watts and N. H. Li. Met. and Chem. Eng., 1914, 12, 343.

The use of a pure chloride electrolyte is not practicable, but the admixture of some ferrous chloride with a sulphate solution improves the smoothness of the deposit ; but more satisfactory deposits are obtained by the addition of ammonium oxalate or formin (hexamethylenetetramine). —B. N.

Platinum (and iridium). A. Hänig. Oesterr. Zeits. Berg- u. Hüttenw., 1914, **62**, 203—204.

The estimated total production of platinum metal from the Urals is given as : 1907, 310,000 ; 1908, 250,000 ; 1909, 264,000 ; 1910, 275,000, and 1911, 300,000 oz. troy. The world's annual production of iridium probably does not exceed 5000 oz., most of which is used in the form of platinum alloys ; those with less than 10% Ir are ductile and malleable ; with 10—20 %, hard and difficult to work. In 1911 it was valued at £12 13s. per oz. Reference is made to the possibility of considerable quantities of platinum being produced, in the near future, at a mine in Wenden, Westphalia. —W. R. S.

Mercury recovery plant at Fresnillo. C. Robinson. Eng. and Min. J., 1914, **97**, 953—954.

Old "Patro" tailings (containing mercury) are treated by hyposulphite leaching for the recovery of silver in one department of the plant of the Fresnillo Co., Zacatecas, Mexico. The silver sulphide precipitated from the solution contains 200—300 grms. of mercury per ton, and the metal is recovered in a roasting furnace, which has a distilling hearth composed of fireclay tiles resting on a concrete foundation, from which it is separated by an iron plate, to stop leakage. The vapours pass from the furnace through a flue to four lines of condensing tubes, constructed of vitrified tiles cooled by water sprays. The open ends of the condensing tubes are sealed by water in a tank with inclined bottom and well for collection at the lower end.—O. R.

Lead [in ores] ; Volumetric method for the determination of ——. A. Alder and M. F. Coolbaugh. J. Ind. Eng. Chem., 1914, **6**, 398—400.

From 0·5 to 1 grm. of ore is treated with nitric acid and if necessary, with a small quantity of hydrochloric acid, and evaporated with a few c.c. of concentrated sulphuric acid. The residue is treated with 100 c.c. of water, boiled vigorously, 10—15 c.c. of alcohol added, and the lead sulphate filtered off, washed with a mixture of 1 % sulphuric acid and 10 % alcohol and then with alcohol, and dissolved in 10—15 c.c. of a hot 10 % solution of sodium hydroxide, the filter being washed successively with hot water, hot water acidulated with nitric acid, and water containing a little sodium hydroxide. The solution is treated with a few drops of phenolphthalein and a slight excess of potassium iodate, heated, and a slight excess (15—29 drops) of nitric acid of sp. gr. 1·2 added. The whole is heated to boiling, cooled slightly, treated with 15—20 c.c. of alcohol, cooled, filtered, and the filter washed with dilute alcohol (1 : 3) until the wash water gives no test for iodate when treated with hydrochloric acid, ammonium thiocyanate, and chloroform. The filter and precipitate are transferred to a flask, treated with 40—50 c.c. of dilute hydrochloric acid (1 : 2·5) and 3—5 c.c. of chloroform, and titrated with ammonium thiocyanate solution (2·5 grms. per litre until the chloroform is coloured violet. With ores rich in lead, 10—15 c.c. of hydrochloric acid of sp. gr. 1·1 should be added before the end point is reached. The equations given are:

$$3Pb(IO_3)_2+4NH_4CNS+16HCl=$$
$$6ICl+3PbCl_2+4NH_4Cl+4H_2SO_4+4HCN+2H_2O;$$
$$6ICl+NH_4CNS+4H_2O=$$
$$6I+NH_4Cl+H_2SO_4+5HCl+HCN.$$—A. S.

Zinc in its ores; Rapid determination of ——. Direct application of Frary's method to the analysis of ores. S. Zublena. Annali Chim. Appl., 1914, 1, 302—313.

From 2 to 5 grms. of the ore are evaporated with 30 c.c. of concentrated sulphuric acid and a small quantity of hydrofluoric acid, then diluted with water, the insoluble sulphates filtered off, and the solution diluted until it contains 25—30% H_2SO_4, and treated with hydrogen sulphide at 70° C. The whole is made up to 200 c.c., filtered through a dry filter, and 150 c.c. of the filtrate boiled to expel hydrogen sulphide, nearly neutralised with sodium carbonate, heated to boiling and added, in small portions, with vigorous agitation, to a boiling solution of sodium hydroxide (7—8 grms. per 0·1 grm. Zn). The whole is boiled for 5 mins., rapidly cooled, diluted to 500 c.c., and filtered through an alundum filter. In 100 c.c. of the filtrate the zinc is determined electrolytically by Frary's method (this J., 1907, 875, 1257).—A. S.

Copper ores; Notes on the leaching of oxidised —— by modified Dorr classifiers at the Butte-Duluth mine. C. S. Herzig. Inst. Min. and Met., May 21, 1914. [Advance proof.]

The old method consisted in crushing to about ½ in.-mesh and leaching in vats with 10% sulphuric acid for 48 hours; the extraction varied between 50 and 70 per cent. The introduction of Dorr classifiers, in which wood was substituted for metal in all parts in contact with the acid, resulted in an extraction of 85% after one hour's leaching. Six classifiers, 8 ft. wide, are used in series; the first four, 30 ft. long, for acid treatment, the last two, 15 ft. long, for washing with water. The ore is crushed to 10-mesh size, mixed with acid, and fed on to the first machine; the slime overflows at the lower end and is treated separately, while the coarser pulp drops into the second classifier which receives fresh acid. The overflow from the second, third and fourth machine is electrolysed; that from the last classifier but one is fed on to the first, while the wash from the last is treated with scrap iron.—W. R. S.

Copper mattes; Treatment of —— in the basic converter at the works of Korabach (Ural, Kishtim district.) K. D. Kolasnikow. Rev. Mét., 1914, 11, 519—543.

Mattes containing Cu 7—49, Fe 26—60, S 23—25%, are "blown" in two stages. The white matte, produced in the first stage, generally approximates to Cu_2S in composition. The coarse copper from the second stage contains Cu 98—99%, together with about 97% of the gold and 40% of the silver present in the white matte. The slag (containing Cu 1—2%) varies in composition from $3FeO,SiO_2$ to $2FeO,SiO_2$ according to the composition of the matte bath and the temperature. The complete data relating to the treatment of about 100 kilos. of matte containing Cu 33·5% are given and discussed in detail. —W. E. F. P.

Brass; Electrolytic deposition of ——. C. W. Bennett and A. W. Davison. Met. and Chem. Eng., 1914, 12, 340.

Brass cannot be deposited on a rotating cathode, except from cyanide solutions and then not satisfactorily. The ratio Cu : Zn in solutions suitable for the deposition of a brass varies not only with variations of free cyanide, but also with the rate of rotation of the cathode; beyond a certain limiting speed zinc alone is deposited.—B. N.

Cyanide in electroplating solutions; Determination of free —. G. E. F. Lundell. Met. and Chem. Eng., 1914, 12, 340.

A measured quantity of the cyanide solution, preferably containing from 0·2 to 0·5 grm. of cyanide, is diluted to 100 c.c., treated with 1 c.c. of ammonia solution, and 1 c.c. of a solution of 8·9 grms. of dimethylglyoxime in 1 litre of 95% alcohol, and titrated with a standardised nickel ammonium sulphate solution (containing 15·3 grms., with 5 c.c. of concentrated sulphuric acid, diluted to 1 litre) until a permanent red precipitate is formed. In the reaction one mol. of the nickel sulphate combines with 4 mols. of potassium cyanide.—B. N.

Sodium and potassium salts; Electrolysis of fused mixtures of ——. B. Neumann and E. Bergve. Z. Elektrochem., 1914, 20, 271—275.

The m. pt. of sodium hydroxide can be reduced by addition of potassium hydroxide to 167° C. (58·4% KOH). The addition of sodium carbonate to this mixture raises the m. pt. Sodium carbonate added to sodium hydroxide lowers the m. pt. to a minimum at 280° C. (17% Na_2CO_3), and a mixture of potassium and sodium carbonates (48·5% K_2CO_3, m. pt. 690° C.) will lower it to 265° C., when the melt will contain 79·3% NaOH. The electrolysis of mixtures of the fused salts yields alloys of potassium and sodium. With a constant current density the percentage of potassium in the alloy increases with that in the melt, and from a mixture of NaOH 60 and KOH 40%, the alloy contains the metals in the same ratio as the melt. With an increasing current density the potassium content of the alloy increases slowly both from hydroxide and carbonate melts.—W. H. P.

Metals; Internal strains in cold-wrought ——, and some troubles caused thereby. E. Heyn. Inst. of Metals, May, 1914. [Advance proof.]

Self-straining is produced where portions of a solid are given a tendency to assume different lengths, and when by cohesive forces they are hindered from following this tendency, and are forced to adapt themselves to a common length by elastic deformation. In a cold-drawn rod, the core tends to be stretched more than the outer layers, and hence is under compression whilst the outer layers are in tension. Cold-rolling and cold-hammering produce tension in the core and compression in the outer layers. By removing one portion, the other is allowed to assume its true length, and by measuring the change in length, a measure of the former strain is obtained. By removing successive thin layers the distribution of the longitudinal strains across a bar may be studied. Similarly by removing the core and measuring the change in diameter a measure of the transverse strains is obtained. Such measurements made on portions of the same material after annealing at different temperatures have shown that internal strains are partially removed at temperatures much below that at which the effects of cold work are completely removed. Several special cases are discussed, and it is shown that fracture and cracking of engineering materials are often the result primarily of considerable internal strain, the forces determining the fracture being relatively small. Liability to cracking, especially in alloys of copper and zinc, may often be revealed by dipping the piece in mercury or in solutions of mercury salts. It is possible to remove internal strains by alternate cold-drawing and cold-rolling. Results of tensile tests are largely dependent upon the amount of internal stresses, and upon the distribution of the latter over the sectional area of the bar tested. The tensile strength may even appear to be lowered instead of raised by cold work, owing to the effect indicated by the tensile test being completely masked by the effect of internal strain.—T. St.

Metals; Solidification, cellular networks and growth of grains in ——. F. Robin. Rev. Met., 1914, 11, 489—512.

By slow cooling, samples of aluminium, lead and tin were obtained in which, without any dendritic formation, the boundaries of the grains coincided exactly with the figures (network of lines) produced by contraction. It is suggested that the metal solidities in the amorphous condition and becomes divided (as indicated by the lines of contraction) into separate portions, each of which subsequently crystallises in one piece having a oniform orientation. The cellular network of metals is apparently not connected with local variations in density, but is favoured by the presence of impurities. The structure is formed abruptly in pure metals without apparent crystallites, and increases with a slight tinkling sound on cooling; it follows the contraction figures of amorphous materials, and is regarded as the result of concentration at the moment of solidification, due to crystallitic solidification or compression: it is not produced in bismuth (which expands on solidification). The growth of the grains on annealing is effected by the junction of crystals having the same orientation, or, more frequently, by diffusion across the joints the grains which develop being those having the greater internal tension and not necessarily the larger ones.—W. E. F. P.

Cadmium, copper and zinc. Physico-chemical studies on ——. I. E. Cohen and W. D. Helderman. Z. physik. Chem., 1914, **87**, 409—430.

Measurements of density after varying thermal treatment, and dilatometric measurements showed that cadmium, copper, and zinc, like tin and bismuth exist in a metastable form at ordinary temperature. The transition temperature is about 60 C. for cadmium and 70° C. for copper, but the value for zinc has not yet been determined. The transitions take place very slowly both above and below these temperatures so that all forms of the pure metals hitherto obtained are mixtures of at least two constituents, and their physical and mechanical constants refer to undefined systems. In the case of copper and cadmium the transition temperature varies a few degrees with the previous history and thermal treatment of the metal, suggesting the possible existence of three modifications.—W. H. P.

Metals and alloys; A method of obtaining a measure of the colour of ——. F. C. Thompson and E. Sinkinson. Chem. World, 1914, **3**, 132—135.

Details are given of a method of photographing metal surfaces under constant conditions of exposure and and development. The density of the resulting negatives is measured in a Sanger-Shepherd densometer, and the ratio of the density of the negative given by silver to that of the negative given by another metal is taken to express the degree of colour of that metal. Pure silver, and silver containing Cu 7·5 % were found to be indistinguishable, as were also pure copper, and copper with Sn 8·3 %. A German silver composed of Cu 57, Ni 7, Zn 36 %. gave a slightly higher colour figure than one composed of Cu 55, Ni 15, Zn 30 %.—T. St.

Colloidal gold solutions; Chemical and physico-chemical observations in the preparation of ——. W. Halle and E. Pribram. Ber., 1914, **47**, 1398—1401.

Attempts to prepare colloidal gold solutions containing particles of uniform size by Donau's method (Monats. Chem., 1913, **34**, 335) of bringing a hydrogen flame in contact with the surface of a dilute aqueous gold solution gave irregular results. It was observed that the gold solution (or pure water) after contact with the hydrogen flame contained small quantities of nitrous acid, and experiments in which the gold salt was reduced by nitrous acid irectly gave satisfactory results, colloidal gold solutions ontaining particles of uniform size and of different olours being easily obtained. For example 0·1 grm. f sodium nitrite was dissolved in 285·5 c.c. of water, he calculated quantity of $N/10$ sulphuric acid (14·5 c.c.) as added, and portions of 5 c.c. of this solution were reated with: (1) 145 c.c. of water and 3 drops of gold hloride solution (1 : 100), (2) 195 c.c. of water and 4 drops f gold chloride solution, and (3) 245 c.c. of water and 5 rops of gold chloride solution. After a short time lution (1) was of a uniform blue colour, solution (2) violet, and solution (3) red. In vessels of glass which yielded traces of alkali to the water, blue or bluish violet solutions were always obtained.—A. S.

Colloidal solutions of base metals; Preparation of aqueous —— by disintegration. D. Zavrieff. Z. physik. Chem., 1914, **87**, 507—510.

Colloidal aqueous solutions of aluminium, iron, magnesium, copper, lead, nickel, and mercury were prepared by electrical disintegration of the metals by oscillatory discharges produced by means of an induction coil or an influence machine.—A. S.

Working coke-ovens in conjunction with blast-furnaces. Freyn. *See* IIa.

Colorimetric determination of cobalt, nickel, iron, and copper. Hüttner. *See* XXIII.

Patents.

Steel; Manufacture of ——. G. J. Boyle, Doncaster. Eng. Pats. 1306, Jan. 16; 11,778, May 20; 12,961, June 4; 14,431, June 21; and 16,821, July 22, 1913.

A bath of molten steel of considerably greater depth than width, is subjected to the action of an electric current, which is caused to pass through the depth of the charge, so as to enable slag, gases, etc., to rise to the surface; the purified metal is discharged from the bottom of the receptacle.—W. E. F. P.

Iron and steel; Process for the manufacture of a metal combining the properties of ——. Syndicat de Procédés Métallurgiques. Fr. Pat. 464,717, Jan. 20, 1913.

Refined iron or steel is treated with alkali- and ammonium-salts (free from S. P. As, etc.) to modify the working qualities of the metal. For example, steel (1 ton) is rendered extra hard by treatment with a mixture of potassium bichromate (300 grms.), sodium bichromate (500), sodium chloride and bicarbonate (each 250), sodium borate and aluminate, potassium nitrate and ammonium chloride (each 100 grms.). The hardness is diminished by using smaller proportions of bichromates, borate and aluminate, and a soft metal is obtained by omitting these constituents from the mixture.—W. E. F. P.

Manganese-steel ingots: Process of treating ——. C. G. Osborne, Chicago, Ill. U.S. Pat. 1,094,090, April 21, 1914.

The ingots are stripped, quenched from a temperature of not less than 750° C., and then re-heated to about 1175° C.
—W. E. F. P.

[*Ferro-vanadium.*] *Metallurgical process.* W. F. Bleecker, Pittsburgh, Pa. U.S. Pat 1,094,114, April 21, 1914.

The high-carbon alloy, obtained by heating a mixture of ferric and vanadium oxides with fluxes and excess of reducing agent, is re-heated with a similar mixture containing no reducing agent to produce ferro-vanadium of low carbon content.—W. E. F. P.

Iron or its alloys: Cementation of ——. M. Caplain and L. Krieger. Fr. Pat. 465,715, Feb. 12, 1913.

The metal is embedded in carbon and heated in a current or atmosphere of nitrogen.—W. E. F. P.

Copper or other metals; Process for refining ——. W. S. Rockey and H. Eldridge, New York. Eng. Pat. 7409, March 28, 1913.

Copper is melted in an oil-fired furnace in a reducing atmosphere, and runs from the hearth into a ladle by way of a conduit which serves as a flue for the products of combustion. The roof of the conduit is shaped to deflect the issuing gases into the ladle, above which are a hood and vertical pipe for carrying away the gases. The metal is thus subjected to a refining deoxidising atmosphere until it is poured into the moulds.—T. St.

Copper alloys ; Process of producing ——. H. Bryda, Blackstone, Mass. U.S. Pat. 1,095,078, April 28, 1914.

Tin (1½ parts), quicklime (1½), tartar (1), magnesia (1) and sal ammoniac are added in succession to molten copper (16 parts), the mixture being stirred after each addition and allowed to stand for 30—45 mins. before pouring. —W. E. F. P.

Ores ; Apparatus for concentrating ——. S. Michaelis, Aranyida, Hungary. Eng. Pat. 10,972, May 9, 1913.

In the concentration of ores by flotation (with oil and acidulated water), incompletely isolated ore particles are separated from the residue obtained by removal of the first concentrate, by means of a rotary disc, of inverted, conical shape, provided, near the centre, with openings for the escape of gangue and, below the rim, with an annular channel in which the partly isolated, oily ore particles—suspended in acidulated water and moved over the rim by centrifugal action—are collected. A small cone having an annular channel around the rim is disposed beneath the disc for the purpose of collecting the escaping gangue. —W. E. F. P.

Ores ; Process for recovering metalliferous constituents of ——. J. T. Terry, jun., San Francisco, Cal. U.S. Pat. 1,094,760, April 28, 1914.

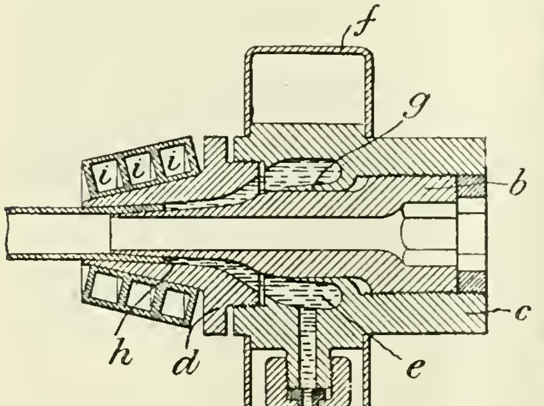
Non-sulphide ore pulp is treated with gaseous hydrogen sulphide, then subjected to reduced pressure, and finally concentrated by flotation. Before treatment with hydrogen sulphide the ore may be mixed with a soluble metallic salt to produce "nuclei for the formation of sulphide granules and coagulations."—W. E. F. P.

Concentration of oxide or carbonate ores by the flotation process. E. Langguth. Ger. Pat. 272,919, May 9, 1913.

The ore is treated with a solution of salts of aniline or its homologues, with or without addition of oil, and then concentrated by flotation in the usual manner.—A. S.

Lead or other metals or alloys ; Apparatus for the manufacture of tubes, cable casings and other products of indefinite length from molten ——. H. Debauge, Paris. Eng. Pat. 5230 of 1914, date of appl., March 6, 191 .

The molten metal is forced continuously through a die (see Fig.) comprising three main concentric parts, *b*, *c*, *d*, *b* and *d* being adjustably screwed into *c* for the purpose of regulating the thickness of the tube wall. The metal passes through the pressure pipe, *a*, into the chamber, *e*, which is maintained at a constant temperature by a bath of the metal contained in the bell, *f*, the latter being filled by tilting the apparatus. To prevent leakage through the screw joint between *b* and *c*, the central part of *c* is provided with a tubular portion of thin metal which slides on the inner part of the die and acts like the cup leather of a hydraulic press. From the chamber, *e*, the metal passes to the outlet nozzle around which a series of annular cooling chambers, *i*, are disposed for the purpose of regulating the position (*i.e.*, distance from the orifice) at which solidification of the metal is effected.—W. E. F. P.



Wire, plates and the like having a coating of gold ; Method for the manufacture of ——. E. Max, London, and F. Kammerer, Pforzheim, Germany. Eng. Pat. 27,222, Nov. 26, 1913.

The wire is coated electrolytically with gold and then passed between pressure rollers at a temperature lower than the softening point of the core to weld the deposit to the latter.—W. E. F. P.

[Gold and silver.] Metals ; Process of extraction of precious ——*from their carrier.* E. E. Howson, Salt Lake City, Utah. U.S. Pat. 1,093,700, April 21, 1914.

The ore pulp is made to form a relatively thin layer and the solution is removed from below during the formation of this layer. A solvent is then added, the mass agitated with a current of warm air, the solvent removed from below, a wash solution added, the mass again agitated with air and the solution removed as before.—W. E. F. P.

Air for blast furnaces ; Method of drying ——. M. W. Johnson, jun., Birmingham, Ala. U.S. Pat. 1,093,859, April 21, 1914.

The air is refrigerated at furnace pressure, the condensed moisture removed, and the dried air warmed by interchange of heat with the moist compressed air.—W. E. F. P.

Titanium carbide ; Method of producing a compound containing ——. A. J. Rossi and W. F. Meredith, Niagara Falls, N.Y., Assignors to The Titanium Alloy Manuf. Co., New York. U.S. Pat. 1,094,022, April 21, 1914.

A bath of molten metal, *e.g.*, iron, mixed with titanium oxide and carbon, is heated sufficiently to produce more titanium carbide than metallic titanium, and is then rapidly cooled to promote retention of the carbide particles.—F. Sodn.

Metals ; Process for extracting ——*from ores.* H. S. MacKay, Assignor to MacKay Process Co., Norwich, Conn. U.S. Pat. 1,094,371, April 21, 1914.

A solvent for ores is formed from the elements of the ore, by roasting (with or without addition of sulphur), leaching and electrolysing, the composition of the solvent and of the electrolyte being controlled by the character of the roast.—W. E. F. P.

Metallizing-furnace. E. P. Mathewson and F. Laist, Anaconda, Mont. U.S. Pat. 1,094,802, April 28, 1914.

The furnace consists of six superposed, communicating hearths—the upper ones for oxidation and the lower ones for reduction. The third hearth from the bottom is fired directly, the two below being muffle hearths heated externally by combustion chambers and supplied internally with solid reducing material. The waste gases from the combustion chambers are diverted to the directly-fired hearth, and the roasted ore is mixed with the reducing material in the muffle hearths.—W. E. F. P.

Furnace ; Metallurgical ——. U. Wedge, Ardmore, Pa. U.S. Pats. 1,094,953 and 1,094,954, April 28, 1914.

(1). In a furnace of the superposed-chamber type, two "manifolds"—one for supplying, and the other for receiving, air—are disposed within the central shaft and are connected with the interiors of the chambers by pipes and the hollow rabble arms. (2). The floor of each chamber is divided, by a low, circular partition, into two concentric zones along which different materials may be separately propelled by the action of one set of rabble arms. Means are provided for charging and discharging the concentric portions independently.—W. E. F. P.

Blast-furnace. J. M. Jantet. Fr. Pat. 466,241, Dec. 16, 1913.

A portion of the gases leaving the blast-furnace is aspirated through valve-controlled pipes and re-delivered to the furnace at the level of the tuyères.—T. St.

Furnace; Electric —— [for the production of ferro-alloys]. Soc. Electro-Métallurgique de Saint-Béron. Fr. Pat. 466,116, Feb. 20, 1913.

The material is contained in a crucible communicating below, by means of a channel, with a second crucible thus preventing entrance of slag into the latter, which has a pouring orifice at a level normally above that of the molten metal. Two electrodes, for the arrival and return of the current, are disposed above the first crucible and are movable vertically by a screw, so that when forced into the material some is discharged from the pouring orifice. These electrodes may be used only for leading in the current, which is then taken away by other electrodes around or above the second crucible. By employing electrodes of great cross-section, the furnace may be used as a resistance instead of an arc furnace.—B. N.

Furnace; [Metallurgical] Electric arc ——. I. Rennerfelt. Fr. Pat. 466,291, Nov. 17, 1913. Under Int. Conv., Dec. 5, 1912, and July 18, 1913.

The external iron envelope of the fusion chamber is divided into several equal sections, and each section carries a similar group of electrodes arranged in a plane perpendicular to the longitudinal axis of the furnace. Each group consists of two horizontal electrodes and a vertical one placed in the middle, or two horizontal electrodes, each turning on an axis so as to be displaceable in a vertical plane, may operate with one or more contacts in the base of the furnace. In another form, two vertical electrodes and two horizontal ones, operating from opposite sides of the furnace, are arranged in the same vertical plane. The furnace is turned about a horizontal axis, at one end, transverse to the longitudinal axis, whilst the other end may be raised or lowered; or the turning axis may be in the middle of the furnace or parallel to the length of the furnace. Openings are provided in one of the extreme walls above the normal level of the slag, so that on tilting the furnace the slag is rapidly poured, and openings closed by refractory material are arranged below for casting the charge. The vertical electrodes are connected to the common point of a diphase current, and the horizontal electrodes to the extremities of the phases. —B. N.

Ores; Treatment of sulphide, oxide, carbonate, and other ——. N. H. M. Dekker. First Addition, dated Feb. 5, 1913, to Fr. Pat. 445,768, July 4, 1912.

Certain oxide ores are best mixed with charcoal, sulphur, etc., before being treated with the polysulphate as described in the chief patent (see Eng. Pat. 18,488 of 1911; this J., 1912, 930). Sulphurous acid is thus formed which acts in the nascent state on the ores with formation of sulphates.—T. St.

[*Aluminium.*] *Metals; Solder for ——.* G. Koenig. Fr. Pat. 464,716, Jan. 20, 1913.

An alloy of Sn 60, Al 30 and Sb 10 parts by weight. —W. E. F. P.

Aluminium or its alloys; Preparing the surfaces of —— for receiving a metallic deposit. L'Aluminium Français. Fr. Pat. 464,720, Jan. 20, 1913.

To prepare aluminium articles for electro-plating an adherent metallic coating, free from occluded hydrogen, s produced upon them by immersing them in an acid hydrochloric) or alkaline bath containing tin or other uitable metal in solution, rinsing, immersing in a saturated olution of ammonium alum or other aluminium salt, and then for a few seconds in a solution of sulphuric or/and nitric acid.—W. E. F. P.

Nickel or other metals; Deposition of —— on aluminium, or other metals, glass or porcelain. L'Aluminium Française. Fr. Pat. 464,721, Jan. 20, 1913.

The article to be coated is immersed in a solution of a salt of the metal to be deposited, to which have been added ammonium or other alkali or metallic phosphites or hypophosphites, the solution being heated to increase the speed of deposition.—B. N.

Silvering aluminium, iron and steel electrolytically, without a preliminary coppering. P. F. L. Bévenot. Fr. Pat. 466,193, Feb. 24, 1913.

The metal is first coated electrolytically with a thin firmly-adherent layer of an alloy of nickel and silver by employing an electrolyte containing nickel, silver and potassium cyanides. A thicker deposit of silver may then be obtained from an ordinary plating bath.—B. N.

Zinc; Manufacture of pure zinc oxide or metallic ——. H. W. de Stucklé. Fr. Pat. 465,816, Dec. 6, 1913. Under Int. Conv., Dec. 7, 1912.

Precipitation (from solution of the sulphate, chloride, etc.), is effected by ammonium sulphite in the presence of ammonia or ammonium carbonate. The zinc sulphite is calcined to oxide and the sulphur dioxide evolved absorbed in a neutral, acid, or feebly alkaline solution of ammonium sulphite, the resulting ammonium bisulphite being reconverted into normal sulphite (for further use) by the addition of ammonia recovered from the filtrate from the original precipitation.—W. E. F. P.

Blende, and ores and metallurgical products containing blende; Method of dead-roasting ——. W. Buddeus. Fr. Pat. 466,397, Dec. 19, 1913. Under Int. Conv., Feb. 26, 1913.

Powdered blende is made into briquettes with an agglomerant such as calcium silicate, with the addition, if desired, of combustible substance. The porous nature of the briquettes permits of the sulphur content being reduced by roasting to below 1 to 2%.—T. St.

Zinc from residues, slags, and low-grade ores; Process and furnace for obtaining ——. O. Uehlendahl. Ger. Pat. 271,826, Feb. 15, 1913.

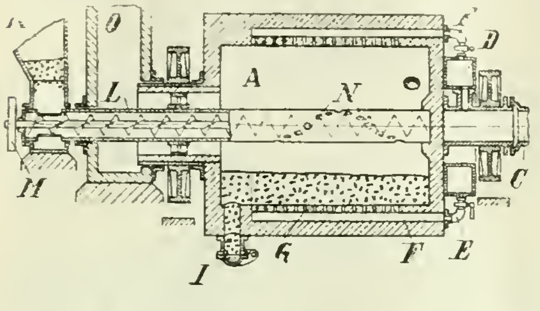
The charge is distributed on a number of movable hearths which pass successively through a tunnel furnace, a freshly-charged hearth being introduced at one end when a hearth containing a charge from which the zinc has been completely expelled is removed at the other end. The heating gases pass through the furnace in the opposite direction to the charge. The freshly charged hearths are not introduced directly into the furnace but into an intermediate chamber communicating therewith and not traversed by the heating gases. The tunnel furnace may be divided into two communicating parts through which the heating gases are passed independently, or it may be annular, the hearths taking a circular course. Other modified forms are also described.—A. S.

Zinc or other easily volatile metals; Process for obtaining ——. R. von Zelewski. Ger. Pat. 272,537, Dec. 8, 1912.

Zinc is obtained from a charge of the sulphide and calcium carbide by heating in large brickwork muffles similar to coke ovens, which are heated in the usual manner or electrically, the walls serving as a heating resistance. —A. S.

Metalliferous materials; Process and apparatus for treating materials, especially ——, with a view to roasting, reduction, volatilisation of metals, concretion, etc. F. C. W Timm. Fr. Pat. 465,951, Oct. 30, 1913. Under Int. Conv., Nov. 2, 1912.

The apparatus (see Fig.) consists of a horizontal or slightly inclined, cylindrical, rotary furnace, A, in the lining of which are disposed perforated sections, G, which communicate, through longitudinal passages, F, in the furnace wall with pipes, E, through which air is passed from an annular duct, D, supplied by a tuyère, C. The cylinder is charged with the material through an opening (not shown) similar to the discharge opening, I (both being normally closed), and carbon or carbonaceous matter added, in small quantities at a time, through openings, N, in a portion of the horizontal pipe, L, through which the carbon is conveyed from a hopper, K, by means of a worm actuated by a pulley, M. The gases and volatile products pass from the cylinder to the chamber, O, and are drawn off.—W. E. F. P.



Phosphate slag; [Thomas process] Method of converting the whole of the phosphorus into fluid ——, soluble in citrates, in the manufacture of steel by treating pig-iron and ore in the open-hearth furnace. Deutsch-Luxemburgische Bergwerks- und Hütten-Akt.-Ges. Fr. Pat. 466,016, Dec. 10, 1913.

To prevent the passage of phosphorus back to the metal, the slag is removed at two successive stages in the refining of the steel. After about $1\frac{1}{2}$ hours, when decarburisation first becomes intense, a large proportion of the phosphorus has been removed from the metal, and the slag is tapped off. Fresh ore is then added. Dephosphorisation again becomes rapid and decarburisation slow. After about an hour the latter again becomes intense, and the slag is again removed. If much silicon be present, it is removed in a preliminary acid slag, formed almost immediately by the addition of sufficient ore just to oxidise it, and a minimum quantity of lime. In a test the first dephosphorisation slag contained 21·94 % P_2O_5 of which 20·8% were soluble in citrates, and the second 19·6% P_2O_5, of which 18·71% were soluble.—T. St.

Alkali metals; Manufacture of —— by electrolysis of melted salts or mixtures of these. R. J. McNitt. Fr., Pat. 466,205, Dec. 15, 1913. Under Int. Conv., Jan. 2. 1913.

The zone of electrolysis, near the bottom of the bath, is placed under pressure by using a deep layer of the molten electrolyte; or the cathode chamber may be subjected to the pressure of an inactive gas, and pressure maintained in the anode chamber by preventing the escape of the gaseous products.—B. N.

Aluminium; Alloy of ——. R. Suchier. Fr. Pat. 466,293, Nov. 29, 1913.

A strong and light alloy of aluminium with 0·5 to 10% Ni and Cr.—T. St.

Metals or alloys, especially iron; Process for protecting —— against oxidation. K. Kaiser. Ger. Pat. 272,451, Jan. 21, 1913.

The metal is coated with a solution of a metallic salt, to which dextrin, gum, glue, shellac or the like may be added, then dried and heated to redness. Salts, especially the nitrates, of thorium, aluminium, magnesium, zirconium, and chromium, are mentioned. The metal becomes coated with a firmly adherent layer of the oxide of the metal the salt of which has been used.—A. S.

Iron; Method of working pure ——. R. B. Carnahan, jun., Middletown, Ohio, U.S.A. Eng. Pat. 28,571, Dec. 11, 1913. Under Int. Conv., Jan. 16, 1913.

See U.S. Pat. 1,090,115 of 1914; this J., 1914, 424.—T. F. B.

Furnace: Electric —— [for making steel]. T. Levoz, Heer, Belgium. U.S. Pat. 1,094,912, April 28, 1914.

See Fr. Pat. 417,597 of 1910; this J., 1911, 32.—T. F. B.

Iron ore and other minerals; Process for agglomerating ——. G. Crusius. Fr. Pat. 465,452, Nov. 28, 1913. Under Int. Conv., Nov. 30, 1912.

See Eng. Pat. 27,536 of 1913; this J., 1914, 488.—T.F.B.

Tungsten; Process for manufacturing articles or objects of ——. O. Voigtländer, Essen on Ruhr, Germany. Eng. Pat. 6911, March 20, 1913. Under Int. Conv., March 23, 1912.

See Fr. Pat. 455,313 of 1913; this J., 1913, 949.—T.F.B.

Tungsten; Manufacture o ——. C. Gladitz. Fr. Pat. 465.613, Dec. 3, 1913. Under Int. Conv., Dec. 3, 1912.

See Eng. Pat. 27.859 of 1912; this J., 1914, 204.—T.F.B.

Magnetic separators. F. Krupp Akt.-Ges. Grusonwerk, Magdeburg-Buckau, Germany. Eng. Pat. 24,355, Oct. 27, 1913. Under Int. Conv., Nov. 27, 1912.

See Fr. Pat. 454,156 of 1913; this J., 1914, 425.—T. F. B.

Aluminium and its alloys; Flux for —— and process for manufacturing the same. J. C. Gelly, Paris. Eng. Pat. 26,026, Nov. 13, 1913. Under Int. Conv., Nov. 15. 1912.

See Fr. Pat. 464,505 of 1913; this J., 1914, 489.—T. F. B.

Electroplating apparatus; Rotary ——. C. J. Charlton, South Benfleet. Eng. Pat. 30,047, Dec. 30, 1912.

See U.S. Pat. 1,093,384 of 1914; this J., 1914, 554.
—T. F. B.

Electroplating apparatus; Rotary ——. C. J. Charlton. Fr. Pat. 464,421, Nov. 4, 1913. Under Int. Conv., Dec. 31, 1912.

See U.S. Pat. 1,093,384 of 1914; this J., 1914, 554.—T.F.B.

Metals and their alloys; Process for the electrodeposition of ——. P. Marino. Fr. Pat. 466,105, Dec. 12, 1913. Under Int. Conv., Dec. 16, 1912.

See Eng. Pat. 28,953 of 1912; this J., 1914, 86.—T. F. B.

Metals; Process for the production of varied colorations and black shades on ——. F. A. Roux, Assignor to Soc. l'Aluminium Francais, Paris. U.S. Pat. 1,095,357, May 5, 1914.

See Fr. Pat. 464,722 of 1913; this J., 1914, 489.—T.F.B.

Galvanising or otherwise treating steel, iron, and other metals. H. H. Field, M. Howarth, and E. A. Atkins. Fr. Pat. 465,486, Nov. 29, 1913. Under Int. Conv., Nov. 30, 1912.

See Eng. Pat 27,641 of 1912; this J., 1914, 425.—T. F. B.

Precious metals; Process and apparatus for extracting, separating, and recovering —— from their ores. D. C. Reinohl. Fr. Pat. 466,072, Dec. 11, 1912.

See U.S. Pat. 1,081,516 of 1913; this J., 1914, 88.—T.F.B.

XI.—ELECTRO-CHEMISTRY.

Alternating current; The influence of superimposed —— on electrolysis by direct current. O. Reitlinger. Z. Elektrochem., 1914, 20, 261—269. (See also this J., 1911, 1221 and 1914, 426.)

The passage of an alternating current in addition to the direct current during electrolysis reduces the overvoltage and by diminishing the electrode potential makes it possible to isolate various intermediate products which would be destroyed at a higher potential. In the electrolysis of sulphuric acid the yield of persulphuric acid is diminished and that of ozone is increased. Solutions of alcohols in dilute sulphuric acid yield mainly aldehydes instead of acids, which is in accordance with previous observations that with a low anode potential alcohols are oxidised to aldehydes, whereas at higher potential acids are formed. By combining the effect of alternating and direct current in ammonia electrolysis 36 to 40 % current yields of nitrous acid can be obtained, although with direct current only it cannot be detected. In the electrolytic production of ozone experiments were also made with pulsating direct current instead of alternating current. When the pulsating-current was in the same direction as the continuous current it had little effect, but when it was in the opposite direction and of such a magnitude as to temporarily reverse the electrodes, the potential fell and the yield of ozone rose rapidly. This suggests that it is the negative portion of the alternating current which is responsible for its effect on electrolysis. When the frequency of the alternating or pulsating current was very high its action was much less pronounced, probably on account of the displacement of phase caused by the capacity of the electrodes.—W. H. P.

Electrolytic valve action of aluminium; Influence of impurities of the electrolyte upon the ——. G. Schulze. Z. Elektrochem., 1914, 20, 307—310.

The influence of small quantities of certain impurities in a saturated solution of borax upon the formation curve of an aluminium valve-electrode was very marked. Sodium halides, particularly sodium chloride even at a concentration of 0·05 % of that of the borax, exerted a disturbing influence, and electrolytes which give the least cloudiness with silver nitrate should be rejected. Sodium nitrate or potassium permanganate were less detrimental, but should not exceed 1·0 %. Sodium hydroxide was harmless unless present in such considerable quantities as to cause gradual solution of the aluminium. The above results apply also to other electrolytes in which aluminium shows good valve action.—G. F. M.

PATENTS.

Batteries; Electric ——. F. S. B. de Mello, Rio de Janeiro, Brazil. Eng. Pat. 24,471, Oct. 28, 1913. Under Int. Conv., Dec. 4, 1912.

Cuprous sulphide is reduced electrolytically in a solution of an alkali hydroxide, and the finely-divided colloidal copper, which is formed, is partly oxidised to cuprous oxide. On exposure to air at ordinary temperatures it forms a peroxide, suitable as a depolariser, which may be regenerated after use by washing with water and drying in contact with air.—B. N.

Electrode; Storage battery —— and process of manufacturing it. H. C. Hubbell, Newark, N.J. U.S. Pat. 1,094,903, April 28, 1914.

The active material is formed from precipitated ferrous hydroxide, which is filtered, washed, and heated out of contact with air to convert it into ferrous oxide. This is ground with cadmium oxide, and the mixture moulded into tablets suitable for insertion into the pockets of a containing envelope.—B. N.

Fluids [electrically]; Treating ——. H. T. Weston, Cleveland, Ohio. U.S. Pat. 1,094,618, April 28, 1914.

For the treatment of fluids by static discharges, a number of cells supported in a frame is used, each consisting of a pair of flat dielectrics and a flat conductor clamped between and in contact with the sides of the same. The cells are spaced apart by transparent distance pieces to llow the passage of the fluid to be treated. The spacing f the dielectrics is such that a certain intensity of disharge is obtained with a minimum expenditure of electrical energy. Each conductor has an extension projecting outwards beyond the dielectrics, with connectors pivoted to the extensions and loosely engaging with terminal conductors, whereby any of the cells can be disconnected and removed by swinging the connectors out of engagement with the conductors. The discharge may be observed through the transparent distance pieces, which comprise a rack open at two opposite sides for the entry and exit of the fluid.—B. N.

Electric separation of bodies in suspension in insulating fluids and particularly in gases; Process and apparatus for ——. E. Möller. First Addition, dated July 31, 1913 (Under Int. Conv., Aug. 10 and 31, 1912), to Fr. Pat. 449,337, July 31, 1912 (this J., 1913, 495).

The current of impure fluid to be treated is brought into a chamber where the speed is reduced, and it is then divided into several currents which pass through vertical tubes acting as separating elements. Smooth wires, stretched by weights, are arranged axially along the tubes and act as organs of ionisation. An open form of purifier is also described of gradually increasing diameter, so as to diminish the speed of flow of the fluid, and several groups of separating elements are arranged, one following the other. Various forms are given to these groups according to the composition of the fluids to be treated or the bodies in suspension, the various separating elements and organs of ionisation being arranged in a plane parallel to the flow of the fluid. The number of separating elements, mounted in parallel, is greatly increased in the wider part of the apparatus, and the distance between the electrodes is consequently less where the speed of the fluid is diminished. —B. N.

Electric furnaces; Impts. relating to the direction given to the gases in —— with arcs spread magnetically. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Fr. Pat. 466,109, Dec. 12, 1913. Under Int. Conv., Dec. 16, 1912.

The air or other gas is introduced either at right angles or tangentially to the arc, near to the point where it attains its greatest length, and in a direction opposed to its direction of movement, the gas being withdrawn at a point near to the place of production of the arc. Air or other cooling fluid is admitted through channels in the walls of the furnace, so as to cool the sides and central portions which are most exposed to the heat.—B. N.

Insulator; Electrical ——. J. W. Aylsworth, East Orange, N.J., Assignor to The Halogen Products Co., West Orange, N.J. U.S. Pat. 1,094,829, April 28, 1914.

The liquid insulator, in which electrical apparatus may be submerged, is prepared from a distilled mono-chloronaphthalene free from water, naphthalene, and higher substitution products, by treating it with alkali, removing traces of free alkali from the liquid, and dissolving an anhydride in it.—B. N.

Electrolytes; Purifying ——. F. von Kügelgen and F. von Bidder, Holcombs Rock, Va., and G. O. Seward, East Orange, N.J., Assignors to Virginia Laboratory Co., New York. U.S. Pat. 1,095,609, May 5, 1914.

A salt, such as sodium chloride, is purified by fusing it between electrodes in a crucible formed of the solid salt, and is then subjected to the action of a suitable current, whilst maintaining a pool of sodium over it, until the heavier impurities are precipitated. Direct current is employed, using a molten cathode of heavy metal, to decompose the less electro-positive impurities, the foreign metals being precipitated and absorbed by the molten cathode, and the purified salt is then decomposed by electrolysis.—B. N.

Electrolytic apparatus. W. Thum, Hammond, Ind. U.S. Pat. 1,095,748, May 5, 1914.

The apparatus comprises a framework, which supports a number of compartments, forming suitable tanks of strength sufficient merely to support an electrolyte and anode slimes within the compartments. The sides of the latter carry conductors and insulating bars, upon which rest several electrodes so that they may be easily removed —B. N.

Electric arcs; Process and apparatus for the production of long continuous ——. O. Schönherr, Dresden-Striesen, Germany, and J. Hessberger, Christiansand, Assignor to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pats. 1,095,425, 1,095,426, and 1,095,427, May 5, 1914.

See Fr. Pat. 410,710 of 1909; this J., 1910, 829.—T. F. B.

Electrodes in electric arc furnaces; Protecting the ——. J. I. Bronn, W. Schemmann and Rombacher Hüttenwerke. Fr. Pat. 466,265, Dec. 17, 1913. Under Int. Conv., Dec. 18, 1912.

See Eng. Pat. 29,259 of 1913; this J., 1914, 555.—B. N.

Cathodes for electric furnaces. Sodium Process Co. Fr. Pat. 466,445, Dec. 20, 1913.

See U.S. Pat. 1,092,178 of 1914; this J., 1914, 555.—B.N.

XII.—FATS; OILS; WAXES.

Fats; Contribution to the study of ——. *Indices of refraction of: (I.) Mixtures of olein, stearin and palmitin; (II.) Mixtures of palmitic, stearic and oleic acids.* P. Pascal. Bull. Soc. Chim., 1914, 15, 360—367, 397—401.

The indices of refraction of a large number of binary and ternary mixtures of olein, stearin and palmitin were determined at 60°, 70° and 80° C. With mixtures of palmitin and stearin the temperature coefficient increased from 0·00025 per 1° C. for palmitin to a maximum of 0·00045 for a mixture of equal proportions of the constituents, and then fell progressively to 0·00028 for stearin. The values for palmitin and stearin were $n_D^{70} = 1·4402$ and 1·4413 respectively. The temperature coefficient for mixtures of palmitin and olein increased regularly with increasing quantities of olein from 0·00026 to 0·00038, the value of n_D^{70} for olein being 1·4523. Mixtures of stearin and olein exhibited, though in a lesser degree than palmitin and stearin, a maximum in the temperature coefficient, which occurred when the quantity of olein present was about 70 %, the value for a mixture containing stearin 27·27 and olein 72·73 % being 0·00043 per 1° C. The values for the indices of refraction of ternary mixtures of olein, stearin and palmitin were plotted on a triangle. With mixtures giving indices below 1·4440 at 70° C. the curve formed an almost straight line, whilst with mixtures giving higher readings the curve became progressively concave. Similar determinations were made with mixtures of oleic, stearic and palmitic acids. The values of n_D^{70} for palmitic and stearic acids were 1·4304 and 1·4335 respectively, the temperature coefficient for mixtures rising regularly with increasing quantities of the latter from 0·00035 to 0·00039 per 1° C. Oleic acid had a refractive index at 70° C. of 1·4415 and when mixed in increasing quantity with palmitic acid the temperature coefficient fell to a minimum of 0·0003 for mixtures containing 50—60 % of the latter, whilst in the case of mixtures of oleic and stearic acids the reverse was the case, the coefficient rising to a maximum of 0·0005 with mixtures containing 20—30 % of the solid acid. The results of observations on ternary mixtures of the three acids were plotted on a triangle. It is suggested that with the knowledge of another property of the mixture, *e.g.*, the iodine value, it would be possible to determine the composition of any mixture of the three glycerides or of the three acids from the given curves.—J. A.

Fatty substances of linen and hemp; Characters of the ——. A. Bianchi and G. Malatesta. Annali Chim. Appl., 1914, 1, 297—302.

The fatty matter of raw linen, extracted by carbon tetrachloride (yield 2—2·5 %), was a brown, brittle waxy substance, sparingly soluble in cold organic solvents but readily soluble in hot benzene and chloroform. Its characters were: sp. gr. 0·9980 at 15° C., m. pt. 68°—70° C., acid value, 23—23·8; iodine value, 17—17·5. The saponification value by the ordinary method was 111·9, but rose to 156—163 on prolonging the treatment up to 6 hours. The unsaponifiable matter (20—23 %), was a brittle brown substance, m. pt. 73°—74° C., sp. gr. 0·986, free from phytosterol, and consisting mainly of hydrocarbons. Hemp yielded 0·5—1·2 % of fatty matter of somewhat similar character to that obtained from linen; m.pt. 66°—67° C., sp. gr. 1·019; acid value, 46—47; iodine value, 22·2—22·8; saponification value (6 hours), 187—192. It contained 11 % of unsaponifiable matter of m. pt. 60° C., sp. gr. 1·0022.—A. S.

Turkey-red oil; Analysis of ——. W. Herbig. Färber-Zeit., 1914, 25, 169—171; 194—196.

The potassium salts of ricinoleic and sulphoricinoleic acids are soluble to a large extent in cold acetone, but the sodium salts are so sparingly soluble that the neutral fat in Turkey-red oils may be separated from the sodium salts almost quantitatively by acetone. From 2 to 5 grms. of the oil, according to the amount of water as determined by Fahrion's method (this J., 1913, 1118), are neutralised with *N*/1 or *N*/10 alkali, evaporated to dryness on the water bath, and the residue dried by Fahrion's method (*loc. cit.*). The dried mass (which must not have been over-heated) is boiled with four successive portions (75 c.c. each) of anhydrous acetone, each extract being cooled with ice and decanted through a filter. The solution is evaporated, the residue of oil weighed, and its acid and saponification values determined. The separated salts are readily soluble in hot water, yielding a solution ranging from faint yellow to deep yellow ("monopol soap"). This solution is treated with boiling hydrochloric acid to liberate combined sulphuric acid and fatty acids, the latter being subsequently extracted with ether and examined. From 66 % ("monopol soap") to 77 % (Turkey-red oil) of the total sulphuric acid was found in the salts insoluble in acetone. The ratios between the percentages of acetone extract and fatty acids were:—"Monopol soap," 1·13; Turkey-red oils, 1·45 and 1·78. The sum of the water and total fat constituted about 90 % of the samples of oil (84 % in the case of "monopol soap"). This affords a practical sorting test. (See also this J., 1914, 32, 266.)—C. A. M.

Changes occurring in oils and paste paints due to autohydrolysis of the glycerides. Gardner. See XIII.

Repeated use of lubricating oil after filtration. Fenno. *See* I.

Patents.

Oil, juice and water or moisture from oil-containing seeds, nuts, fruits, fish and materials or substances generally which contain oil, juice or moisture; Apparatus for expressing ——. G. R. Schueler, Kingston-upon-Hull. Eng. Pat. 9130, Apr. 18, 1913.

The material is forced by one or more rotating sweepers through spaces between vanes or other devices to produce compression, contained in a combined expressing chamber and filter-box. The oil, etc. escapes through holes in plates within the chamber, whilst the residual mass is discharged through an annular opening, the size of which may be regulated, or which may be entirely closed. —C. A. M.

Grain residues; Treatment of —— *after extraction o oil by solvents.* Harburger Eisen- u. Bronzewerk Aktienges. and G. Koeber, Harburg, Germany. Eng Pat. 28,261, Dec. 8, 1913.

The residues in the extractors are moistened and treate with a current of steam at ordinary or reduced pressur in order to remove the remaining solvent. After the steaming, a vacuum is created in the extractors to remove the excess of moisture.—C. A. M.

Cottonseed oil residues; Process of treating and refining ——. C. Epler, Bogorodsk, Russia. U.S. Pat. 1,094,430, Apr. 28, 1914.

The residue (mucilage) is boiled with a solution of caustic soda and common salt, and the resulting precipitated mass bleached with chloride of lime, and treated with sulphuric acid to separate the fatty acids, which are then washed with steam (in the presence of salt) and clarified and dried at 100° C.—C. A. M.

Edible oils; Process and apparatus for treating [hydrogenating] composite ——. C. Ellis, Montclair, N.J. U.S. Pat. 1,095,144, Apr. 28, 1914.

The hot melted fat (*e.g.*, a mixture of edible cottonseed and maize oils) is made to move across the path of a bubbling current of hydrogen in the presence of a catalytic agent.—C. A. M.

Soap; Manufacture and application of a new ——. R. Weiss. 1st Addition, dated Nov. 10, 1913 (under Int. Conv., Nov. 11, 1912), to Fr. Pat. 448,490, Nov. 27, 1912 (this J., 1913, 435).

The soap previously described (*loc. cit.*) is specially suitable as a dressing or finish for linen. The treated linen retains its whiteness on exposure. Its suppleness may be increased by the addition to the soap of substances, such as vaseline or mineral oil, which do not impart odour or colour.—C. A. M.

Floating soaps; Process of manufacturing compact —— *and products thereof.* C. Muller. 1st Addition, dated Nov. 13, 1913, to Fr. Pat. 462,502, Sept. 12, 1913 (this J., 1914, 324).

A certain proportion of sodium silicate with or without a solution of potassium or sodium carbonate or potassium chloride is added after saponification.—C. A. M.

Soap with a basis of petroleum or other hydrocarbons; Process of manufacturing a new ——. P. A. Cattaert. Fr. Pat. 466,151, Feb. 21, 1913.

Oleic or other fatty acids or deglycerinated oils are treated with petroleum or other hydrocarbons (preferably at about 60° C.) in the presence of a trace of a condensation agent, such aluminium chloride, ferric chloride, nitro-derivatives of phenol, etc., and the mass subsequently saponified to obtain a soap which is soluble in water.
—C. A. M.

Soaps; Process of increasing the efficacy and hardness of neutral —— *by mixing them with hydrocarbons.* C. Pleines. Fr. Pat. 466,331, Dec. 17, 1913.

Hydrocarbons are incorporated with neutral soaps within definite limits of temperature.—C. A. M.

Candles; Process of manufacturing composite ——. J. P. Laursen-Schjödt. Fr. Pat. 466,027, Dec. 10, 1913.

Oleine, stearine or analogous substances are dissolved in alcohol, ether, oil of turpentine, chloroform or other readily combustible solvent, the solution treated with alkaline lye in calculated quantity, and the saponified mass mixed with paraffin wax in sufficient proportion to obtain candle material of the desired whiteness and fineness.—C. A. M.

Fats and oils; Process and apparatus for the decomposition of ——. B. E. Reuter, Chicago, U.S.A. Eng. Pat. 10,199, April 30, 1913.

ee U.S.Pat. 1,068,079 of 1913; this J., 1913, 875.—T. F. B.

Lubricating grease; Manufacture of ——. R. Haddan, London. From Chem. Fabr. Troisdorf Dr. Hulsberg und Seiler, Troisdorf, Germany. Eng. Pat. 16,480, July 17, 1913.

See Fr. Pat. 460,418 of 1913; this J., 1914, 90.—T. F. B.

Fatty acids; Bleaching of ——. B. E. Reuter, Chicago, U.S.A. Eng. Pat. 27,867, April 30, 1913.

See Fr. Pat. 457,496 of 1913; this J., 1913, 1020.—T. F. B.

Oils; Process for moistening the residues from the manufacture of —— *and for extracting the solvents by means of steam, with or without a vacuum.* Harburger Eisen und Bronzewerke A.-G. Fr. Pat. 465,641, Dec. 4, 1913.

See Eng. Pat. 28,261 of 1913; preceding.—T. F. B.

Fats, fatty oils, mineral waxes, or mineral oils; Process for solidifying —— *and converting them into dry pulverulent products by means of malt extract or maltodextrin.* M. Hamburg. Fr. Pat. 466,419, Dec. 20, 1913. Under Int. Conv., Dec. 21, 1912.

See Eng. Pat. 29,481 of 1912; this J., 1913, 672.—T. F. B.

Manufacture of oil varnish substitutes from animal oils. Eng. Pat. 21,835. *See* XIII.

Substitute for boiled linseed oil. Ger. Pat. 272,465. *See* XIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Basic lead carbonate; Nature of ——. E. Euston. J. Ind. Eng. Chem., 1914, 6, 382—383.

It was shown previously (this J., 1914, 363) that white lead is probably a mixture of normal lead carbonate with a basic carbonate of the composition, $PbCO_3.Pb(OH)_2$. The lead hydroxide portion of this basic carbonate is soluble in ammonium chloride solution but not in sucrose solution, and the basic salt is regarded as an "adsorption compound." White lead and normal lead carbonate when stirred with a solution of basic lead acetate withdrew lead hydroxide from the solution, yielding, on prolonged treatment, products containing as little as 10·1% CO_2. Basic zinc carbonate, whiting or precipitated calcium carbonate, precipitated barium sulphate, and precipitated barium carbonate behaved in a similar manner, yielding products of approximately the composition, $ZnCO_3.Zn(OH)_2.3Pb(OH)_2$; $2CaCO_3.Pb(OH)_2$; $3BaSO_4.Pb(OH)_2$, and $3BaCO_3.2Pb(OH)_2$ respectively. The lead hydroxide portion of all these compounds was soluble in ammonium chloride solution but not in sucrose solution. The calcium compound and the barium sulphate compound were of no use for paints, but the other two had properties similar to those of white lead. The basic zinc carbonate compound was equal and the barium carbonate compound considerably superior to white lead in regard to being tinted or for covering quality.—A. S.

Oils and paste paints: Changes occurring in —— *due to autohydrolysis of the glycerides.* H. A. Gardner. J. Franklin Inst., 1914, 177, 533—540.

The presence of enzymes in micro-organisms derived from infected seed, etc., appears to be responsible for the granular condition of certain oil paints. A sample of lead paint which had become granular contained lumps from which were separated a liquid fatty acid with neutralisation value of about 180, a solid fatty product with acid value, 84, and a metallic paint in combination with part of the fatty acid as an insoluble soap. A sample of linseed oil which had caused a paint to thicken in 6 to 12 months had the following characters:—Sp. gr. 0·9450; iodine value, 171·3; saponif. value, 133·2; acid value, 4·1; "foots," 9·0%; and moisture and volatile matter, 0·68%. The "foots" had an acid value of 6·9, whilst the oil, after separation from the "foots," showed normal values (iodine value, 177·3; saponif. value, 190·2; acid value, 3·9). Cultures prepared from the "foots" at 37° C. on agar-agar yielded characteristic bacilli resembling the hay bacillus. The paint prepared with this oil showed increased acid value after incubation for a week at 37° C. A sample of cloudy oil upon which moulds readily developed, was mixed with pure linseed oil and a few drops of water containing carbon dioxide. At the end of 48 hours the acid value had increased by 10%. The growth of moulds was not prevented by the addition of small quantities of antiseptics (phenol, cresol, salicylic acid, etc.), but was inhibited by heating the oil to at least 100° C. soon after expression. It is suggested that only oils containing little "foots" and sterilised in this manner should be used for grinding with paint materials. A similar treatment may be found effective for preventing the development of rancidity and malodorous products in fish oils, etc.—C. A. M.

Oil in oil-paints; Determination of ——. F. A. Mazza. Ann. Falsif., 1914, 7, 210—211.

Nicolardot's method (this J., 1913, 202) has the drawback that particles of paint pass through the filter paper with the toluene. This is obviated by heating 2 to 3 grms. of the paint on the water bath with a mixture of alcohol and ether (2 : 3), and collecting the insoluble matter on counterpoised filter papers, which are dried in the oven and weighed. The amount of oil is found by difference.—C. A. M.

Oil of turpentine; Detection and determination of petroleum products in ——. C. Grimaldi and L. Prussia. Annali Chim. Appl., 1914, 1, 324—338.

The method suggested is based on the oxidation of the oil of turpentine by mercuric acetate to products soluble in dilute nitric acid. 75 grms. of mercuric acetate are placed in a graduated 500 c.c. flask, having also graduations of $\frac{1}{5}$ c.c. (from 0 to 10 c.c.) on the neck. 200 c.c. of water, 100 c.c. of glacial acetic acid, and 10 c.c. of the oil under examination are added in the order given, and the whole is heated for 2 hours at 80° C. under a reflux condenser, with frequent agitation. After cooling, nitric acid (2 parts of acid of sp. gr. 1·4 to 1 part of water) is added until the liquid reaches the zero mark, the whole is well shaken, allowed to settle, and the volume of unattacked oil noted. It is possible by this test to detect 6—12% of petroleum benzine, 8—10% of turpentine substitutes (light petroleum) and 10% of petrol in oil of turpentine. Control determinations without oil of turpentine showed that there is an unavoidable loss of 0·5—0·7 c.c. in the case of benzine and 0·35—0·50 c.c. in that of petrol, in carrying out the determination.—A. S.

Wood distillation under diminished pressure. A contribution to the problem of the utilisation of wood waste. Adams and Hilton. *See* IIb.

Determination of the higher lead oxides. I. Iodometric method. Milbauer and Pivnica. *See* VII.

Patents.

Inks for printing machines; Composition of ——. W. E. Heyl and T. T. Baker, London. Eng. Pat. 10,055, April 29, 1913.

About 0·25% of sodium amyl sulphate is added to the ink to increase the rate of drying and thus prevent smearing.—C. A. M.

Lead oxide; Production of —— *and means or apparatus employed therein.* W. Innes, Liverpool. Eng. Pat. 10,387, May 2, 1913. Addition to Eng. Pat. 15,664, July 4, 1912.

Baffle-plates or other deflecting means are placed at one side of the oxide pot of the apparatus claimed in the chief patent (this J., 1913, 1066) to prevent the outlet becoming choked with fine particles of lead or lead oxide. —C. A. M.

Rust-preventive products; Manufacture of ——. Standard Lack- und Farbwerke Zürich-Altstetten. Fr. Pat. 466,304, Dec. 6, 1913. Under Int. Conv., Dec. 7, 1912.

Aqueous solutions of inorganic substances (chromic acid and chromates, alkali carbonates, alkaline-earth hydroxides), which prevent the rusting of iron, are mixed or emulsified with hydrocarbons, fats, oils, resins, powdered clay, chalk or other substances which do not inhibit the rust-preventing action, and the products are used for coating iron and steel.—A. S.

Submarine paints; Use of fluorides and fluorine-compounds for the manufacture of ——. G. Paterno and C. Manuelli. Fr. Pat. 466,368, Dec. 18, 1913.

Fluorides or fluosilicates of aluminium, zinc, lead, or other metals are used in the preparation of submarine paints.—A. S.

Mercury salts; Preparation of solutions of —— *in vegetable or animal oils, fats, waxes, and the like, resistant to water.* Gebr. Avenarius and J. Wolff. Ger. Pat. 272,605, Nov. 7, 1912.

Complex aromatic mercury salts are dissolved in an organic solvent and the solution dissolved in or mixed with oils, waxes, or the like. Or, the organic solvent may be dissolved in or mixed with oils or the like before introducing the mercury salt. The products may be used for the preparation of anti-fouling submarine paints, etc. —A. S.

Oil varnish substitutes from animal oils; Process for the manufacture of ——. W. Kaempfe, Grossenhain, Saxony. Eng. Pat. 21,835, March 15, 1913. Addition to Eng. Pat. 15,012, June 27, 1912.

The fractional hydrolysis of the animal oil as claimed in the chief patent (this J., 1913, 436) may be effected by means of an enzyme such as that of *Ricinus*, the hydrolysed products then being removed as described. (See also Fr. Pat. 445,565 of 1912; this J., 1913, 34).—C. A. M.

Linseed oil; Substitute for boiled ——. E. F. Waentig. Ger. Pat. 272,465, Dec. 17, 1910.

Fish oils, marine animal oils, and the like are heated for a short time at 235°—240° C., then steam superheated to 375°—400° C. is blown through for 25—30 hours, whereby glycerides of saturated fatty acids are hydrolysed and the products of hydrolysis distilled, whilst the glycerides of unsaturated acids are polymerised and remain behind. The drying power of the product is superior to that of linseed oil.—A. S.

Varnish composition; Non-inflammable ——. J. W. Aylsworth, East Orange, N.J., Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,094,830, April 28, 1914.

A mixture of 100 parts of acetylcellulose and 100 parts of a dehydrated phenol resin dissolved in 1000 parts of a water-free volatile solvent, such as acetylene tetrachloride.—B. N.

Sulphite-cellulose extracts; Use of —— *for the preparatio of varnish.* L. Meunier. Fr. Pat. 466,196, Feb. 24 1913.

A varnish giving rapidly drying, uniform coatings i prepared by mixing commercial concentrated sulphite cellulose extract with a substance, especially a solutio of a terpene in a sulphoricinate, which diminishes th surface tension of the product. For example, 4 litres o oil of turpentine are added gradually, with constan agitation, to 25 kilos. of neutral sodium sulphoricinat heated to 60° C., and the resulting thick liquid is inco porated with 25 times its weight of sulphite-cellulo extract of 30° B. (sp. gr. 1·263).—A. S.

Plastic and elastic substances; Manufacture of ——. J. Stockhausen. Fr. Pat. 466,435, Dec. 20, 1913. Under Int. Conv., Dec. 20, 1912.

Plastic substances prepared from glycerin and gelatin are rendered resistant to water, whilst retaining their elasticity, by incorporating with them a resinous condensation product of phenol and formaldehyde. *Example.* A solution of 2·5 kilos. of gelatin in 2·5 kilos. of glycerin is mixed with a solution of 0·5 – 1 kilo. of camphor in acetone, 2—4 kilos. of powdered asbestos, 0·3—1 kilo. of sulphur, 0·5 kilo. of German black ("*noir d'Allemagne*"), and 1—1·5 kilos. of a resinous condensation product of phenol and formaldehyde.—A. S.

Adhesive resinous preparations and process of producing the same. H. Wolff, Assignor to Gebr. Schubert, Berlin. U.S. Pat. 1,095,058, April 28, 1914.

Erratum.

This Journal, May 30, 1914, p. 557, col. 2, delete lines 9—12 from the bottom, and replace by the following:—"R. B. Earle, Assignor to Hood Rubber Co., Boston, U.S. Pat. 1,093,923, April 21, 1914."

XV.—LEATHER; BONE; HORN; GLUE.

[Tanning] Extracts; The colour measurement of ——. H. R. Procter. J. Amer. Leather Chem. Assoc., 1914 **9**, 225—227.

The method of the International Association of Leather Trades Chemists of estimating colour by drumming sheep grain, preserved and delimed in a boro-phenol solution, in very weak liquors is capable of improvement. Split hide or shaved calf skins would probably give better and more even results for sole leather tanners and Seymour-Jones' formic acid mercury treatment is suggested as a preserving method. In the official method the use of ¼ % solution of tanning matter raised to ½ % as tanning proceeds is prescribed but a more practical method would be to commence with 200 c.c. of water and to dissolve in 200 c.c. a quantity of extract about double that required for tannage and add this solution 20 c.c. at a time every five minutes until the whole is given and then carry on the tannage to the end of two hours. The sample should be dried rapidly in the dark or protected from strong light. Oiling and cold drying give brighter shades but drying unoiled and at a higher temperature is the severer test for the extract. Methods in which white broadcloth and gelatinised cotton cloth are substituted for skin will probably never be made sufficiently accurate to serve as a basis of contract. For the direct optical measurement of the colour of the extract, the author (this J., 1910, 663) has suggested a method in which a uniform standard of glasses of 10 units of colour is used, but Kerr has found that recent glasses issued by the Tintometer Company are not strictly comparable in the Schmidt and Haensch colorimeter used, and therefore useless as a standard. Although the optical colour of any one make of extract is fairly proportionate to that which it will produce on leather, it is never satisfactory for the comparison of two different makes as the effect on leather depends not only on the visible colours but on the special tannins which they may contain.—D.J.L.

Tannery practice; A new emulsifying agent and its application to ——. E. D. Van Tassel, jun. J. Amer. Leather Chem. Assoc., 1914, **9**, 236—238.

Amides of the higher fatty acids, such as stearamide and also lecithin and tyrosine are capable of emulsifying large proportions of neutral fats and oils. Stearamide, a white crystalline compound (m. pt. 110° C.), resistant to acids and alkalis, is capable of emulsifying 5—15 times its weight of the oils used in leather manufacture such as neatsfoot oil, moellon degras, fish oil, etc., and will also emulsify substances such as tallow, some mineral oils and paraffin wax. The stearamide is heated to 185°—200° F. (85°—93° C.) in a steam-jacketed vessel and the oil or grease, previously melted, is run in with vigorous stirring. The required amount of water is then added and stirring continued till an even mixture is obtained. In stearamide emulsions animal oils and greases are practically odourless, and the odour of fish oils is considerably diminished. Emulsions of heavy mineral oil produced in this way form very satisfactory fat liquors. Paraffin wax emulsified by stearamide gives a full feel and improved "break" due to its filling action, and the effect is better than that produced by using the melted wax.—D. J. L.

Alkaline sulphides [in lime liquors]; Determination of ——. D. McCandlish and J. A. Wilson. J. Amer. Leather Chem. Assoc., 1914, **9**, 203—207. (See also this J., 1913, 152.)

A method is provisionally suggested which consists in precipitating the sulphides with excess of a standardised solution of cupric sulphate containing sulphuric acid, and determining the excess of copper colorimetrically after addition of ammonia.—D. J. L.

Leather; Determination of acidity of ——. P. Nicolardot. Ann. Falsif., 1914, **7**, 195—202.

The most reliable method of determining the total sulphur in leather is by combustion with oxygen in a bomb under a pressure of 10 atmos. To determine the acidity the leather is freed from fat by extraction with chloroform, boiled for 3 hours with water, and the liquid titrated (with litmus paper as indicator). Sulphuric acid and soluble sulphates are precipitated with barium chloride. As a control a second portion of the sample is boiled for 3 hours with the same quantity of water containing barium carbonate, and the acidity of the filtrate determined as before. After precipitation of dissolved barium by the addition of sulphuric acid, the liquid is filtered and evaporated, and the residue ignited and tested for barium not precipitable by sulphuric acid.—C. A. M.

Patents.

Skins, hides and the like; Method for dressing ——. R. Brooks, Goxhill, Lincolnshire. Eng. Pat. 23,638, Oct. 18, 1913.

The skins are impregnated with an aqueous extract of "brains," then pulled across a sharp board or the like and dried and rendered waterproof by hanging in smoke produced by burning touchwood or the like until they are of a yellowish brown colour throughout.—D. J. L.

Rawhide; Method of treating —— and the product resulting therefrom. A. H. Henderson, Assignor to The Henderson Rubber Co., Baltimore, Md. U.S. Pat. 1,094,853, Apr. 28, 1914.

Rawhide is "expanded" in an aqueous solution of a substance which will produce osmotic pressure in the cells of the hide and a deliquescent polyhydric alcohol, and is then subjected to heat in the presence of an oily vehicle and a fixed oil. Rubber may also be introduced "into the interior of the hide" and subsequently vulcanised. An article of manufacture consisting of a consolidated mass of granules or fragments of rawhide with a deliquescent polyhydric alcohol and vulcanised rubber is also claimed.—D. J. L.

Leather; Drying japanned or varnished ——. A. Genthe, Assignor to C. Heyl, Worms, Germany. U.S. Pat. 1,095,498, May 5, 1914.

See Eng. Pat. 20,795 of 1913; this J., 1914, 95.—T. F. B.

Chrome tanning; Process of ——. F. Hirsch. Fr. Pat. 465,846, Dec. 6, 1913. Under Int. Conv., March 8, 1913.

See Ger. Pat. 271,585 of 1913; this J., 1914, 559.—T. F. B.

XVI.—SOILS; FERTILISERS.

Nitrogen in mixtures of calcium nitrate and cyanamide; Determination of ——. A. Stutzer. Chem.-Zeit., 1914, **38**, 597.

Nitrate and nitrite are first determined by Schlösing's method (reaction with ferrous chloride), and then a portion, rendered free from nitrate, is treated by Kjeldahl's method. By heating 1 grm. with 5 grms. of dry ferrous chloride and 25 c.c. of concentrated hydrochloric acid, under slight pressure (in a flask fitted with a Bunsen valve), the nitrate may be completely eliminated on the water-bath in half an hour. In preparing a mixture of calcium nitrate and cyanamide, for use as a fertiliser, loss of nitrogen is liable to occur if the temperature be raised above 60° C.—F. Sodn.

Patent.

Phosphoric acid; Process of producing available ——. W. S. Landis, Niagara Falls, Ontario, Assignor to American Cyanamid Co., Nashville, Tenn. U.S. Pat. 1,094,857, April 28, 1914.

A finely ground mixture of phosphate rock and a soluble sodium salt, *e.g.*, sodium sulphate, is mixed with water, dried rapidly so as to prevent appreciable crystallisation of the sodium sulphate, and then calcined to convert the tricalcium phosphate into a soluble compound.—A. S.

XVII.—SUGARS; STARCHES; GUMS.

Sugar cane; Experiments in thinning out ——. A. H. Rosenfeld. Intern. Sugar J., 1914, **16**, 220—221.

Experiments showed that thinning out is not advantageous in the cultivation of the sugar cane, the production of sugar per acre being considerably less than when the ordinary procedure is followed.—J. P. O.

Lime content; Investigations on the —— of [cane] juices. W. E. Cross. Intern. Sugar J., 1914, **16**, 212—220.

Raw cane juices were found to contain from 0·025 to 0·09 grm. CaO in 100 c.c. In applying the carbonatation process, and using more than 1 % of lime, after saturation the clarified juice contained less lime than the original raw juice, so that, *e.g.*, with 2 % of lime so small an amount as 0·03 grm. CaO in 100 c.c. could be obtained. With the defecation-sulphitation process, on the other hand, the greater the initial sulphitation the higher was the lime content of the clarified juice. Sodium carbonate wher added to a clarified juice had only a very slight effect ir diminishing the lime content, as much as 3 lb. per ton o cane, for example, causing a reduction of 28 % only of th original amount of lime present. Phosphoric acid and disodium phosphate also had little effect in diminishing the lime content. In these experiments the lime was determined by titration with standard alcoholic soa solution, the results being controlled by the gravimetri method.—J. P. O.

Sugar house control analyses; Limit of error in certain ——. N. Deerr. Intern. Sugar J., 1914, **16**, 222—223.

Determinations of the water and sugar in mill bagass were made during 24 hours at intervals of 1, 2, and hours respectively, and the arithmetical mean and th probable error of the results were calculated. Th percentage extraction of sugar from the cane calculate from the arithmetical mean of the results was practicall the same whether the samples were taken at intervals 1, 2, or 4 hours, but the probable error was only reduce to reasonable limits when samples were taken eve hour.—J. P. O.

[Sugar.] Vacuum pan; Rate of evaporation in a ——. N. Deerr. Intern. Sugar J., 1914, **16**, 210—211.

Using a lyre coil pan of 2700 cb. ft. strike capacity, a 2455 sq. ft. heating surface, and heating with boiler stea of 90 lb. gauge pressure reduced to 40 lb., it was fou that the maximum rate of evaporation occurs just aft all the heating surface is put into action, and that aft about 10 minutes the rate rapidly falls, decreasi eventually to one-third the maximum rate. The ra per sq. ft. of heating surface is, however, at a maxim during the first hour of operation, and by the time th all the heating surface is in action, the rate per sq.

has already fallen, although the rate of production of vapour increases for at least 10 minutes. With very large pans, owing to the unevenness of the rate of evaporation, "peaked loads" in the rate of steam consumption inevitably occur, but this can be prevented by the distribution of the heating surface over a number of units. It is concluded that there should never be less than 3 units (pans) of equal size, so that a nearly uniform rate of evaporation spread over the different units can be attained.—J. P. O.

Molasses desaccharification; Formation of strontium formate in the waste product from —— by the strontia process. K. Urban. Z. Zuckerind. Böhm., 1914, **38**, 358—363.

In the strontia molasses desaccharification process the strontium bisaccharate separated is allowed to cool, when it decomposes into sugar and crystalline strontium hydroxide, which latter is washed in centrifugals with sweet-water, being afterwards heaped in the open air to be regenerated. After a time the temperature of the mass of so-called "centrifugal salt" gradually rises, commencing at the outside and slowly reaching the centre, 85° C. being sometimes reached. Investigation showed that this is due to the decomposition of the sugar necessarily remaining in the waste product as the result of washing with sweet-water; strontium formate is principally formed at first and later is converted into strontium carbonate.—J. P. O.

Sugars; Resolution of racemic —— by means of optically active amyl-mercaptan, and the properties of some mercaptals. E. Votocek and V. Vesely. Ber., 1914, **47**, 1515—1519.

i-Arabinose was resolved by combination with a pure *d*-amyl-mercaptan and fractional crystallisation of the mixture of mercaptals from alcohol. The method is probably applicable to other aldoses. The amyl alcohol from which the mercaptan was prepared was isolated from fusel oil (20 litres of which yielded 40 grms.) by rectification, saturation with hydrogen chloride, further rectification, combination with 3-nitrophthalic acid, and fractional crystallisation and hydrolysis of the ester (m. pt. 114·8°—115·2° C.). The optical rotation of the pure alcohol was —9·60° in a 200 mm. tube, and the characters of the mercaptan were: b. pt. 119°—121° C. (uncorr.), sp. gr. 0·8415 at 23° C., and $[\alpha]_D = + 3{\cdot}21°$ at 23° C. The melting points of a number of pure *d*-amyl- and isoamyl-mercaptals of aldoses are given.—J. H. L.

Starches; Diverse nature of ——. C. Tanret. Comptes rend., 1914, **158**, 1353—1356.

Starches from a number of different kinds of plants were all found to contain the amylopectin and amyloses of Maquenne and Roux (this J., 1906, 192, 601). The proportions of the constituents varied in the different starches, the amylopectin-content ranging from 67 % in chestnut starch to 79·5 % in banana starch. The amyloses of the different starches were not equally soluble in hot water, and the amylopectin of potato starch, unlike that of other starches, dissolved fairly readily in boiling water. An aqueous solution containing both amylose and amylopectin may be freed from the former by soaking cotton in it. The liquid expressed from the steeped cotton gives with iodine a violet colour characteristic of amylopectin, whilst the cotton gives a blue colour.

—L. E.

Patents.

ugar cane juices; Process of purifying and clarifying raw ——. R. E. Gordon, Wallaceburg, Ontario. U.S. Pat. 1,094,436, April 28, 1914.

HE raw juice is heated to above 90° C., cooled quickly, eed from precipitated impurities, treated with lime nd carbonatated, heated to above 90° C. whilst the lcium carbonate is still present, and again freed from ecipitated impurities, the treatment with lime, etc., ing then repeated.—L. E.

Sugar juices; Process of combined sulphitation within definite limits, for purifying and decolourising ——. J. Weisberg. First Addition, dated Jan. 30, 1913, to Fr. Pat. 455,936, June 5, 1912 (this J., 1913, 955).

The mud precipitated during the second carbonatation contains calcium sulphite, and is added to the raw juice together with the lime used for the first defecation. The amount of lime required is thus diminished, and the clarification of the juice is improved.—L. E.

Sugar juices; Removal of non-sugars from ——. G. Oehlrich. Fr. Pat. 465,580, Dec. 2, 1913. Under Int. Conv., Dec. 4, 1912 and Feb. 17, 1913.

Diffusion juice is treated first with a metallic sulphate, preferably iron sulphate, then with pure milk of lime, and saturated with carbon dioxide or a mixture of this gas and sulphur dioxide until the alkalinity is reduced to say 0·01 %. The treatment with lime and saturation are repeated once or, if necessary, twice, any iron in the juice being removed before the third treatment with lime, by addition of calcium sulphide or polysulphide. The defecated juice is concentrated *in vacuo* to 62°—65° Brix, heated to 100° C., filtered, saturated with sulphur dioxide until slightly acid, made alkaline, nearly neutralised with sulphur dioxide, heated to 90°—100° C., filtered, boiled to massecuite *in vacuo*, and centrifuged. The mother syrup from each operation may be worked up in succeeding operations until sufficiently charged with salts to be suitable for working up into second jet sugar. The waste syrup finally obtained is diluted to about 60° Brix, cooled, and filtered or centrifuged to remove the alkali sulphates; the sulphates remaining in the mother liquor are separated in the form of alums.—L. E.

Sugar beetroots; Preliminary treatment of —— to obtain juice. M. Lindner. Fr. Pat. 466,021, Dec. 10, 1913. Under Int. Conv., Dec. 11, 1912, and Dec. 1, 1913.

The syrups or molasses obtained as described in Ger. Pat. 268,530 of 1912 (this J., 1914, 212), are treated at 70°—80° C. with colloidal alumina and then with diluted milk of lime or lime water, and the mixture is boiled and filtered.

—T. F. B.

Sugar cane and similar saccharine material; Extraction of juice from ——. O. Mengelbier, Berlin. Eng. Pat. 15,070, June 30, 1913. Under Int. Conv., Oct. 19, 1912.

See Ger. Pat. 261,999 of 1912; this J., 1913, 920.—T.F.B.

Sugar from molasses; Process of obtaining ——. A. Grantzdörffer, Assignor to A. List, Magdeburg, Germany. U.S. Pat. 1,095,852, May 5, 1914.

See Fr. Pat. 460,192 of 1913; this J., 1914, 36.—T. F. B.

Process for rendering amylaceous substances soluble. Fr. Pat. 466,275. *See* VI.

XVIII.—FERMENTATION INDUSTRIES.

Yeast preparations; Enzymatic formation of polysaccharides by ——. A. Harden and W. J. Young. Biochem. J., 1913, 7, 630—636.

In the alcoholic fermentation of dextrose and lævulose by Lebedeff's maceration extract of dried yeast, dextrorotatory polysaccharides are formed, the product, in the case of lævulose being of a glycogen-like nature (cp. Cremer, this J., 1899, 777). The difference between the amount of sugar removed and that equivalent to the carbon dioxide evolved during fermentation with yeast juice (this J., 1904, 450) is chiefly due to the formation of these polysaccharides.—L. E.

Yeast fermentation without sugar. XVI. Question of the formation of lactic acid in the fermentation of pyruvic acid by living yeast, and remarks on fermentation processes. C. Neuberg and J. Kerb. Biochem. Zeits., 1914, **62**, 489—497. (See also this J., 1914, 37, 496.)

The fermentation of pyruvic acid by living yeast resembles that of sugar, in that no lactic acid is formed as by-product. For the investigation of the formation of lactic acid in cell-free fermentation, Buchner's pressed juice is preferable to maceration juice, since the latter, especially when prepared from commercial dried yeast, is liable to be infected with acid-forming bacteria (cp. Oppenheimer, this J., 1914, 156). The much greater production of lactic acid from glyceraldehyde than from sugar, observed by Oppenheimer (*loc. cit.*) with respect to cell-free fermentation, is evidence against the assumption that glyceraldehyde, as an intermediate product of fermentation, is the immediate precursor of the lactic acid formed from sugar.—J. H. L.

Phytochemical reductions. II. Transformation of fatty nitro-compounds into amines. III. Transformation of aromatic and fatty-aromatic aldehydes into alcohols. C. Neuberg and E. Welde. *IV. Formation of n-amyl alcohol by yeast. Natural occurrence of n-amyl alcohol.* C. Neuberg and F. F. Nord. Biochem. Zeits., 1914, **62**, 470—488. (See this J., 1914, 434.)

Living yeast in course of fermentation reduces nitroethane and nitromethane to ethylamine and methylamine respectively. In an experiment similar to those carried out with nitrobenzene (*loc. cit.*), about 3 grms. of ethylamine were obtained from 20 grms. of nitroethane. Fermenting yeast, which has already been shown capable of reducing fatty aldehydes and furfural (see Neuberg and Steenbock, this J., 1913, 813 ; Lintner and v. Liebig, this J., 1911, 915 ; 1913, 1081) will also reduce benzaldehyde and phenylacetaldehyde, the yields obtained in the two cases being 20—30% of benzyl alcohol and 65—70% of phenylethyl alcohol. Experiments having shown that *n*-valeraldehyde can be reduced to *n*-amyl alcohol by living yeast, with a yield of 70%, the authors investigated fusel oil (from fermented molasses) for this alcohol and found it present in very small quantities. It is doubtless derived from *n*-aminocaproic acid (norleucin) which, as Abderhalden and Weil have recently shown (Z. physiol. Chem., 1913, **84**, 39 ; **88**, 272), occurs in small quantities as a constituent of some proteins.—J. H. L

Acetaldehyde ; Production of —— during the anaerobic fermentation of dextrose by Bacillus coli communis (Escherich). E. C. Grey. Biochem. J., 1913, **7**, 359—363.

A small quantity of acetaldehyde is formed by the action of *B. coli communis* on dextrose under anaerobic conditions, but much less or none at all is formed by the variety of *B. coli* obtained by growth on agar containing sodium chloroacetate (c.p. Harden and Penfold, this J., 1912 894). Since this variety of *B. coli* produces no gas, and less alcohol and acetic acid than the original organism, the formation of acetaldehyde by the latter is related to the formation of alcohol, carbon dioxide and hydrogen rather than to the other products, and it is suggested that the acetaldehyde is a primary product of the fermentation, a suggestion in accord with Kostytschew's view that acetaldehyde is an intermediate product of alcoholic fermentation (see this J., 1912, 553).—L. E.

Rums ; Composition of ——. Bonis. Ann. Falsif., 1914, **7**, 164—166.

Since 1902 rums distilled from sugar cane juice which has been defecated with lime, have been exported from Martinique to France for blending with molasses rums. The old figures for the non-alcoholic coefficient no longer afford any certain means of distinguishing between the two classes of rums. The ratio of esters to higher alcohols is less than 1 in the case of sugar cane juice rums and some molasses rums. Using the values of this ratio as abscissæ, and the sums of the esters and higher alcohols as ordinates the points of intersection fall within a well-defined zone in the case of pure rums, and above or below this zone respectively in the case of rums containing added essential oil or industrial alcohol in appreciable quantity.—C. A. M.

Specific reaction for ethyl alcohol. Method of identifying it in presence of aldehyde, acetone, methyl alcohol, etc. Tominelli. *See* XX.

Patents.

Brewing processes. E. W. Kuhn, Brussels. Eng. Pats. 7456 and 9170, April 18, 1913.

(1) Malt is mashed in water at 10° C., and the extract filtered, the starch separated thereby being added to the mashed malt ; the process is repeated until the enzymes which act on carbohydrates are almost completely extracted, the less soluble proteolytic enzymes remaining in the malt. The malt is then added to water at 50° C., kept at this temperature for several hours to peptonise the albumin, added to boiling water and boiled for one or more hours to gelatinise the starch, cooled to 80° C., treated with the cold extract first obtained, and kept at 80° C., with stirring, to convert the starch paste into soluble dextrins. The peptonisation and dextrinisation may be increased by addition of active pepsin and amylase respectively, and both processes may be accelerated by addition of about 0·15% of phosphoric acid to the malt. (2) Malt is macerated in water at say 10° C., and the extract filtered and treated with about 60 c.c. of phosphoric acid per 100 litres. The macerated malt is added to boiling water, boiled for one hour, cooled to 80° C., treated with the cold extract, and, if necessary, with active amylase, and kept at 80° C. for two hours with stirring. The starch is thus converted into soluble dextrins, whilst the albumin, which is not subjected to proteolytic action at any stage, is coagulated and remains in the dregs.—L. E.

Grape marcs ; Process of treating —— for the extraction of various useful products. E. Disdier. First Addition, dated Nov. 17, 1913, to Fr. Pat. 458,344, May 24, 1913 (this J., 1913, 1081).

If the marc has been partially or completely fermented, the alcohol is recovered either by volatilisation in steam or in the form of low-grade wine by diffusion, the marc then being dried. The oil is extracted from the seeds with say petroleum ether, and the tannin and resins are extracted from the residue with alcohol. The alcoholic extract is distilled ; the residue may be treated with water which dissolves the tannin and the bulk of the colouring matters.—L. F.

Wood ; Process of treating —— with a view to its conversion into carburetted alcohol. G. Boulais and P. E Lefevre. Fr. Pat. 465,534, Feb. 7, 1913.

The process is based on the power of wood charcoa to absorb a large quantity of sulphur dioxide which i almost entirely liberated on heating the charcoal to 100° Wood fibre is placed in layers alternating with layers wood charcoal containing sulphur dioxide, the whol being heated in an autoclave until the fibre is sufficientl disintegrated, and then allowed to cool. The fibre i then saccharified with dilute acid, the product bein fermented and distilled ; the unsaccharified residu which has been reduced to a minimum by the treatme with sulphurous acid, is distilled, the methane, ethylen methyl alcohol and acetone thereby obtained bein utilised for carburetting the ethyl alcohol.—L. E.

Yeast or ferments for use in fermentation and distillation processes. A. Molhant, Mons, Belgium. Eng. Pat. 11,617, May 19, 1913. Under Int. Conv., May 25, 1912.

Beer free from alcohol; Process for making ——. K. Kroupa and L. Bochmann. Fr. Pat. 466,396, Dec. 19, 1913. Under Int. Conv., Dec. 19, 1912.

See Eng. Pat. 29,314 of 1913; this J., 1914, 497.—T. F. B.

XIXa.—FOODS.

Casein and paracasein compounds; Composition and properties of some —— and their relation to cheese. L. L. van Slyke and A. W. Bosworth. New York Agric. Expt. Stat., Tech. Bull., No. 26, Dec. 1912, pp. 1—32.

Pure casein was prepared from separated milk by repeated precipitation and solution, the final product being then extracted with alcohol and ether and dried over sulphuric acid under reduced pressure; it contained less than 0·1% of ash. A basic calcium caseinate, obtained by decomposing calcium carbonate with casein, or by treating casein with an excess of calcium hydroxide solution and neutralising the excess with hydrochloric acid, contained 1·78% Ca (or 2·50% CaO). Acid or unsaturated caseinates of ammonium, sodium, and potassium were also prepared; these compounds contained: NH_4, 0·20, Na, 0·26, and K, 0·44%, respectively. Two sets of compounds, monobasic and dibasic, may be obtained with casein and calcium, barium, and strontium hydroxides. In the dibasic compounds (containing twice as much base as the monobasic) 100 grms. of casein combine with 0·45 grm. Ca, 0·98 grm. Sr, or 1·54 grm. Ba. On the basis of these results the molecular weight of casein is calculated to be 8888, and its equivalent weight 1111.

Paracasein, obtained by treating separated milk with rennet, yielded a calcium paracaseinate similar in composition and properties to basic calcium caseinate, and also acid compounds containing NH_4, 0·40, Na, 0·52, and K, 0·88%, respectively. The mono- and di-basic calcium, strontium, and barium paracaseinates obtained had properties resembling those of the corresponding caseinates. In both cases, the monobasic compounds were insoluble in water, but soluble in 5% solutions of sodium, ammonium, or potassium chlorides; the dibasic compounds were soluble in water. Paracasein has one-half the molecular weight of casein, and, when casein is treated with rennet-enzyme, it appears to be split up into two mols. of paracasein. During the ripening of cheese (cheddar and many other kinds) a protein is always formed which is insoluble in water, but soluble in a 5% solution of sodium chloride; this protein is identical with mono-calcium paracaseinate.—W. P. S.

Cellulose in flours; Determination of —— to ascertain the degree of grading. L. Lindet. Ann. Falsif., 1914, 7, 169—171.

Ten grms. of the flour are freed from fat by extraction with petroleum spirit or ether, dried, and boiled with 400 c.c. of hydrochloric acid (sp. gr. 1·025) for 30 mins. The liquid is treated with 50 c.c. of a 10% solution of hydrated aluminium sulphate, ammonia is added, and the precipitate of alumina, which retains the cellulose, is separated, washed, and mixed with water and boiled for an hour with 10 grms. of solid sodium hydroxide per 100 c.c. of liquid, to dissolve impurities in the cellulose. After cooling, the liquid is neutralised with hydrochloric acid, and the aluminium hydroxide reprecipitated by ammonia. The alumina in the precipitate containing the pure cellulose is dissolved in hydrochloric acid, the residue of cellulose is dried and weighed, and any ash present deducted. Samples of flour separated into six grades by Pekars' method gave the following percentages of cellulose:—0·30; 0·59; 0·61; 0·69; 0·96 and 1·29. The results obtained with commercial grades sold as 40, 60 and 70% were as follows:—

Grade.	Water.	Fat.	Nitrogenous substances.	Cellulose.	Mineral matter.	Phosphoric acid.
	Per cent.	Per cent.	Per cent.	Per cent	Per cent.	Per cent
40	13·66	0·75	11·20	0·20	0·40	0·19
60	14·08	0·76	11 37	0·42	0·50	0·25
70	13·88	0·80	11·91	0·87	0·53	0·48

—C. A. M.

Flour; Milling of wheat and testing of ——. H. McCormack. J. Ind. Eng. Chem., 1914, 6, 423—428.

A discussion of the methods for the laboratory milling of wheat and chemical examination of flour. The results obtained in different laboratories with a given sample of flour are fairly concordant, but widely varying results are obtained in the case of wheat, this being due chiefly to variations in the laboratory methods of milling. The apparatus used by the author for milling the wheat is described and the adoption of uniform methods is advocated.—A. S.

Patent.

Cacao powder; Process for preparing an easily soluble —— without the use of chemicals. J. Bergmüller, Leipzig-Lindenau, Germany. Eng. Pat. 14,758, June 26, 1913.

See Fr. Pat. 459,675 of 1913; this J., 1913, 1168.—T. F. B.

XIXb.—WATER PURIFICATION; SANITATION.

Colloidal matter; Significance of —— in sewage disposal. F. R. O'Shaughnessy. J. Inst. Sanitary Eng., 1914, 18, 19—31.

Additional facts are recorded, mainly in tabular form, relating to the part played by colloids in sewage treatment, based on the author's experience with Birmingham sewage. The colloids originate chiefly from fæces. When fæces is shaken with water, 70% goes into solution and nearly 80% of this dissolved portion is in the colloidal state. In sewage, the colloids are removed with difficulty and only incompletely by precipitants unless used in prohibitive quantities; lime up to 3 parts per 100,000 actually increased the colloids, only at 15 parts or over was much precipitation obtained and even then it was incomplete. Experiments were made on the rate of elimination of the organic matter, corresponding to the colloids, in sewage coming through a long series of tanks and sewers under septic and non-septic conditions. The results obtained were: elimination in sedimentary tanks 0·68 part per hour (septic) and 0·76 part per hour (non-septic); in second tanks 0·2 part and 0·03 part; in five-mile sewer 0·57 part and 0·34 part; in the silt tanks 0·28 part and 0·38 part; in the biological filters 10 parts and 10 parts; total colloids removed during 22 hours, 55% and 50%. Retention in tanks is only effective in removing colloids when a considerable tank surface is exposed to the liquid and the effect then noticed appears due to biological action, for it was observed that in chlorinated and unchlorinated sewage passing through tanks, the organic matter was reduced from 10·75 parts per 100,000 to 9·22 parts in the untreated sewage, but only to 10·72 parts in the chlorinated sewage. Colloids deposit slowly from sewage, and in four different sewages the amount so deposited in 6 days varied from 12·1 to 7·5 parts per 100,000. Effluents from bacteria beds contain a certain amount of colloidal matter, and an instance of the subsequent removal of this is given, in which the effluent was passed through two pools, in the second of which long

grass was grown; in this latter the effluent was rendered brilliantly clear owing to the enormous surface offered by the grass. In sludge, the use of lime in moderate quantities does not effect the separation of the water, and the large quantities added in sludge pressing are necessary because of the attraction between the water and the colloids.
—J. H. J.

Thiosulphate; Oxidation of —— by certain bacteria in pure culture. W. T. Lockett. Proc. Roy. Soc., 1914, B, **87**, 441—444.

It had been found that the effluents from sewage filters containing thiosulphates were completely oxidised by aeration in presence of living organisms (see this J., 1913, 579). Attempts to isolate the organisms concerned in this oxidation failed when ordinary cultivation media were used; but a solid medium prepared from solutions of ammonium sulphate and sodium thiosulphate, and gelatin, gave a growth of slow growing, non-liquefying, bluish white colonies. About 100,000 of these colonies were present per c.c. These organisms when inoculated into a solution containing sodium thiosulphate and other salts produced a white stringy growth at 20° C., and after three weeks the whole of the thiosulphate was oxidised to acid sulphate; no deposition of sulphur nor formation of thionic acids occurred. Prolonged contact with slightly acid solutions impaired the activity and growth of the organism.—J. H. J.

Sulphurous and sulphuric acids in the atmosphere; Damage caused to vegetation by ——. R. R. Tatlock and R. T. Thomson. Analyst, 1914, **39**, 203—210.

Sulphurous and sulphuric acids were determined as sulphates in the acidified aqueous extracts of grass, oak-leaves, bracken, etc., taken from districts with atmospheres ranging from exceptionally pure to exceptionally polluted with smoke. The results, calculated as SO_3 upon the dried substance, showed that it is not justifiable to conclude that plants containing more than a certain proportion of sulphates have been injured by sulphurous or sulphuric acid, unless free acid is also present. For example, grass grown in a fairly pure atmosphere, contains up to 0·3% SO_3, but may contain as much as 1·0%, without injury, in the absence of free acid. Injured bracken contained 0·356% SO_3, or more than double that of an uninjured sample, but there was also free acid. Acid and damaged oak leaves contained only 0·202% SO_3, as against 0·42% in uninjured leaves, whilst healthy birch leaves contained 0·86% as compared with 0·248% in acid and injured leaves. The atmosphere of cities consuming much coal was found to be only exceptionally or locally acid, as for example when coal containing much sulphur (5 to 6%) was burned; but after diffusion of the fumes acidity in the surrounding atmosphere could not be detected.—C. A. M.

Acetylene; Physiological characteristics of —— with respect to its use in mining. E. E. Smith. Internat. Acetylene Assoc., 1913. School of Mines Quart., 1914, **35**, 143—153.

From experiments on the human subject it was concluded that acetylene generated from carbide had no poisonous action, four men having been allowed to remain in an atmosphere containing 2·5% for over two hours without any noticeable effect. With higher proportions the gas merely acted as a narcotic. Flame extinction occurred with an oil lamp at 13% and with an acetylene lamp at 26% of carbon dioxide in a still atmosphere, but at 10% and 17% with moderate motion.—F. Shdn.

Patents.

Water; Means for filtering —— in reservoirs. Puech, Chabal et Cie., and A. Puech, Paris. Eng. Pat. 11,284, May 14, 1913. Addition to Eng. Pat. 24,011 of 1909, dated Nov. 25, 1908.

Compressed air is supplied, through distribution chambers, to perforated concrete pipes supported above the bottom of the filter tank and which in turn support the perforated slabs constituting the false-bottom carrying the filtering material.—W. P. S.

House and town refuse; Treatment of ——. A. D. Furse, Beckenham, Kent. Eng. Pat. 20,232, Sept. 8, 1913.

The refuse is passed through a disintegrator, then between fluted rollers into a perforated cylinder where the mass is subjected to pressure by means of a screw-worm. The compressed refuse is screened to separate fluffy material and the screened material ground to a powder.—W. P. S.

Refuse material; Apparatus for incinerating ——. T. E. Wasley, San Jose, Cal. U.S. Pat. 1,094,503, April 28, 1914.

A drying chamber for the refuse is situated directly over a furnace, sliding plates being provided in the floor of the chamber so that the dried material may be discharged into the furnace. The drying chamber and the furnace each communicate with a condenser, that communicating with the furnace being connected with a stack fitted with a water-spray; the water flowing from the stack is collected in a settling tank.—W. P. S.

Impregnating fabrics with insecticidal substances; Process of ——. W. Wildt. Ger. Pat. 272,822, Aug. 29, 1913.

The fabric (cushions, etc.) is treated first with formaldehyde solution and then with ammonia solution. The formaldehyde acts as an insecticide when applied and then combines with the ammonia to form hexamethylenetetramine, which subsequently is slowly decomposed with re-formation of formaldehyde.—A. S.

Water-softening agents; Manufacture of ——. A. G. Bloxam, London. From Verein. Seidenfärbereien C. A. Langenbeck und T. P. Lohe, Elberfeld, Germany. Eng. Pat. 9755, April 25, 1913.

See Fr. Pat. 463,044 of 1913; this J., 1914, 331.—T. F. B.

Water: Process of purifying —— from germs by means of bromine. M. Riegel, Berlin. U.S. Pat. 1,094,475, April 28, 1914.

See Ger. Pat. 272,271 of 1913; this J., 1914, 564.—T. F. B.

Oxidising process [for treatment of water, etc.]. L. Linden, Brussels. U.S. Pat. 1,094,731, April 28, 1914.

See Eng. Pat. 20,556 of 1911; this J., 1912, 508.—T. F. B.

Waste water; Apparatus for purifying ——. E. Mann and J. Heess, Ebertsheim, Germany. U.S. Pat. 1,095,409, May 5, 1914.

See Fr. Pat. 464,483 of 1913; this J., 1914, 478.—T. F. B.

Sludges extracted from residual waters of all kinds; Process for carrying out the fermentation and agitation of —— and apparatus therefor. Comp. Claricite, Paris. Eng. Pat. 24,726, Oct. 30, 1913. Under Int. Conv., Nov. 25, 1912.

See Fr. Pat. 462,573 of 1912; this J., 1914, 331.—T. F. B.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Ipecacuanha root; Alkaloids of true ——. O. Hesse, Annalen, 1914, **405**, 1—57. (See also this J., 1895, 384; 1898, 869; 1901, 500.)

Finely-powdered ipecacuanha root (*Cephaelis ipecacuanha*, Richard) was moistened with cold sodium carbonate solution (1 part of calcined soda to 3 of water), and extracted with a mixture of benzene and petroleum benzine (1 : 5) at 60°—70° C. The alkaloids were removed from the extract by means of $N/10$ sulphuric acid, the acid solution treated with excess of ammonia, and extracted with ether. The ether solution was concentrated and shaken with successive portions of $N/5$ sodium hydroxide till the alkaline solution remained clear on addition of ammonium chloride. The alkaline solution was diluted with an equal volume of water, washed with ether, treated first with a slight excess of hydrochloric acid, then with ammonia, and the precipitated cephaeline dissolved in ether and crystallised. The ether solution of emetine, after washing with sodium hydroxide solution as described, was mixed with an ethereal solution of oxalic acid, added gradually, in small portions, the ether poured off, the precipitate dissolved in warm water, and the emetine converted into hydrobromide by addition of a saturated solution of sodium bromide. From the bromide mother-liquor, a new alkaloid, *ipecamine*, was precipitated by ammonia. When the original sulphuric acid solution of the alkaloids was treated with ammonia and extracted with ether, psychotrine remained dissolved in the ammoniacal solution, imparting to it a blue fluorescence; it was extracted by chloroform. In the purification of the emetine hydrobromide by recrystallisation from water, the mother-liquor was found to contain a fifth alkaloid, *hydroipecamine*, which was separated from emetine by fractional precipitation with sodium bromide. The composition of the five alkaloids is: emetine, $C_{26}H_{27}(OCH_3)_4(OH)N_2$; Cephaeline and hydroipecamine, $C_{25}H_{28}(OCH_3)_3(OH)N_2$; psychotrine and ipecamine, $C_{25}H_{26}(OCH_3)_3(OH)N_2$. ephaeline and hydroipecamine contain a phenolic and the other three alkaloids an alcoholic hydroxy group. Emetine cannot easily be purified by means of its hydrochloride, but its hydrobromide can easily be obtained pure, and should be preferred to any other emetine preparation for medicinal purposes. The proportions of the different alkaloids found in various commercial kinds of ipecacuanha (air-dried) are shown in the following table:—

	Minas.		Matto Grosso	Johore	Carthagena.	
	1	2			1	2
	%	%	%	%	%	%
Emetine	1·31	1·00	1·62	1·03	0·61	1·13
Ipecamine and hydroipecamine	0·53	0·36	0·53	0·25	0·22	0·32
Cephaeline	0·60	0·62	0·52	0·46	0·74	0·81
Psychotrine.........	0·06	0·05	0·06	0·04	0·05	0·06
Total	2·50	2·03	2·73	1·78	1·66	2·32

All of the ipecacuanha alkaloids give a yellow colour reaction with bleaching powder in presence of acid. Emetine, cephaeline and psychotrine dissolve to a colourless and ipecamine and hydroipecamine to a faintly yellowish solution in sulphuric acid of sp. gr. 1·84. On adding a sulphuric acid solution of ammonium molybdate to this solution, emetine gives an emerald-green colour, persistent for several hours, cephaeline gives a brownish-red changing to blue and green and fading in a few hours, psychotrine gives quickly a green coloration, and ipecamine and hydroipecamine gradually a faint olive-green. The reactions are due to reduction of the molybdic acid. A similar reducing action of the alkaloids is the cause of the reaction with potassium ferricyanide and ferric chloride (Allen and Scott-Smith, this J., 1902, 1475).—A. S.

Cinchotoxine; Combination of bromine with ——. G. Rohde and S. Meissner. Ber., 1914, **47**, 1507—1515.

Cinchotoxine dissolved in hydrobromic acid was treated with a solution of bromine in the same acid at 0° C., when wo salts of the composition, $C_{19}H_{22}N_2OBr_2,2HBr$, were produced, which were separated by crystallising from dilute hydrobromic acid. One of these was white and melted at 151° C. when anhydrous. The other was yellow and melted at 162° C. in the anhydrous condition. Both salts were converted into basic salts, $C_{19}H_{22}N_2OBr_2,HBr$, by treatment with pyridine or the calculated amount of sodium carbonate solution. The basic salt obtained from the yellow dihydrobromide was white and melted at 178° C., whilst that from the white hydrobromide melted at about 168° C. The base corresponding to the latter was obtained by treatment with excess of sodium carbonate solution. It was bitertiary as a result of inner alkylation, and crystallised from benzene in rhombohedral crystals, m. pt. 124°—125° C. When the yellow dihydrobromide was treated with excess of sodium carbonate solution, cinchotoxine dibromide was produced, melting at 105° C. after crystallising from ether. When the solution of this base in benzene was boiled, or the chloroform solution was allowed to stand, the basic salt of m. pt. 178° C. was formed.—F. Shdn.

Galega officinalis; An alkaloid from ——. G. Tanret. Comptes rend., 1914, **158**, 1182—1184.

The seeds of *Galega officinalis* were extracted with 60 % alcohol and the extract purified by means of lead acetate and barium hydroxide. The alkaloid was finally separated as the sulphate, $(C_6H_{13}N_3)_2H_2SO_4$, crystallising in fine white needles, m. pt. 227° C. (Maquenne block), and optically inactive. The yield was about 0·5 %. The free base was very hygroscopic and soluble in water but insoluble in ether and chloroform. When crystalline it melted at 60°—65° C. The picrate was prepared by the addition of picric acid to the solution of the sulphate and melted at 180° C.—F. Shdn.

Aporeine and its salts. V. Pavesi. Gaz. chim. ital., 1914, **44**, I., 398—405.

The yield of alkaloids from *Papaver dubium* is much higher if the fresh material be extracted with alcohol than if the dried material be used as described previously (this J., 1907, 1108). Petroleum ether (b. pt. 45°—50° C.) dissolves 11 % of aporeine at the boiling point and only about 3·5 % at 15°—20° C., and the alkaloid can be crystallised from the hot supersaturated solution. It melts at 88°—89° C. (corr.) to a greenish yellow fluorescent liquid, which decomposes when heated in the air but can be distilled in a current of an inert gas such as hydrogen or carbon dioxide. Aporeine is dextro-rotatory, $[\alpha]^{15} = +75·19$ in 95 % alcohol. The petroleum ether extract of the crude alkaloid contains, besides aporeine, a small quantity of another alkaloid, m. pt. 176°—178° C., somewhat less soluble in this solvent. Aporeidine described previously (*loc. cit.*) as an alkaloid accompanying aporeine, is really produced by the action of light and air on the latter or on some other constituent of the crude alkaloid.—A. S.

Homonataloïn and nataloïn; Optical isomerides of ——, and their reciprocal transformation. E. Léger. Comptes rend., 1914, **158**, 1189—1191. (See this J., 1914, 275.)

When the β, γ- and δ-homonataloïns and nataloïns were heated to 105°—110° C. with acetic anhydride and sodium acetate, each yielded a mixture of three acetyl compounds exactly similar to those furnished by the natural aloins. —F. Shdn.

Emetine. I. A. Windaus and L. Hermanns. Ber., 1914, **47**, 1470—1472.

After energetic oxidation with potassium permanganate in aqueous solution, emetine hydrochloride yielded *m*-hemipinic acid and *m*-hemipinicimide.—F. Shdn.

Vanilla in Madagascar; Cultivation of ——. A. Fauchère. J. d'Agric. Trop.; Perfum. and Essent. Oil Rec., 1914, **5**, 152—153.

The variety cultivated in Madagascar is *Vanilla planifolia* introduced from Mexico 40 years ago. It flourishes best on granitic alluvial soil rich in phosphates and potash, in shady situations and with a humid climate. Propagation takes place by means of cuttings which yield a crop in about three years. Fertilisation is done by hand. The ripe pods after gathering are immersed in boiling water for 15—20 seconds, drained, and placed on woollen cloths. They are then exposed to the sun during the day and wrapped up at night for 4—10 days, when they develop a chocolate colour. Drying is effected by laying the pods on open shelves for several weeks. In 1911 the production of vanilla in Madagascar was 52,430 kilos. and in 1912 113,662 kilos. The yield may vary from 600 to 1000 kilos. of green pods per hectare (500—900 lb. per acre).—F. Shdn.

Vanillin; Reactions of ——. E. P. Häussler. Z. anal. Chem., 1914, **53**, 363—371.

Aqueous alcoholic solutions of vanillin when evaporated in an open dish on the water-bath with various organic substances in presence of a little dilute hydrochloric or sulphuric acid yielded very characteristic colour-reactions. Thus, amines, imines and amides gave a yellow and phenols a red or violet coloration. In many cases the subsequent addition of ammonia effected a change or disappearance of the colour. Blank experiments should always be made with the substance in the absence of vanillin before applying such tests. By means of p-phenylenediamine hydrochloride (pink colour) or phloroglucinol (yellow colour) it was possible to detect, respectively, 5×10^{-7} grm. or 5×10^{-6} grm. of vanillin. —J. R.

Tobacco; Chemistry of ——. *The essential oil of tobacco.* W. Halle and E. Pribram. Ber., 1914, **47**, 1394—1398.

An essential oil was isolated from the extract obtained from tobacco by means of warm organic solvents, the yield being 0·047% of the original weight of tobacco. The oil, which had an acid reaction, was treated with sodium carbonate solution and fractionated by distillation which took place between 77° and 133° C. at 26—22 mm. As the fractions developed acidity they were again treated with sodium carbonate, distilled, and their characters determined. There was finally obtained from the lower fractions a hydrocarbon, $C_{10}H_{18}$ or $C_{11}H_{20}$, b. pt. 73°—76° C. at 20 mm. On oxidation with permanganate this yielded terephthalic and isobutylacetic acids. A small quantity of isovaleric acid was separated from the sodium carbonate solution used in treating the original oil.—F. Shdn.

Malt extract; Laboratory studies on ——. H. T. Graber. J. Ind. Eng. Chem., 1914, **6**, 403—404.

Concentrated aqueous glycerin malt extracts darken in colour soon after manufacture and on keeping for a year or more acquire an acid taste and disagreeable odour. Extracts of ages varying from 3 to 12 months were found not to have suffered any diminution of diastatic activity. On keeping for longer periods, however, increasing quantities of lactic acid were formed, and when more than 1% was present, the diastatic activity was considerably weakened. The darkening of the extracts is also attributed to lactic acid.—A. S.

Digestive ferments; Assay of ——. H. T. Graber. J. Ind. Eng. Chem., 1914, **6**, 402—403.

To obtain uniform results in the determination of the diastatic power of pancreatin preparations the starch used should be neutral or very slightly acid to cochineal indicator and the moisture content should not vary greatly. The diluted iodine solution should always be at the same temperature when used.—A. S.

Lavender oil with high ester content. J. C. Umney. Perfum. and Essent. Oil Rec., 1914, **5**, 130.

Oil distilled in April from lavender grown at an altitude of 900 metres in Dalmatia had the following characters: sp. gr. 0·899, optical rotation—8° 30′, esters 61·6%, solubility in 70% alcohol 1 in 4. Oil obtained a year ago from plants grown at the same altitude had an ester percentage of 57·1 as against 43 and 49 for oils distilled from plants grown at 250 and 500 metres respectively. —F. Shdn.

Salol, sulphonal and β-naphthol; Incompatibility of —— [*in pharmaceutical preparations*]. G. Bianchini. Atti R. Accad. dei Lincei, Roma, 1914, **23**, I., 608—615.

Binary and ternary mixtures of salol, sulphonal and β-naphthol were examined by the method of thermal analysis. From fused binary mixtures of sulphonal and β-naphthol and of salol and sulphonal the pure components separate. The sulphonal-β-naphthol eutectic contains 62 mols. % of β-naphthol and melts at 67° C.; the salol-sulphonal eutectic contains 92 mols % of salol and melts at 34° C. In the case of fused mixtures of salol and β-naphthol, a solid solution separates from mixtures containing 80 mols. % or more of β-naphthol; the eutectic contains 85 mols. % of salol and melts at 34·5° C. In mixtures containing the three substances, together, the ternary eutectic melts at 27° C., and is composed of salol 78, β-naphthol 15, and sulphonal 7 mols. %. These results show that it is inadvisable to add sulphonal to mixtures of salol and β-naphthol which are to be packed up in paper or cardboard cases. (See also this J., 1913, 251.)—A. S.

1.3-*Butadiene hydrocarbons; New process for the preparation of* ——. *II. Pyrogenetic decomposition of hydroxy compounds. III. Catalytic dehydration of hydroxy compounds.* L. P. Kyriakides. J. Amer. Chem. Soc., 1914, **36**, 980—1007.

Glycols and unsaturated alcohols can be dehydrated to 1.3-butadiene hydrocarbons by catalysis over kaolin or aluminium phosphate, at temperatures above 350° C., preferably under diminished pressure. Thus β-butyleneglycol was converted into butadiene, the butanediol, $CH_3.CH(OH).CH(CH_3).CH_2OH$, into isoprene, and the pentanediol, $CH_3.CH(OH).CH_2.CH(OH).CH_3$, into piperylene. Ditertiary α-glycols, *e.g.* pinacone, can be dehydrated to 1.3-diolefines in presence of finely divided copper at temperatures above 430° C. The yields in most cases are good. Ditertiary, tertiary-secondary, and disecondary glycols, with the exception of the α-glycols in the last two cases, can be dehydrated to the corresponding 1.3-butadiene hydrocarbons by the catalytic action of small quantities of halogen acids, or their derivatives, particularly the halogen salts of aniline. The process is made continuous by boiling the glycol with the catalyst in a flask, allowing the hydrocarbon to distil off through a fractionating column as it is formed, and running in fresh glycol to take the place of that decomposed. In general hydrobromic acid or aniline hydrobromide were more efficient than hydrochloric acid, and produced a smaller amount of undesirable by-products. Pinacone with 0·2% of hydrobromic acid or 1% of aniline hydrobromide was converted into 2.3-dimethyl-1.3-butadiene with a yield of over 70%. 2-Methyl-2.4-pentadiene, $(CH_3)_2C:CH.CH:CH_2$, was prepared from acetone by condensing it to $(CH_3)_2C(OH).CH_2.CO.CH_3$, reducing this to the glycol and dehydrating with hydrobromic acid; a 50% yield of the hydrocarbon was obtained, and the remainder consisted of the unsaturated alcohol, $(CH_3)_2C:CH.CH(OH).CH_3$, which, by repeating the treatment was eventually entirely dehydrated to the methyl pentadiene. This new hydrocarbon was polymerised by the sodium process to a caoutchouc-like substance. Other unsaturated alcohols, similar to the above, were likewise quantitatively dehydrated, isoprene being obtained, for example, from $(CH_3)_2C(OH).CH:CH_2$. The method is also applicable to the dehydration of tertiary alcohols, thus trimethylethylene was readily obtained from dimethylethylcarbinol by heating with a small quantity of hydriodic acid or of aniline hydrobromide.—G. F. M.

Hydrogenation of liquids; Catalytic —— *under the influence of common metals, at moderate temperature and pressure.* A. Brochet. Comptes rend., 1914, **158**, 1351—1353.

In many cases, the hydrogenation of liquids may be effected by certain common metals, notably nickel, without recourse to high temperature or pressure, and in all cases a much lower temperature may be employed than that adopted in the method of Sabatier and Senderens. The proportion of nickel (obtained by reduction of the oxide at about 300° C.) may be as low as 0·1 to 0·5% of the weight of liquid in some cases. The method is applicable to the hydrogenation or reduction of various organic compounds. A mixture of the active metal and the liquid (the substance to be treated, or its solution or suspension in a suitable liquid) is agitated vigorously in presence of hydrogen at the ordinary or higher pressure. —L. E.

Nitroglycerin [*in pharmaceutical preparations*]*; Determination of* ——. F. W. Heyl and J. F. Staley. Amer. J. Pharm., 1914, **86,** 195—198.

The colorimetric method with phenoldisulphonic acid introduced by Scoville (this J., 1911, 1086) is more suitable for the estimation of minute quantities of nitroglycerin in tablets and other pharmaceutical products than the Kjeldahl method. Analyses by the two methods show close agreement.—O. E. M.

Formic acid; Method of determining ——. V. Hottenroth. Chem.-Zeit., 1914, **38,** 598.

The acid, which may be dissolved in a homologous acid or other indifferent solvent, is treated with acetic anhydride and a drop of concentrated sulphuric acid, as contact substance. There is an immediate evolution of carbon monoxide, in accordance with the equation,

$$(CH_3CO)_2O+H.CO_2H=2CH_3.CO_2H+CO,$$

and the evolved gas is measured. Water, if present, is removed by allowing an excess of acetic anhydride to react before adding the sulphuric acid.—F. Sodn.

Ethyl alcohol; Specific reaction for ——*; Method of identifying it in presence of aldehyde, acetone, methyl alcohol, etc.* A. Toninelli. Ann. Chim. Analyt., 1914, **19,** 169—170.

From 25 to 100 c.c. of the sample is distilled and the fractions between 60° and 80° C. collected in 2 c.c. portions. (Higher alcohols, if present, must be removed before distillation by treating the sample with a 5 per cent. solution of alum and shaking with a small quantity of benzene.) To each 2 c.c. of distillate are added 2 c.c. of iodine solution (12 grms. in 100 c.c. of ether), and after standing 2 mins., 4 c.c. of potassium hydroxide solution (40 grms. in 100 c.c. of water). When the solution is decolourised, 2 c.c. of a solution of 1.2.4-dinitrotoluene (1·5 grms. in 200 c.c. of a mixture of 1 part of carbon bisulphide and 2 parts of ether) are added with brisk agitation. In the presence of ethyl alcohol a play of colours is observed in the upper layer which eventually becomes an intense garnet red. The reaction will detect ethyl alcohol in the distillate at a dilution of 3 per cent., and is not affected by the presence of methyl alchol, acetone, or aldehyde.—G. F. M.

odine tincture; Regeneration of altered ——. F. Roques. J. Pharm. Chim., 1914, **9,** 277—288.

he free hydriodic acid present in altered tincture of odine may be readily decomposed, with regeneration of odine, by shaking for a few minutes with excess of finely ivided iodic acid.—F. Shdn.

Patents.

lkali salts of acidyl-ortho-[*hydr*]*oxyphenylcarboxylic acids; Manufacture of* ——. A. G. Bloxam, London. From J. A. Wülfing, Berlin. Eng. Pat. 9266, April 19, 1913.

he process described in Ger. Pat. 270,326 of 1913 (this J., 14, 439) is extended to include other alkali salts of all idyl-*o*-hydroxyphenylcarboxylic acids. Instead of using phatic esters for moistening the reaction mixture, an phatic alcohol or ketone may be used.—T. F. B.

Ether recovery during the evaporation of ethereal solutions of tannin and other similar solutions; Process for ——. Nitritfabrik Akt.-Ges. Fr. Pat. 465,835, Dec. 6, 1913. Under Int. Conv., Jan. 28, 1913.

The ethereal solution is subjected to suction in a closed chamber, and the mixture of air (or other inert gas) and ether vapour drawn off is led to a refrigerator where part of the ether condenses. The air is afterwards heated and returned to the evaporating chamber. F. Shdn.

Perfumes in enfleurage with fatty bodies; Process for the removal of ——. Lautier Fils. Fr. Pat. 465,941, Sept. 24, 1913.

The perfumes adhering to the fatty base obtained in the enfleurage process are removed by exhaustion (suction). —F. Shdn.

Essential oils, perfumes, etc.; Process for the extraction of ——. J. A. Meunier. Fr. Pat. 466,273, Feb. 26, 1913.

The extraction is carried out by means of steam under reduced pressure in a closed apparatus. For instance, in order to purify oil of almonds, the oil is placed with water in a vessel connected with a condenser and receiver. After exhausting the whole arrangement by means of a pump the vessel is heated. As soon as boiling takes place, the pump is disconnected and the distillation allowed to proceed.—F. Shdn.

Pancreatic extracts; Stable —— *for industrial use.* Lepetit Dollfus & Gansser. Fr. Pat. 466,276, May 29, 1913.

The pancreatic glands are mixed with an equal volume of sugar and the whole disintegrated. The product becomes homogeneous after standing for several days. —F. Shdn.

Dimethylaminooxymethane and dimethylamine; Manufacture of ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 14,493, June 23, 1913.

See Fr. Pat. 460,429 of 1913; this J., 1914, 42.—T. F. B.

Acetylsalicylic acid; Preparing salts of ——. O. Gerngross, Berlin, and H. Kast, Frankfort on Maine, Germany. Eng. Pat. 18,743, Aug. 18, 1913. Under Int. Conv., Oct. 11, 1912.

See Fr. Pat. 464,081 of 1913; this J., 1914, 439.—T. F. B.

Benzyl alcohol; Manufacture of ——. F. W. Klever, Cologne, Germany. Eng. Pat. 20,505, Sept. 10, 1913. Under Int. Conv., Sept. 11, 1912.

See Fr. Pat. 462,438 of 1913; this J., 1914, 277.—T. F. B.

Ketobases and ketodiamines of the formula, $CH_3.CO.CH(R).CH_2.N(R')_2$ and $CH_3.CO.C(R)[CH_2N(R')_2]_2$ *(R=hydrogen or alkyl, R=alkyl); Process for producing* ——. Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 25,410, Nov. 6, 1913. Under Int. Conv., Nov. 7, 1912. Addition to Eng. Pats. 25,963 of 1912 and 14,231 of 1913.

See Ger. Pat. 267,347 of 1912; this J., 1914, 103.—T. F. B.

Amino- and diamino-ketones; Process for preparing aliphatic ——. Farbenfabr. vorm. F. Bayer und Co. Second Addition dated Nov. 3, 1913, to Fr. Pat. 454,543, Oct. 28, 1912. Under Int. Conv., Nov. 7, 1912.

See Ger. Pat. 267,347 of 1912; this J., 1914, 103.—T. F. B.

1.3-*Butylene-glycol; Process of producing* ——. K. Delbrück and K. Meisenburg, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,094,539, April 28, 1914.

See Eng. Pat. 940 of 1913; this J., 1913, 550.—T. F. B.

Isoprene ; Production of ——. A. Heinemann, London. U.S. Pat. 1,095,395, May 5, 1914.

See Eng. Pats. 14,030 and 24,236 of 1910 ; this J., 1911, 909.—T. F. B.

Lactid ; Manufacture of ——. R. Grüter, Charlottenburg, and H. Pohl, Biebrich, Assignors to Chem. Werke vorm. Dr. H. Byk, Lehnitz-Nordbahn, Germany. U.S. Pat. 1,095,205, May 5, 1914.

See Fr. Pat. 456,824 of 1913 ; this J., 1913, 1086.—T. F. B.

Bismuth salt of gallocarboxylic acid. R. Berendes, Elberfeld, Germany, Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,095,618, May 5, 1914.

See Ger. Pat. 268,932 of 1912 ; this J., 1914, 277.—T. F. B.

Fatty acids containing arsenic and phosphorus ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. First Addition, dated Nov. 21, 1913, to Fr. Pat. 449,014, Oct. 3, 1912. Under Int. Conv., Dec. 27, 1912, Jan. 2, Jan. 30, and March 25, 1913.

See Eng. Pats. 10,378 and 10,379 of 1913 and Ger. Pat. 271,158 ; this J., 1914, 218, 439, 503.—T. F. B.

Explosion of a cast iron benzene nitrating apparatus. Pikos. *See* III.

o-Nitro-p-diazonium-phenol and the constitution of the "diazo-phenols." Klemenc. *See* III.

Patents.

Dynamites ; Method of manufacturing safety ——. K. Ohno, Kitasui, Japan. Eng. Pat. 16,978, July 24, 1913. Under Int. Conv., Aug. 7, 1912.

Terpinene is used as a stabiliser. Examples given are : nitroglycerin (73 parts), terpinene (3) and kieselguhr (24 parts) ; and nitroglycerin (86—90 parts), nitrocellulose (6—10) and terpinene (3—4 parts).—G. W McD.

Smokeless powders ; Manufacture of ——. C. Claessen. Third Addition, dated Oct. 17, 1913, to Fr. Pat. 410,239, Dec. 11, 1909. (See this J., 1910, 842, 1239 ; 1911, 448.)

Nitrocellulose (70—80 parts) is gelatinised by a non-volatile nitro-compound, such as di- or trinitrotoluene (20—30 parts), without the aid of a volatile solvent, to form a propellant.—G. W. McD.

Explosive. G. A. Rauzières. Fr. Pat. 465,718, Dec. 1, 1913.

A mixture of potassium chlorate (90 parts) and barium nitrate (10 parts) thoroughly moistened with nitrotoluene. —G. W. McD.

Explosive ; Manufacture of a plastic ——. C. V. A. Herlin. Fr. Pat. 465,771, Dec. 5, 1913. Under Int. Conv., April 14, 1913.

An eutectic mixture of nitroglycerin and a nitrohydrocarbon or mixture of nitrohydrocarbons is used as basis of the explosives. Suitable proportions are comprised within the limits : nitroglycerin (10—20 parts), *o*-nitrotoluene (10—20), nitrobenzene (0—5), together with nitrocellulose (0·5—2·5), sodium nitrate (25—35), ammonium perchlorate (35—45), and woodmeal (0—5 parts). —G. W. McD.

Signal-fusee ; Time-burning railway ——. L. S. Ross, Newtonville, Mass., Assignor to Central Railway Signal Co., Pittsburgh, Pa. U.S. Pat. 1,094,596, April 28, 1914.

A mixture of a metallic nitrate, sulphur, a hydrocarbon, carbon, potassium perchlorate and potassium chlorate, the last not exceeding 5%.—G. W. McD.

Explosive. A. Voigt, Giessen, Germany. U.S. Pat. 1,095,302, May 5, 1914.

See Fr. Pat. 425,550 of 1911 ; this J., 1911, 926.—T. F. B.

XXIII.—ANALYTICAL PROCESSES.

Thermometer (variable zero), with automatic setting of, M. J. Ruelle ; Report on ——. C. Féry. Bull. Soc. d'Encour., 1914, 121, 405—408.

The quantity of mercury in a delicate thermometer with a variable zero may be easily and exactly regulated by means of the arrangement shown in the figures. The bulb is first warmed till the whole thread is filled as in Fig. 1. The thermometer is then temporarily inverted so that the mercury in the reservoir retains the position shown in Fig. 2, on reverting to the normal position. The temperature of the bulb is then brought to a value equal to the desired zero of the instrument plus a constant which depends on the length ol the capillary and which is marked on each instrument. When the bath has reached this temperature, the thermometer is given a light ta which causes the mercur to fall again and cuts it of from the capillary. Fo very precise use it is o course necessary to hav the value of the degrees o the instrument calibrate for different values of th zero, *i.e.*, for different quantities of mercury in th bulb.—W. H. P.

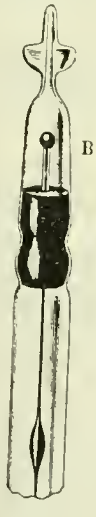

Fig. 1.

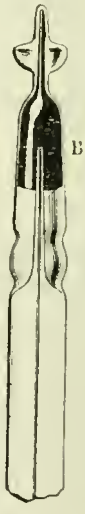

Fig. 2.

Cobalt, nickel, iron, and copper ; Colorimetric determinati of ——. C. Hüttner. Z. anorg. Chem., 1914, 8 341—357.

The colours of chloride solutions in concentrated hydr chloric acid, are matched against those of similar standa solutions of the metal concerned. Cobalt (above 0·1 may be readily detected in nickel or its alloys by the gre tint which it imparts to the otherwise yellow solutio the colour allows of the determination of up to 10% For the determination of iron or copper, the solution shou contain not more than 1 grm. of metal in 10,000 c.c the depth of tint (intense yellow) is influenced by the co centration of the acid. No loss of metal was observed evaporating solutions containing iron with hydrochlo acid on the water bath, and the presence of manganese a small proportion of cobalt or nickel had no disturb effect in the determination of iron. In all cases, nit acid and oxides of nitrogen should be avoided and t chlorine must not be present in determining cobalt. The application of the method to the analysis of commercially pure metals is described. The yellow colour of commercial hydrochloric acid was found to be due chiefly to iron (about 0·03 grm. per litre). —F. SODN.

Titanium; Separation of —— from iron, aluminium and phosphoric acid by means of the ammonium salt of nitrosophenylhydroxylamine ("cupferron"). W. M. Thornton, jun. Amer. J. Sci., 1914, **37**, 407—414. (See also this J., 1914, 279.)

THE solution (about 100 c.c.) is treated with sufficient tartaric acid (at least 4 times the total weight of the four oxides) to prevent precipitation by ammonia, then neutralised with ammonia, acidified with 2 c.c. of sulphuric acid (1 : 1), and the iron reduced by hydrogen sulphide. An excess of ammonia is then added; the ferrous sulphide is filtered off and well washed with water containing ammonium sulphide. The filtrate is acidified with 40 c.c. of sulphuric acid (1 : 1), the hydrogen sulphide boiled off, the solution cooled, diluted to 400 c.c., and a 6% solution of "cupferron" added slowly with constant stirring. The precipitate is allowed to settle and the supernatant liquid tested with a few drops of the reagent. The formation of a yellow turbidity shows the precipitation to be incomplete. The precipitate is filtered off and washed 20 times with dilute hydrochloric acid (1 : 10), the filter placed in a tared platinum crucible, dried at 110° C., ignited very gently at first, then over the blowpipe to constant weight and the residue weighed as TiO_2
—W. R. S.

Beryllium and uranium; Separation [and determination] of ——. M. Wunder and P. Wenger. Z. anal. Chem., 1914, **53**, 371—374.

A SOLUTION containing a mixture of beryllium and uranium chlorides or of beryllium chloride and uranium nitrate was treated with 3% hydrogen peroxide (10 c.c. for 0·16 grm. U_3O_8) on the water-bath. The yellow uranium precipitate was collected on a "double barium filter," washed with dilute hydrogen peroxide or dilute ammonium nitrate solution, ignited in a platinum crucible till the weight became constant and weighed as U_3O_8. The excess of oxygen was expelled from the filtrate by boiling and the beryllium precipitated with ammonia. The precipitate was collected, washed, ignited and weighed as BeO. The results were very accurate. In the presence of a large excess of beryllium the precipitation with hydrogen peroxide should be repeated, as the first precipitate is liable to be contaminated with beryllium.
—J. R.

Sulphurous acid; Volumetric determination of free ——. E. Kedesdy. Chem.-Zeit., 1914, **38**, 601—602.

THE determination of free sulphurous acid in the presence of other mineral acids could not be satisfactorily effected by titration with N/10 caustic alkali, using methyl orange to bisulphite), and phenolphthalein (to neutral salt), as ndicators, as the latter developed colour but slowly nd appeared to be "bleached." When excess of hydrogen eroxide was added after the first titration a sharp colour hange was obtained in the second stage with phenolhthalein. (See also this J., 1914, 442.)—J. L. F.

jeldahl method [of determining nitrogen]; A new modification of the ——. L. Marino and F. Gonnelli. Atti R. Accad. dei Lincei, Roma, 1914, **23**, I., 523—530.

ANADIUM pentoxide, obtained by igniting ammonium etavanadate, is used as catalyst. One grm. of subance is heated with 20—35 c.c. of concentrated sulphuric id, 7 grms. of potassium sulphate, and 0·2 grm. of nadium pentoxide until the colour of the solution anges to emerald green; then 0·2 grm. more of vanadium ntoxide is added, the mixture is heated for ½ hour nger, and the determination completed as usual.—A. PATENTS.

Gas-analysis apparatus. E. J. Billings, Assignor to A. D. Little (Incorpd.), Boston, Mass. U.S. Pat. 1,089,390, March 10, 1914.

THE apparatus, of the Orsat type, is provided with means for continuous sampling at predetermined rates. The sampling pipette is connected with an inlet from the flue fitted with a filter for the removal of soot, and with an outlet leading to an aspirator, by means of which flue gases are drawn continuously through the pipette. The upper part of the pipette contains a water-sealed outlet connected through stop-cocks with a sampling tube which is initially filled with mercury. The mercury is allowed to flow from the sampling tube at any desired rate by means of an overflow device connected to the lower end by flexible tubing and lowered gradually by clockwork, thus drawing gases from the sampling pipette into the sampling tube.—A. T. L.

Calorific value of fuels ; Process and apparatus for measuring the ——. H. Junkers. Fr. Pat. 466,280, Oct. 9, 1913. Under Int. Conv., Oct. 16, 1912.

See Eng. Pat. 22,514 of 1913 ; this J., 1914, 105.—T. F. B.

XXIV.—MISCELLANEOUS ABSTRACTS.

Germanium from Vichy water ; Extraction of ——. J. Bardet. Comptes rend., 1914, **158**, 1278—1280.

The residues from the preparation of Vichy salts were heated with water, and the precipitate treated with hydrogen sulphide under special conditions, when a solution of germanium was finally obtained. A yield of 0·060 grm. of pure oxide was obtained from 100 kilos. of the above precipitate, representing 250,000 litres of the mineral water.—F. Shdn.

Butine [Ethylacetylene] ; Preparation of pure ——. M. Picon. Comptes rend., 1914, **158**, 1184—1187. (See this J., 1913, 818.)

Ethyl chloride, bromide or iodide was allowed to act upon a solution of monosodium-acetylene in liquid ammonia. With ethyl iodide reaction took place at —40° C. The gaseous products of the reaction were washed with water and dilute sulphuric acid, dried, and liquefied by cooling to —80° C. Acetylene was removed by exposing the liquid at this temperature to a vacuum. The pure ethylacetylene had an onion-like but slightly ethereal smell and a sweetish taste. It boiled at 8·3° C. at ordinary pressure and after solidification formed a crystalline mass melting at —137° C.
—F. Shdn.

Book Received.

Lehrbuch der Farbenchemie, einschliesslich der Gewinnung und Verarbeitung des Teers sowie der Methoden zur Darstellung der Vor- und Zwischenprodukte. Von Dr. Hans Th. Bucherer, Direktor der Chemischen Fabrik auf Actien (Vorm. E. Schering) in Berlin, Ordentl. Professor a. d. der Technischen Hochschule in Dresden. Otto Spamer's Verlag in Leipzig. 1914. Price M. 20 ; geb. M. 22.

Volume (9½ by 7 ins.), containing 537 pages of subject matter, and an alphabetical index of subjects. The text is classified as follows :—I. Coal tar, its recovery and working up. II. Intermediate products of coal tar distillation. III. The dyestuffs. IV. (i), Theoretical considerations on the connection between colour and constitution. (ii), Introductory remarks on the behaviour of the dyestuffs in dyeing (Methods of dyeing). (iii) Synthetic methods for preparing the coal tar colours. (iv) Natural colours.

A TABLE OF SPECIFIC GRAVITIES OF SPIRITS CORRESPONDING TO INDICATIONS OF GLASS HYDROMETERS FOR USE WITH BEDFORD'S CORRECTED SIKES' TABLES.

BY JITENDRA NATH RAKSHIT AND SACHINDRA NATH SINHA, M.A.

(This Journal, March 31, pp. 288—289.)

This paper has been withdrawn by the authors and is cancelled.

New York Section.

Meeting held at Chemists' Building on Friday, May 22nd, 1914.

MR. G. W. THOMPSON IN THE CHAIR.

REFRACTORY MATERIALS.

BY GILBERT RIGG.

The subject of refractory materials to-day presents an enormous field for study. Clay is only one of many heat resisting materials now in regular use. Silica, bauxite, chromite, graphite, carborundum, etc., etc., are all finding increasing application in many directions.

To deal with anything like completeness with such a wide and varied range of material is obviously far beyond the possibilities of a paper like the present one. I propose, therefore, to confine my remarks mainly to refractories composed of clay, and to discuss certain features in the structure and composition of these bodies which I have found to be important factors in their usefulness and durability. Also I wish briefly to draw attention to certain methods of testing which have been shown to give useful indications.

My attitude towards this subject is that of a metallurgist principally concerned with the treatment of zinc ores, and my study of refractories has been influenced by the requirements of this industry. In this connection, I have found that certain types of structure are advantageous, and have worked out certain tests which have proved useful in the identification and standardising of these types. I have also attempted to get at the principles which underlie the empirical relations found between structure, durability and general appropriateness to the purpose in hand.

The following properties are all factors which together condition the utility and durability of firebrick :—1. Refractoriness. 2. Grain and compactness. 3. Burn-

4. Porosity. 5. Resistance to penetration, corrosion and chemical change. 6. Truth of surface and dimensions. 7. Conductivity.

(1) *Refractoriness.*—In ordinary furnace practice failure of firebrick through actual fusion is one of the rarest cases. The materials which enter into the body of high-class refractory material usually possess a melting point well in excess of the temperatures met with in furnaces heated by fuel. In electric furnaces, of course, conditions may readily arise which will cause the real fusion of the brick.

In some cases, however, distinct softening may occur, without actual fusion. When the bricks are built into a solid mass of masonry as in a furnace wall, this is hardly likely to cause serious trouble unless very marked. Where, on the other hand, the brick is supported only at the ends, as in the case of a shelf, it will be not unlikely to sag, especially if loaded in the middle. This condition is frequently due to small quantities of fluxes in the clay, which are not sufficiently large to cause actual fusion, but are large enough to bring about a slightly viscous condition, which allows the brick to yield gradually.

It will usually show up more quickly in a brick whose constituents have been finely ground and closely pressed together than in a coarse, loose textured one. In the latter case, however, the trouble is only postponed, unless, indeed, the inherent weakness of such brick causes failure by fracture before softening has time to appear. .

It has been shown by Ries and others that the fineness to which the different constituents of a firebrick have been ground has a strong influence on the point of fusion or softening point; the finer the constituents are ground the lower is the melting point. By grinding a firebrick to powder (100 mesh) and forming the powder into three sided pyramids, like Seger cones, and exposing these to temperature of 100° C. above that at which the brick will have to work, we have a good accelerated test. If the cones stand up under this discipline, the brick will withstand the conditions of service as far as heat alone is concerned.

The resistance to heat due to coarseness of grain and the looseness of texture that goes with it, cannot be considered as permanent. The action of the fluxes still continues, but more slowly, and the brick gives gradually. When destructive vapours or slags are present these soon penetrate a loose textured brick and destroy it.

Where the bricks are exposed to the action of a fusible dust, at a high temperature, as in the case of a firebox in which coal with a low fusion point ash is being burned, apparent fusion, due to the deposition and fusion of the coal ash on the firebrick of the arch, is quite common. This is strictly a case of corrosion and will be dealt with more fully under this head.

(2) *Grain and compactness.*—This subject is one about which some difference of opinion seems to exist. A plastic clay, when worked down with water until its plasticity is thoroughly developed, will after drying and burning yield a fairly homogeneous mass (as far as its solid substance is concerned). In the large majority of cases, however, such clays are unsuited to the production of firebrick when used alone, as the large amount of water taken up by the clay causes excessive shrinkage during drying and burning, and in consequence the bricks are badly cracked and deformed. To remedy this the plastic clay is usually mixed with a non-plastic material, either a non-plastic refractory clay, or with the plastic clay after the latter has been dried and burned. Bricks made in this way constitute a very large percentage of the fireclay refractories used in smelting and when well made give good results.

In the case of a brick made of, for example, 30% of a plastic clay and 70% of a non-plastic and highly refractory flint-clay, the question of what should be the ruling size of the grains of flint-clay is one of extreme importance.

There seems to be some disposition in the trade to regard with suspicion bricks made with a flint-clay or burnt clay (or "grog," as it is commonly called), which has been crushed through an 8-mesh screen, on account of the risk of cracking or spalling with changes of temperature. I believe, however, that this risk has been greatly exaggerated, and I think that this view has been gaining ground considerably during the last few years. For example, a 9 in. brick has been kept at a temperature of 1400° C. for about 6 hours, and then withdrawn and allowed to cool quickly in the open air. The brick is a fine-grained one, fully as fine as the figure quoted, and yet this severe treatment has had no effect on it.

In another place I have made use of a parallel drawn between concrete and firebrick as a guide to the understanding of the physical structure of the latter. In both cases we begin with a collection of separate non-plastic solid fragments imbedded in a plastic mass. The latter subsequently hardens in the case of cement by setting, in the case of the brick by drying and burning, and the final state of both is that of a solid mass composed of grains set in a solid matrix.

The power of cohesion of many plastic clays after drying and burning is quite considerable, figures of 500—600 lb. per square inch being not uncommon. On the other hand, the shrinkage is considerable, and there is a great tendency for the plastic clay to open in minute fissures during burning, especially when the grog is coarse, ¼ in. pieces or over. This fissuring makes the brick weak and crumbling, and opens it up to the entry of destructive gases and slags (Fig. 1). I have found that if the grog be sized, as is done with the stone and sand in concrete, the density and strength of the bricks can be greatly improved, especially if the mass be thoroughly compressed before drying and burning.

In our own work we find that with the flint-clay or grog crushed through an 8 in. mesh screen we have never been troubled with spalling, and the bricks resist the penetration of gases, etc., much better than the coarse-grained masses, and resist also the disrupting adhesion of heavy masses of incrusting material forming on the lower surface of the arches far better.

As a general rule the non-plastic flint-clays are considerably more refractory than the plastic bond-clays. Moreover, as they are not required to exert any binding effect on the mass they can be calcined before use and their fire-shrinkage thereby eliminated, or at any rate greatly reduced. The bond-clay will naturally have considerable shrinkage, owing to the amount of water it has taken up, and, as stated above, it is usually less refractory than the flint.

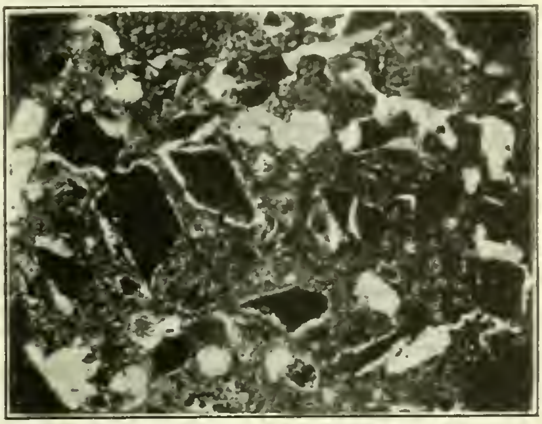

Fig. 1.

Obviously, then, it is essential to cut down the percentage of the bond-clay as low as possible when making up the brick, but if this is overdone the brick is, naturally, weak and crumbling and soon yields to penetration. If the bond-clay is excessive in amount, high porosity is likely to occur.

This is where regulation of the size of the grog comes in. By sizing the grog and then mixing the different sizes in the proper proportions, we have the minimum of space left to be filled up by the bond-clay, and can get the densest and closest mass with the least amount of bond; as stated above, it is very much like mixing concrete.

The question of machine-made *v.* handmade brick is closely tied up with the question of density. I prefer machine-made bricks. They are denser, truer to shape and freer from pores than the handmade. A well-made steam-pressed brick is, in my opinion, the best type of refractory on the market to-day.

The shapes that can be made by machine are much more limited in variety than those that can be made by hand. To engineers, who have to design furnaces, I would say—"Avoid as far as possible complicated shapes. Try to be a cubist. Use rectangular masses wherever possible, and try to keep one dimension as near to a 4½ in. maximum as the design will permit. By doing this you have a chance of getting your brick burned hard to the heart, whereas, if you have all three dimensions running high, it is very difficult to avoid underburning in the middle. As long as you keep your shapes simple you can get them machine made. It is not always possible to avoid complicated shapes, but the more you can do it the more chance the brick manufacturer has to give you satisfaction."

At the Chicago meeting of the American Iron and Steel Institute, held on October 24th, 1913, Mr. Harry W. Croft, President of the Harbison-Walker Refractories Company of Pittsburg, read a paper on "The Use and Development of Refractories in the Iron and Steel Industry," from which I will quote. The paper is an exceedingly interesting one, and the claims of machine-made or steam-pressed brick are done justice to, but the author still seems to have a warm place in his heart for the old hand-made brick.

"*Manufacture of fire clay brick.—Handmade brick.*—The clays mined and properly selected are broken into small lumps, mixed in suitable proportions and ground in the wet pan to the proper degree of fineness. The mass is then moulded into shape, tempered on a hot floor, repressed, thoroughly dried and burned at a temperature of 2600° to 2650° Fahrenheit. This is the old handmade process."

"This brick is open, porous and well adapted to withstand sudden changes of temperature. Many departures from this process have been tried and various machines employed in the different stages of manufacture. In many cases there has been a speedy return to the hand-made process, while in others a better brick has been developed for certain uses."

"*Machine made brick.*—In the high-grade brick, the most noticeable development in the machine-made product is in the manufacture of blast-furnace brick on a steam or other powerful press. The machine-made brick is denser by 7 to 8% than the hand-made one."

"*Uses of fire-clay brick—Blast furnace.*—The introduction of the water-cooled (blast) furnace, with its lining of 12 in. or less, necessitated the use of the highest grade of refractories available, and the blast-furnace operator and the brick manufacturer co-operated in making a brick of more uniform dimensions and of much greater density than heretofore, without sacrifice of refractoriness. This was accomplished by a mixture of clays giving the minimum of shrinkage and by manipulation designed to increase their bond to the maximum. The bricks were finally made into 12-in. blocks on a steam press. The result was a lining that fulfilled the expectations of all concerned."

"The furnace in which this lining was put was blown out after an eight months' run, to make some slight changes in the shell. The lining had taken on a thin coat of carbon which, when chipped off, exposed the face of the brick in many cases with the original skin intact. In making a 12-in. lining of such great density, backed by a water-cooled jacket, there was naturaly some apprehension as to whether it would spall. An examination showed that no spalling occurred. It also resisted the abrasion of the stock and channelling blast, and was practically impermeable to gases. A number of these linings have since been installed."

"At present blast-furnace men are calling for the hand-made and machine-made linings in about equal numbers. The present machine-made lining includes as many as possible of the good points of the first steam-pressed lining referred to, without all of the extra treatment of clays and consequent higher cost. In one point apparently the machine-made brick should be superior, and that is in furnace tops. It is also possible to make it of more regular and uniform dimensions than by the hand-made process, thus insuring better bricklaying."

"*Hot blast stoves.*—In hot blast stoves fire-bricks act merely as a thermal reservoir, yet are subject to widely varying temperatures, to enormous loads, and in many cases to the fluxing action of the flue dust in unwashed gases. Again we note development in the use of brick of greater density and higher refractoriness, with a decided tendency to substitute a higher for a lower gradebrick."

Mr. Ambrose N. Diehl, Superintendent of Blast Furnaces, Carnegie Steel Company, Duquesne, Pa., discussed Mr. Croft's paper from the blast-furnaceman's point of view, and some of his comments are very interesting and much to the point.

"*Machine and hand-pressed brick.*—There was formerly a prevalent opinion that hand-pressing of brick was a necessity, and that machine-pressing turned out a product which was not so durable. This feeling is passing, as the bricks made in machines have a better appearance and are truer to size, besides equalling if not exceeding the hand-pressed ones in durability. A comparison of a hand-pressed 9-in. brick with a 9-in. machine-pressed one made from the same material and manufactured in the same plant is given below. The machine-pressed brick was superior in shape and appearance."

"In examining the relative merits of machine-pressed and hand-pressed fire-brick certain determinations and simple tests are exhibited. First quality 9-in. fire-clay brick were taken as samples. As shown in the following tabulations the apparent specific gravities were compared. Those for hand-pressed brick were found to average 2·01 for five samples, and for steam-pressed brick 2·13 for five samples. Eight of these bricks were tested for spalling when chilled from high temperatures, but none showed any signs of chipping off, either when air cooled, when suddenly immersed in water, or when sprayed. One specimen of each being tested for absorption of water, it was found that each took up 4·12% of its volume or 6·02% by weight for the hand-pressed and 5·76% for the steam-pressed. By these tests it appears that the steam-pressed brick has a density 6% greater than the hand-pressed brick, and that it is just as capable of withstanding sudden changes in temperature."

"From our experience in handling brick in sheds for stock and rehandling for use, reports show a breakage loss of 50% less in the steam-pressed than the hand-pressed ones. This is also true regarding breakage in transit. Considerable money is thus saved to the consumer and the maker. For some purposes, such as irregular shapes, hand-made brick will always be preferable. The cost of laying the machine-made brick, due to its more perfect shape and less breakage in handling, will also be a great factor in its favour."

(3) *Burn.*—The question of "burn" belongs more to the manufacturing part of the subject of refractories. Naturally, the longer the time of burning and the higher the temperature, the more expensive the operation. From the consumer's point of view the burn should be carried far enough to bring out the full strength of the brick, and allow the fire-shrinkage to take place thoroughly.

There is, however, one point to which I would like to draw attention, and that is the burning of the grog or refractory non-plastic flint-clay before mixing with the plastic clay to form the brick. By doing this the fire-shrinkage of the flint-clay is eliminated altogether, and when severe conditions have to be withstood it is of undoubted advantage to do this.

The German Association of Firebrick Manufacturers has recently conducted a series of tests which show that the harder the material to be used for grog is fired, the better will be the quality of the finished brick. Lightly fired grog gives great shrinkage in the bricks.

The relation of dimension to burn has been referred to already.

(4) *Porosity.*—The porosity of a brick is usually determined by drying it, immersing it in water until its weight is constant, and reweighing it. The amount of water absorbed is a measure of the porosity of the brick. This test, however, unless care is taken to interpret it properly, may be exceedingly misleading. Strictly speaking, there is no objection to a brick containing empty spaces, so far as its heat-resisting properties are concerned. In fact, where the object is to retain heat, porosity is an advantage. When, however, the question of resistance to destructive gases, vapours and slags is concerned, porosity becomes of importance at once, and in judging a refractory it is necessary to know whether the openings are such as will admit these matters to the interior of a brick, or not.

Fig. 2 shows two bricks which have been immersed in a solution of glue, coloured by malachite green, for the same length of time, allowed to dry and broken across.

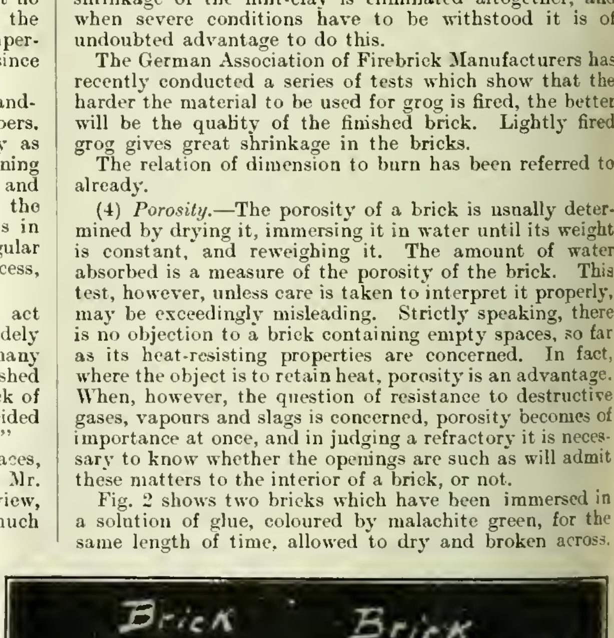

FIG. 2.

In one the glue has barely penetrated below the surface and the specimen appears white with a thin green selvage, showing somewhat deeper penetration at a few spots. In the other brick the glue has sunk well into the brick, somewhat irregularly, and its line of entry is in many places indicated by fissures stained green. Both these bricks would give a fairly high porosity test by the water method, but the behaviour of the two bricks towards a more viscous fluid like the glue solution, is radically distinct. Brick No. 1 is a strongly compressed, well-ground, rather fine-grained mass, the spaces in which are due simply to the evaporation of the water with which the plastic clay was made up and to the shrinkage on burning. Brick No. 2 is a coarse, loosely aggregated mass in which the percentage of bond-clay is insufficient to fill up the spaces between the pieces of grog. In the first case the viscous liquid refused to enter the brick ; in the latter it readily entered the coarser channels within the brick.

The result of this test agrees excellently with the behaviour of the two types in actual service. I shall go further into this branch of my subject when speaking of penetration. For the present I merely reiterate that all porosity tests must be checked by careful inspection of the mass, so that capillary pores which are relatively harmless may be distinguished from coarse openings which allow destructive agents to enter the brick. The glue test referred to above is a useful indication.

(5) *Resistance to penetration, corrosion, and chemical change generally.*—The subject of penetration and corrosion by gases and slags furnishes a series of problems in physical chemistry of a highly interesting order, both from the scientific and technical points of view. Penetration *per se* would be of little importance if unaccompanied by alteration of the clay. This, however, is very unusual. Almost all slags attack fire-clay more or less, and the attack proceeds with greater rapidity, if the corrosive influences can gain entrance into the interior of the refractory mass, than if they are confined to the surface.

In this connection, an item of considerable importance is the skin of the brick. When the plastic mass of clay and grog is submitted to pressure in the mould, the water is forced to the surface, carrying with it a little of the bond-clay. As the brick dries this latter is left on the surface, and during the burning it forms a dense layer over the brick, which forms the first line of defence. The resistance of this skin in a well-made brick is remarkable. In our work we find that it will block the penetration of oxide of zinc in the furnaces so completely that when the incrustation of this compound which forms on the lower surface of the arches is knocked away, or falls off with its own weight, the pattern of the brickwork shows up sharp and clear on the surface of the attachment of the mass. In poorly made brick, where the grains of flint-clay proper show through the skin, the mass of incrustation takes such firm hold of the irregular surface that pieces of brick are torn away when the mass comes down, and the arch is soon destroyed.

I should consider the absence of a good firm skin sufficient cause for rejecting a brick for our work. On the other hand, I should not consider a test for resistance to corrosion a fair one, unless it were carried out on the natural surface or skin of the brick. Tests on a fractured surface are for our purposes misleading.

Consider first the penetration of a brick by a liquid slag, supposing that the brick forms part of a furnace lining which is heated from within. The brick, therefore, will become progressively cooler away from the laboratory of the furnace. Let us further suppose that the brick is of a hard-pressed compact type, presenting only capillary openings. The liquid slag will proceed to enter the pores of the brick and attack the clay. As it absorbs the clay matter its freezing point rises until it solidifies, and in the case of a fine-grained brick the amount of slag that can enter is small and soon saturated. Under these circumstances a glaze forms on the brick, the slag penetrating for a quarter of an inch or so in capillary veinlets. The action will then go no further.

In the case of a brick which shows fissures and cracks the case is very different. The slag gets in at these points in considerable quantity, and by the time it has saturated itself with the clay it has eaten out a considerable hole. Into this more slag can get, and under such circumstances the brick is soon corroded away.

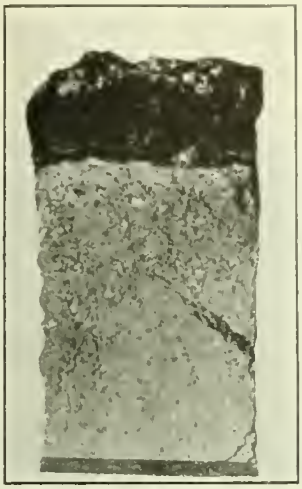

Fig. 3.

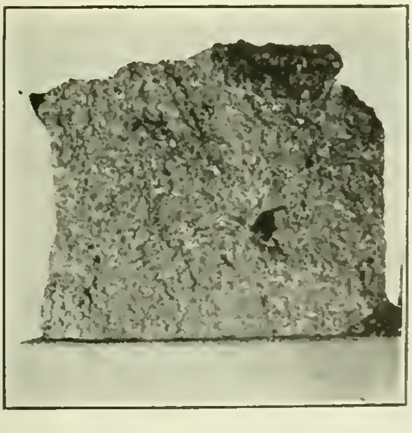

Fig. 4.

The photographs 3 and 4 show these two conditions well. In the first case the slag has failed to penetrate and forms a layer on the surface. In the second it has sunk in and destroyed the surface of the brick.

These considerations have led us to a method of testing which enables us to form a pretty good idea how a given brick will resist a specified slag within specified temperature limits.

A one-half 9 in. brick is a convenient size to handle, and it should be set up with one edge uppermost, as that is the surface which will probably be exposed in the furnace. The natural surface of the brick should always be tested as explained above. The slag, or slag constituents, should be ground to powder and made up into a block about 3 in. by $1\frac{1}{2}$ in. by 1 in. with a little starch, and dried. The slag block is then laid on the brick and the brick is placed in a furnace and brought up to about 100° C. above the working temperature. The slag block melts and flows down over the surface of the brick, attacking it on three faces.

The next two figures (6 and 7) are micro-photographs of a good brick before and after the test. The first one shows the pores with somewhat rounded contours, exaggerated by grinding. The latter shows the pores filled with slag.

An interesting example of the destructive effect of penetration was shown by determination of the melting points of certain refractory masses after various periods of exposure to a slag. After three months' service at a temperature of 1250° to 1350° C. it was found that the fusion point had fallen from 1700° to 1400° C. and failure came soon afterwards.

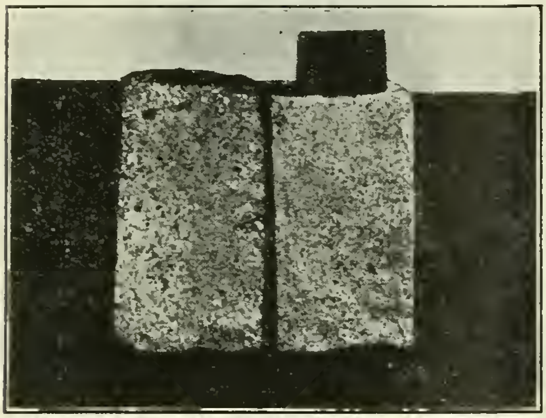

Fig. 5.

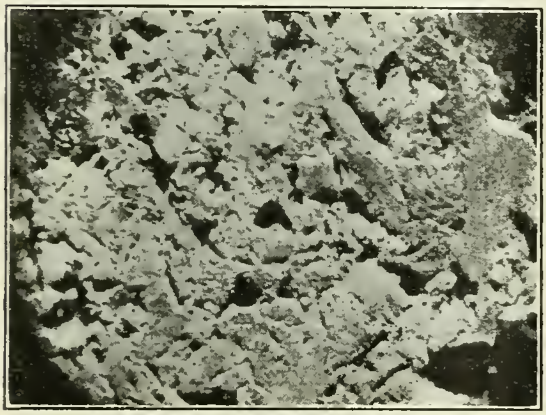

Fig. 6.

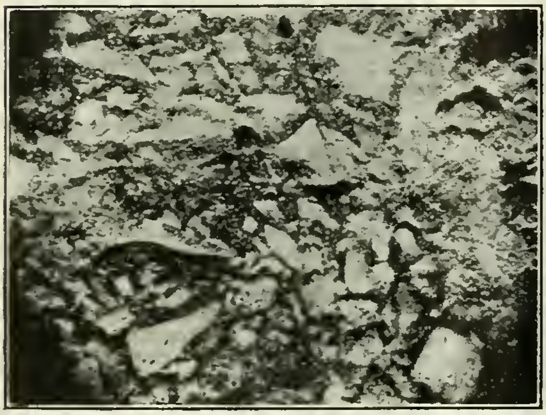

Fig. 7.

Another case is that of a loose-textured brick which has been immersed in molten spelter. The mass is completely impregnated with the metal as shown by the photomicrograph 8.

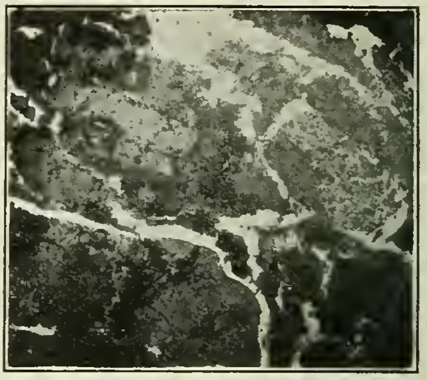

Fig. 8.

The changes that take place in the substance of a spelter retort, due to the action of zinc, constitute, perhaps, one of the most remarkable cases of chemical change in a working refractory known, because they take place at temperatures below the fusion point of the bodies entering into the reaction.

We find that after a spelter retort has been in service for some days it changes in colour from a light buff to a dark blue with white spots, and becomes a good deal denser. These changes are accompanied by a more or less complete chemical decomposition of the clay substance of the retort, the alumina of the clay combining with zinc oxide to form zinc spinel, $ZnO.Al_2O_3$, and the silica of the clay being liberated in the form of tridymite.

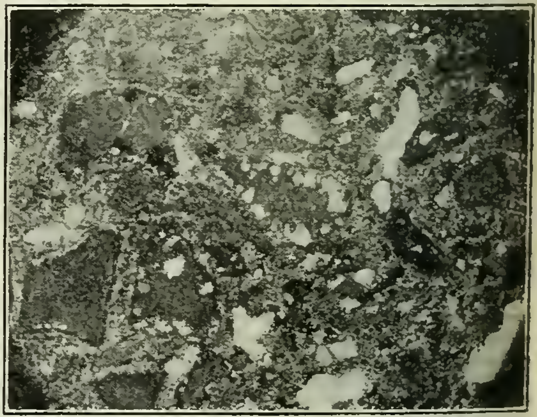

Fig. 9.

Figure 9 shows a micrograph taken from a slice of an old retort. The large grains are the grog, which being denser and more resistant than the bond are largely unaltered as yet. The granular matter is the zinc spinel, which occurs in grains or minute octahedra, and are seen forming fringes around the grog grains, showing that their decomposition is in progress.

In this case we have to deal with an actual change in the chemical composition of the refractory mass from a silicate of alumina to a mixture of zinc aluminate, or spinel, free silica and absorbed slag. Fortunately, however, this change is not accompanied by any deleterious results as far as the fitness of the retort for its particular purpose is concerned.

The longer my acquaintance with refractories becomes, the more I am convinced of the necessity that exists for the study of the relation of the charge to the furnace lining.

The behaviour of alumina in slags is a matter about which there is considerable difference of opinion. Mr. G. E. Johnson, jun., read a paper at the Cleveland meeting of the American Institute of Mining Engineers, in which he stated that he had seen a blast-furnace slag containing 30% of alumina running perfectly freely and giving no trouble. The general consensus of opinion, however, is that alumina causes slags to become viscous and difficult to tap, quantities as low as 6% being objectionable. This latter contention I can endorse from my own experience, mentioning also that I have also had experience of a 12% Al_2O_3 slag which behaved excellently. Of course part of the discrepancy might be explained as being due to differences of temperature, but this did not seem to be the whole of it, so I decided to investigate a little further.

The method used was to form the lime, silica, and alumina, which were all in powdered form, into a cube, with a trace of starch, the cube being formed around a spirally twisted Pt-Ir wire. The cube was about ⅝ in. a side, and was suspended in a crucible in an electric furnace provided with a pyrometer couple and the temperature brought up.

The first sign of fusion is the melting off of the corners of the cube. Shortly afterwards the cube rounds off and slips from the wire. A liquid mobile slag will be run off completely like water. A fairly stiff one will flow off slowly, leaving a thread drawn out behind it, whilst a very stiff one will draw into a pear-shaped mass and be very reluctant to leave the wire.

CaO. SiO₂.			2CaO.SiO₂.		
Al_2O_3%.	Fusion point.	Character.	Al_2O_3%.	Fusion point.	Character.
—	1460° C.	Stiff	—	1382° C.	Stiff
6·8	1318° C.	Fairly liquid	6·8	1422° C.	Very stiff
13·3	1296° C.	Very liquid	13·3	1468° C.	„ „
19·6	1272° C.	„ „	19·6	1453° C.	„ „

We experimented with a large number of mixes, and the results of one set are shown in the accompanying table. It will be noticed that with the metasilicate addition of Al_2O_3 brings down the melting point and liquefies the slag, whilst with the orthosilicate addition of alumina raises the melting point and stiffens the slag. This suggests a possible explanation for some of the differences of opinion referred to above.

Now, I have frequently heard it stated that heavy liming when blowing in a blast furnace tends to prevent scouring and cutting away of the lining, and my own experience confirms it, whilst the figures in the table suggest an explanation. With high lime, as the slag attacks the brick, the tendency will be to form a sticky, difficultly fusible, viscous glaze over the lining, which will collect a defensive covering of small coke, etc., whilst with low liming a thin, readily fusible slag will form, and scour the lining very efficiently.

(6) *Truth of surface and dimensions.*—The accuracy of the dimensions and surface of a brick is of great importance from the penetration point of view. When bricks are warped or untrue to dimension, necessitating wide courses, penetration is liable to occur. The clay grout which is used between the bricks is a poor substitute for brick and should be reduced to a minimum. It is an axiom amounting to a platitude that poor brick-laying, whether caused by lack of truth in the bricks themselves, or careless work on the part of the masons, is as bad for the furnace as a poor brick.

(7) *Conductivity.*—The factors which control the conductivity of refractory masses are getting to be better understood and I expect soon to see more authentic figures than any that are available to-day.

Conductivity appeals to the user in two different ways, according to whether it is required to retain heat inside the space enclosed by the brick or transmit heat through the brick. In the first case insulation is aimed at, and in the second case transmission.

Now, my own experience, and that of several others, indicates that a coarse-grained, loose-textured, porous mass makes for low conductivity, and a fine-grained, close-textured, compact mass, for high conductivity. The checker work in a blast furnace stove is a case in point. Here it is desired to absorb heat into the brick as quickly and completely as possible and return it to the air in the same way, and the tendency to-day is to go over more and more to dense and hard-burned brick for this purpose, as stated by Mr. Croft in the quotation given.

When the object is to retain heat, loosely compacted masses are more effective than close-textured ones. An extreme case of this condition I worked out some time ago. The questions at issue were: How many rings of brick would it be economical to place over a certain furnace arch in order to retain the heat, and what class of brick would be best? Or, could something more effective than brick be used? We started out with 1 in. thickness of firebrick in three rings. Under the third ring and on top of the furnace arch four thermo-couples were placed at different points, and the temperature was noted from day to day, until an average figure was obtained for the temperature on top of the furnace arch. Then the three rings were taken off and other materials were tried. Eventually we found the most economical material was boiler ashes screened through ¼ in. mesh: 3½ in. of this kept the top of the furnace arch as hot as 12 in. of fairly compact firebrick.

The lesson is fairly obvious, yet it is not uncommon to find figures published for the conductivity of firebrick without any mention being made of grind, burn, or porosity. Under these circumstances it is hardly surprising that the figures frequently do not check.

In Havard's book on Refractories and Furnaces the author draws attention to the necessity of knowledge of the burn-temperature of a brick in figuring on the conductivity. On page 280 Havard quotes a table of conductivities, giving amongst others the following relative conductivities:—

Magnesia brick	0·0074
Chromite brick	0·0057
Fire-clay brick	0·0042
Checker brick	0·0039
Gas-retort brick	0·0038
Silica brick	0·0020

Except for the statement that the figures selected are representative of the ordinary commercial grade of refractory materials, we are left in a good deal of doubt as to the nature and history of these samples.

In a later series we have the following:—

Magnesia brick	(burned at 1050)	0·0058
„ „	(burned at 1300)	0·0065
Chromite brick	(burned at 1300)	0·0034
Fire-clay brick	(burned at 1050)	0·0037
„ „	(burned at 1300)	0·0050
Checker brick	(burned)	0·0039
Silica brick	(burned at 1050)	0·0020
	(burned at 1300)	0·0031

These figures show considerable variation amongst themselves, but in general they show that the temperature of burning has a profound influence on the conductivity, particularly in fireclay-brick. I believe that compactness also plays a strong part. For example, the fire-clay brick that was burned at 1050° C. had a porosity of 30·8% of volume, and that burned at 1300° of 24·1%. It is a pity that bricks of a porosity of less than 10% were not tried. My own results suggest that they would have gone still higher.

This last group of figures is due to Wologdine, and is a great advance on anything preceding them, although I think the method used might be improved upon. The specimens tested were only 2 in. thick and were exposed only on one side to the heat. Under these circumstances the heat gradient would be exceedingly steep much more so than under working conditions.

Marshall, in a recent number of "Mechanical and Chemical Engineering," has challenged Wologdine's figure for silica brick, pointing out that these bricks are burned at a temperature considerably over 1300° C., and therefore that it is reasonable to suppose that the conductivity will be still higher.

I am strongly inclined to believe that compactness, grain, and temperature of burning have more to do with the conductivity of a refractory mass than its composition, within limits. Fire-clay and magnesite can be made to overlap, and so probably can fire-clay and silica. Under these circumstances figures like those first given are of little practical value.

In the discussion of Mr. Croft's paper Mr. Diehl concluded by saying that "refractories . . . demand an exhaustive and co-operative study from both the consumer's end, where new materials and progressive practices result in ever-changing demands on the refractory materials, and from the manufacturing end, where the proper material should be adjusted to meet the ever-changing conditions arising from such progression. By a clear understanding of the exact conditions to be met and the concerted efforts of both parties, there is no question but that the present assumed amortisation period can be greatly extended with benefit to all parties concerned."

I want to emphasise in the strongest possible way this need for co-operative study from both the consumer's end and the manufacturing end referred to by Mr. Diehl. If the manufacturers are to meet successfully the changing and increasingly severe conditions that refractories have to face to-day, co-operation on the part of the consumers is essential. When a lining fails, the dead lining needs careful study. Working temperatures, slags, gases, as far as possible every physical and chemical condition to which the bricks are exposed should be known, and the manufacturer fully acquainted with what his product has got to stand. We have tried to act up to this principle and have found that it pays. The more of us that play the game in this way, the easier it will be for us to get what we want, and the man who orders "fire-brick," and uses the contents of the resulting car indiscriminately on several different clases of work, will have himself to blame if the brick fails on some of them.

I believe that the interest in the subject is growing and that the outlook is decidedly hopeful.

SUBSTITUTES FOR AUTOMOBILE GASOLINE.

BY GAIL MERSEREAU.

During the last few years the development of the automobile and the greatly increased use of gasoline in chemical extraction work, combined with the partial exhaustion of the crude petroleums rich in gasoline, has more than doubled the cost value of this product.

During the last year or two there has been a great demand for some cheaper substitute for use in the automobile engine. The publication in the daily papers of offers of prizes for a solution of the problem has spurred on inventors to work out many ingenious possible solutions.

The Diesel type of engine is being used on some motor boats designed for racing and on some trucks, but can never find favour in the ordinary passenger automobile. This is because of the necessity of preheating the vaporiser. The ordinary user of the automobile will never take the trouble in order to save a few cents on his fuel.

Denatured alcohol can be used readily. It is clean, not so dangerous as gasoline, and will give three-fourths as much mileage as gasoline per gallon (and sometimes better); but it costs much more than gasoline and it hardly seems probable that the price will decrease greatly in the future.

Kerosene has been used and is being used more and more in heavy trucking. In order to use it in the ordinary motor it is simply necessary to heat the carburettor by means of the exhaust gases. The motor must be started with gasoline or alcohol. There is no difficulty in this, as it is easy to attach a small supplementary tank.

The great drawback to the use of kerosene is its production of polymerised products in the cylinder and the formation of coke and lampblack from these products. This polymerisation reaction takes place apparently only in the larger globules of the kerosene which enter the cylinder. The outside layer of oil is partially oxydised, with the formation of high boiling polymers. These then condense on the relatively cool sides of the cylinder. Further explosions in the cylinder oxidise and burn off more and more of the hydrogen atoms until the material becomes nearly pure carbon.

Alcohol, injected into the cylinders, while still hot, at the end of the day's work, will clean out the greater proportion of these troublesome products. This is too much trouble for the ordinary automobile owner.

To obviate the difficulties above mentioned, namely, the preheating of the carburettor and the production of coke and lampblack, a great many mixtures have been proposed.

All kinds of low boiling point constituents have been added, so that the carburettor need not be preheated, and all kinds of oxygen containing materials have been added to prevent the dehydrogenation and polymerisation of the molecule.

Many mixtures of kerosene with acetone, other ketones, alcohol, casing-head gasolene, methyl and ethyl ether, etc., have been proposed and tried. Many of these mixtures work very well, but the average owner wants a fuel that can be purchased at any point on his travels. Such mixtures would usually be found only at the larger towns.

The Southey carburettor[*] or rather "gasifier" seems to work very satisfactorily. In this apparatus the kerosene is sprayed into a chamber, where the spray comes into contact with a small amount of air. A partial combustion takes place, just enough air being admitted to cause sufficient combustion to furnish the heat necessary to gasify the oil. This combustion is started by a spark, but after a minute or two the spark may be cut off. The chamber is so arranged that the large globules of oil from the spray drop to the bottom and are returned to the main tank.

The apparatus works very well in practice. It gives practically no trouble from coking or the formation of evil-smelling products of partial combustion. Kerosene of very much the same composition can be bought all over the world. This certainly seems to be a ready solution of the problem.

Many methods[†] for the manufacture of gasoline from heavy oils have been proposed and quite a number patented. The principle on which most of these work is the distillation of the heavy oil under pressure. The first lots of these gasolines to reach the New York market a year or so ago, were straw-coloured, ill-smelling oils. They had been distilled carelessly and contained considerable proportions of very heavy oils, but during the last few months the quality has been much improved. These gasolines made by high pressure distillation are now being manufactured on a very large scale in this country, but the price is maintained very close to that of the natural petroleum product.

THE THEORETICAL PROBLEMS INVOLVED IN THE CRACKING OF OILS.

BY WALTER F. RITTMAN.

Until recently it has been common to consider the so-called tar and petroleum oils as two separate and distinct materials. The present conceptions of organic chemistry, however, avoid any sharp differentiations, such as those between the methane and benzene series. Instead, all hydrocarbons are considered together, and indicated as differing only in their hydrogen content. The latter classification is more fortunate because in the course of a dozen petroleums from different fields nearly all the various hydrocarbon series are represented. Many petroleums contain considerable percentages of the same constituents that are found in oil or water gas tar. In fact, it is possible to find two petroleums which differ as much in composition as certain petroleums differ from so-called tar.

---

[*] Southey, Eng. Pat. 27,612, Dec. 8, 1911.

[†] For example, Burton, U.S. Pat. 1,049,667, Jan. 7, 1913; Leffer, Eng. Pat. 2328, Jan. 29, 1912.

In dealing with the technical use of petroleum it can be said that we already know something about its end products; it at least appears that we know more about the end products than we do about the application of the most favourable conditions for obtaining maximum yields of the desired end products. It is known that valuable gasoline and illuminating gas can be obtained by cracking petroleum. What we want to know is how to increase the yields of gasoline or illuminating gas from a given amount of oil. It is questionable how much increase can be obtained by the perfection of the well-known methods now in use. Radical increases can result only from the application of radical scientific principles.

In the production of petroleum end products practically all the variables of chemical reactions are involved. While this fact complicates the problem, it makes the field of research more fertile and greatly enlarges its possibilities. We are dealing with chemistry involving both liquids and gases, and with all the physical and chemical principles which apply to both of them. Mechanism of reaction, duration of temperature, contact surface, catalysis, temperature, pressure, and concentration conditions are all vitally important in the cracking of oils. They are all interesting, but in the time allotted me I shall deal with only the last three: temperature, pressure, and concentration.

The information that endothermic reactions work better at high temperatures while exothermic reactions work better at low temperatures is important, but this information does not become fully valuable until we regard as well the chemical equilibria between the various reacting constituents. The subject of chemical equilibrium is studied by practically all undergraduates, but its application to industrial problems, despite its value wherever applied, is still limited. There are very few experimental data dealing with equilibria between hydrocarbon vapours and gases; the principles affecting equilibria in fields which do not involve hydrocarbons are well known, however. There is no reason why these same principles should not be applied directly to hydrocarbons. Doing so leads to theoretical conclusions which suggest experimental research. Application of the principles indicates that the entire problem of cracking oils revolves about the equilibrium or kinetic conception of reaction.

It has been experimentally determined that when hydrogen iodide (HI) is heated, there is a definite percentage of decomposition to H_2 and I_2, dependent upon the temperature of the system. Only at extremes of temperature do the equilibrium conditions carry the reaction completely in one direction. As the temperature is increased the percentage of decomposition increases. Equilibrium conditions prevail when the square of the partial pressure of HI, divided by the product of the partial pressures of H_2 and I_2, equals a constant.

The equilibrium relationships for hydrocarbon reactions have not been determined, but because of the validity of the equilibrium principles and the reversible nature of all chemical reactions investigated, we are reasonably safe in applying the same principles and reasonings to hydrocarbon reactions. The equilibrium considerations are important whatever end it is desired to reach, whether illuminating gas, gasoline, or some other products are the ones being sought. In some cases it will be found desirable to permit the reaction to reach an equilibrium at a relatively high temperature, whereas in other equally important hydrocarbon reactions the equilibrium of this high temperature would be destructive. In either case the equilibrium equation would serve as an indication of the degree of success that might be expected, as well as of the direction the reaction would take. Unfortunately practically none of the numerical values of the equilibrium constants for hydrocarbon reactions have been experimentally determined.

The application of thermodynamic equilibria to hydrocarbons can be illustrated by one or two simple examples. Let us consider the following reactions and their constants (which are approximate):—

	K_{600}	K_{900}
$C_2H_6 \rightleftarrows C_2H_4 + 2H$	0·0027	1·28
$3C_2H_2 \rightleftarrows C_6H_6$	$9 \cdot 10^{33}$	$1{\cdot}2 \times 10^{13}$
$2CH_4 \rightleftarrows C_2H_4 + 2H_2$	0·0000001	0·0004

Any number of others might be taken. Important mathematical expressions which give approximations for the values of these equilibrium constants for hydrocarbons can be found in works on thermodynamics and physical chemistry.* As soon as more of them are known we shall have a better understanding of temperature conditions as related to other conditions in oil cracking processes.

The application of different pressures in the sphere of reaction of the cracking process has been limited. Numerous patents and articles can be found indicating the use of increased pressure in the production of gasoline and illuminating gas. It has long been known that lubricating oils can be recovered more efficiently by distillation under partial vacuum. The distillation of aniline under diminished pressure through the use of steam is common laboratory practice. In such cases, however, the object of the process is not to crack an oil, but to avoid cracking it. So far, the effect of greatly diminished pressure on oil cracking processes is practically uncovered. For a detailed consideration of this aspect of oil cracking see the articles on "Thermal Reactions in Carburetting Water Gas," by Whitaker and Rittman, Jour. Ind. and Eng. Chem., Vol. 6, pp. 383 and 472. To show the effect of varying the pressure when cracking an oil, consider the general reaction, $A \rightleftarrows 2B$, where equilibrium exists when $KA=B^2$. This equilibrium constant is identical with the ones referred to under temperature, and deals with the relative partial pressures at equilibrium under differing conditions of pressure. For numerical illustration assume the value of K to be equal to 1. From this one finds for partial pressures, when $A=100$, $B=10$, or when $A=0{\cdot}01$, $B=0{\cdot}1$. In the first case the partial pressure of A is ten times as great as that of B; in the second case the partial pressure of A is only one-tenth as large as the partial pressure of B. In other words, by simply changing the total pressure on the system and keeping all other conditions constant, the ratio of A to B for the pressures shown has been divided by 100. This change can also be observed by plotting the parabola, $B^2=KA$, where A and B are variables. From this it becomes evident that diminished pressure increases dissociation or decomposition to the gaseous state, whereas increased pressure decreases dissociation. The manufacture of gas under diminished pressure, as reported in the above-mentioned articles, illustrates the former; the present methods of manufacturing gasoline from heavy oils by heating them under increased pressure illustrates the latter.

In dealing with the influence of concentration changes we are applying one of the common laws of physical chemistry. In the dissociation of HI by heat according to equation, $2HI \rightleftarrows H_2 + I_2$, $K = \frac{P_{H_2}P_{I_2}}{P^2_{HI}}$ it is a well-known fact that less of the HI will dissociate in an atmosphere of H_2 or I_2 than in an atmosphere of nitrogen or any other inert gas. This can be observed from a mathematical consideration of equilibrium conditions, purely aside from the chemistry involved. Since the value of K does not change at any given temperature, if the partial pressure of H_2 is increased, the partial pressure of I_2 necessarily decreases unless the partial pressure of HI is increased simultaneously. Assume that the H_2 of the example cited were in excess to the extent that 50%, instead of 10%, of the resultant mixture were hydrogen; what, in this case, would be the partial pressures of HI and I_2, assuming the total pressure to be equal to 1 atmosphere? $0{\cdot}5=$partial pressure H_2, $x=$partial pressure HI, $0{\cdot}5-x=$ partial pressure I_2.

$$K = \frac{P_{H_2}P_{I_2}}{P^2_{HI}} = \qquad 0{\cdot}0156 = \frac{(0{\cdot}5)\ (0{\cdot}5-x)}{x^2}$$

Solving X=0·492 HI. 0·5—X=0·008 I_2, 0·5 H_2. 49·2% HI, 0·8% I_2, 50·0% H_2. Thus, by having a large excess of hydrogen it is possible to eliminate, practically, the uncombined iodine. Or looking at the problem in another way, it is observed that almost none of the HI is dissociated, because of the excess of one of the end products of decomposition. In cracking oil hydrogen and methane are always among the end products.

Drawing an analogy one would expect that cracking petroleum in the presence of an end product, such as hydrogen, would lessen oil decomposition; in ordinary practice some oil decomposition is necessary to produce the hydrogen and other gases required by the equilibrium at that temperature. This decomposition might be avoided by the addition of the necessary hydrogen or other gases from an outside source. In experiments carried out in the laboratory it was found that when oil is cracked in the presence of an excess of hydrogen, not only does none of the hydrogen of the oil split off, but a considerable part of the added hydrogen actually enters into combination. This means that it is not necessary to generate new gaseous end products at the expense of more valuable hydrocarbons.

In conclusion it appears that through the application of physical chemical principles to the cracking of oil, a better control of and greater flexibility in the resultant end products can be expected.

Meeting held at Glasgow on Tuesday, 21st April, 1914.

DR. THOMAS EWAN IN THE CHAIR.

DETERMINATION OF NITROGEN IN GUNCOTTON BY MEANS OF THE NITROMETER.

BY E. G. BECKETT, PH.D.

On account of its simplicity, convenience, and speed, Lunge's method of determining nitrogen in nitrocellulose is now in general use throughout the world. In this method the nitrocellulose is shaken up with mercury and sulphuric acid in a nitrometer and the nitric oxide gas, which is formed by reduction of the nitrates and nitrites, is measured.

During the past ten years, several articles dealing with this subject have appeared, which might arouse scepticism as to the analytical value of the results obtained. Thus Newfield and Marx (J. Amer. Chem. Soc., 1906, **28**, 877), Berl and Smith (Ber. 1907, **40**, 903), Poppenborg and Stephan (Z. ges. Schiess u. Sprengstoffw., 1909, **4**, 350), Berl and Jurrissen (Z. angew. Chem., 1910, **23**, 241), and Marqueyrol and Florentin (Bull. Soc. Chim. France, 1911, **9**, 231) mention instances in which slight modifications of the method have led to the detection of considerable impurities in the nitric oxide evolved. Now, the accuracy of the method depends upon the truth of the assumptions that the gas evolved is pure nitric oxide and that all the nitric acid nitrogen is in the form of nitric oxide. The following research was therefore carried out to ascertain the reliability of the method for guncotton by analysis of the gas evolved and of the residual sulphuric acid.

Besides the ordinary nitrometer method as recommended by Lunge, a modification has also been in use, which, according to some chemists gives results which differ from those given by the original method by as much as 0·25 in the percentage of nitrogen found. Although it was known that these differences exist, it was not known which method gives the truer result.

In the original method, subsequently referred to as Method A, the guncotton is shaken up with sulphuric acid and mercury without the addition of water. In the modified method—Method B—one c.c. of water is added to the 15 c.c. of sulphuric acid and guncotton just before the mixture is shaken.

Details of procedure.—Dry guncotton was sifted and mixed and 0·53 grm. was placed in each of six small weighing bottles. These were placed open in a steam bath for two hours, then closed and kept in a desiccator over calcium chloride.

For each determination, one of the bottles was placed in the balance case for about 20 minutes and weighed accurately and the guncotton shaken into the cup of the nitrometer. The empty weighing bottle was placed in the balance case for 10 minutes and weighed. The guncotton was washed down into the nitrometer with successive quantities of 5, 2½, 2½, and 5 c.c. of 96·5% sulphuric acid (made by dilution from 98·2% pure acid). In the determinations by Method B, one c.c. of water was added at this point, before shaking; in Method A, the shaking was proceeded with without the addition of water. In both methods the nitrometer was shaken for 3 minutes, and then shaken again for one minute after allowing the mercury globules to settle. The pressure of the gas was reduced to slightly below atmospheric pressure and the nitrometer allowed to stand for ¼ of an hour in this

Results:—

Method A.

condition in order to give the nitric oxide every chance of escaping from the sulphuric acid. The gas was then transferred to a second nitrometer—the measuring nitrometer—where it was allowed to remain for a quarter of an hour before being measured. This measuring nitrometer was surrounded by a water jacket, and had a water pressure gauge for determining accurately when the gas inside the nitrometer was at atmospheric pressure. The sulphuric acid residue was at the same time removed from the first nitrometer—the shaking nitrometer—transferred to a Kjeldahl flask, and the nitrogen determined by Kjeldahl's method as described below.

Analysis of the nitric oxide.—After the nitric oxide had been measured, it was shaken with 20—30 c.c. of concentrated ferrous sulphate solution. The gas residue was then transferred to a small gas burette where it was successively treated with ferrous sulphate, potassium hydroxide, ammoniacal cuprous chloride, in order to determine the carbon dioxide, carbon monoxide and nitrogen. After it had been found that very little carbon dioxide—at the most 0·03 c.c.—was in the residue, the treatment with potassium hydroxide was discontinued and the carbon monoxide and carbon dioxide determined together by absorption in ammoniacal cuprous chloride.

Estimation of nitrogen in the sulphuric acid residues.—The sulphuric acid from the nitrometer determination was placed in a stoppered separating funnel, treated with 5 c.c. of a 1% solution of potassium permanganate in sulphuric acid to oxidise all the nitric oxide to nitric acid and then 2 grms. of salicylic acid was added. The stopper was then inserted and the acids mixed. After standing for half an hour, the mixture was allowed to flow into a round-bottomed Jena flask and the funnel washed with 20 c.c. of sulphuric acid. The mixture was then slightly warmed to nitrate the salicylic acid as far as possible, cooled and 2 grms. of zinc dust added gradually. The mixture was allowed to stand for half an hour, heated over a small flame till all the zinc was dissolved and then boiled vigorously for 15 minutes; 15 grms. of sodium sulphate was then added and the solution boiled until colourless. The ammonia was determined in the usual way. The method was tested with a synthetic solution of concentrated nitric acid in concentrated sulphuric acid and found to yield the following results:—0·947, 0·947, 0·948% of nitrogen instead of 0·956%.

The difference, 0·065%, between the percentage of nitrogen by these two methods was smaller than was expected, for chemists had in former years obtained results differing by as much as 0·25%. The following attempts were therefore made to account for the discrepancy.

Effect of stronger sulphuric acid.—It was thought possible that greater differences might be obtained if sulphuric acid of a higher concentration were used. The following experiments were therefore carried out by Method B with the same guncotton, 98·2% acid being used:—

Weight of Guncotton grm.	Gas c.c.	Temp. ° C.	Press. m.m.	% N. uncorrected.
0·5131	115·5	20·35	762·15	13·14
0·5161	114·95	19·2	765·9	13·2
			Mean	13·13

It will thus be seen that the employment of higher concentrations of acid produces practically no increase in the quantity of gas evolved, due to the addition of water.

Effect of using warm mercury.—An experiment was carried out by Method B with the mercury in the nitrometer heated to 25° or 30° C., but the result 13·10% N did not differ from the others obtained by the same method. The heat evolved on the addition of 1 c.c. of water to 15 c.c. of concentrated sulphuric acid is evidently so great that it is not appreciably increased by warming the mercury.

Equalisation of temperatures inside and outside nitrometer.—It was also thought that the equalisation of temperature between the gas inside the ordinary non-jacketed nitrometer and the atmosphere of the room may not take place within the time recommended for the purpose in the method. The greater heat caused by the addition of the one c.c. of water in Method B might then account for the differences between the above results and those obtained by other chemists.

A dummy nitrometer with a thermometer inside was heated in a steam bath, taken out and allowed to cool in the room. The temperatures inside and outside the nitrometer were observed every 5 minutes.

Time—Min.	Temp. inside.	Temp. outside.	Difference.
0	36·0	15·7	20·3
5	23·0	15·8	7·2
10	18·8	15·5	3·3
15	17·4	16·0	1·4
20	17·0	16·0	1·0
25	16·8	15·6	1·2
30	16·6	15·6	1·0

These results show that after twenty minutes, it is unlikely that a difference of temperature greater than 1° C. would exist between the inside and the outside of the nitrometer, and a difference of 1° C. would account for a difference in the results of only 0·03, making altogether a difference of 0·09 to 0·12 in the percentage of nitrogen found by the two methods.

Thus, all attempts to obtain or account for greater differences than those described above failed, and the only possible explanation left was that the sulphuric acid used in this research was different in purity from that used previously.

Cause of difference in the results by the two methods.—It will be noticed that the difference of 0·065% between the two methods is unaccounted for by the analysis of the gas and of the residual sulphuric acid. The amount of nitrogen left in the sulphuric acid showed no difference whatsoever and it surely would have done so, had the difference of 0·065% been caused by a greater evolution of nitric oxide. It may therefore be assumed that the difference was entirely caused by impurities in the gas. The results obtained, however, accounted for a difference of only 0·2 c.c., which was observed in the quantity of CO, the nitrogen being the same in both methods, whereas, the difference of 0·065% demands a difference of about 0·6 c.c.

It must be remembered that in analysing the nitric oxide, it had been shaken up with 20—30 c.c. of concentrated ferrous sulphate solution, this quantity being necessary for the absorption of over 100 c.c. of nitric oxide. Such a quantity of liquid is liable to absorb not only all the carbon dioxide and sulphur dioxide contained in the nitric oxide, but also some of the carbon monoxide which is soluble in water to the extent of 2·3% at 20° C. It seemed, therefore, desirable to re-determine the carbon monoxide, carbon dioxide and sulphur dioxide by a method in which the use of large volumes of the absorbents were avoided.

As the ferrous sulphate solution had been made with ordinary distilled water, which had been for some time in contact with the air and, as the solubility of nitrogen is only about 1·5% in water and 0·6% in salt solution, it is probable that the figure obtained for the nitrogen content was not far from the truth. No attempt was therefore made to repeat the determination of the nitrogen.

Improved method of determining the impurities in the nitric oxide.—In the following experiments, the nitric oxide, after it had been measured was passed back into the first nitrometer, where it was allowed to remain in contact with 1 c.c. potassium hydroxide solution for about 10—15 minutes, after which it was passed into the measuring nitrometer and measured. The reduction in volume gave the quantity of SO_2+CO_2 in the gas. If the potassium hydroxide solution contained dissolved air, that air would combine with the NO to form NO_2 which would then be absorbed by the potassium hydroxide. The amount of this absorption was determined by treating the nitric oxide which had been freed from CO_2 and SO_2 with a fresh c.c. of the same potassium hydroxide solution and allowing it to remain in contact for 10 minutes as in the actual determination of CO_2 and SO_2. This absorption of NO caused by dissolved air was 0·12 c.c. It was subtracted from the contraction in the actual determination of the CO_2+SO_2.

After the nitric oxide had been freed from CO_2 and SO_2, oxygen was added and the nitrogen peroxide formed was absorbed by 1 c.c. of potassium hydroxide. Care was taken not to add an excess of oxygen. The gas residue of 5—10 c.c. was then passed into a gas burette, where it was treated with a few c.c. of ferrous sulphate solution until free from nitric oxide, measured, treated with ammoniacal cuprous chloride then with dilute hydrochloric acid and measured again. The contraction was taken as CO.

* Mercury warmed to 25°—30° C.

The total quantity of non-nitrogenous gases, that is of CO_2+SO_2+CO found in the nitric oxide in Method A was 0·73 c.c., whereas in Method B it was 1·25 c.c. The difference, 0·52 c.c., is equivalent to 0·06% in the result for the nitrogen in the guncotton. Thus, the slightly higher values found by Method B were accounted for by an increase in the quantity of CO_2, SO_2 and CO present in the nitric oxide. The increased evolution of these bye-products was entirely due to the heat produced by the mixing of the sulphuric acid with water, for when the acid and water was mixed and cooled before the experiment, no difference could be observed between the results by the two methods, as the following comparative experiments show :—

Method A.

Weight of guncotton	Vol. of Gas	Temp.	Press.	N %.
gm.	c.c.	°C.	mm..	
0·5146	113·85	17·3	760·6	13·03

Method B.

(15 *c.c.* 96·5% *acid mixed with* 1 *c.c. water and cooled before experiment*).

Weight of guncotton	Vol. of Gas.	Temp.	Press.	N %.
grm.	c.c.	° C.	mm.	13·035
0·5189	114·85	17·1	760·22	

The correctness of the results by Method A.—The above experiments show that the 115 c.c. gas evolved from 0·51 grm. guncotton contained 0·73 c.c. non-nitrogenous gas, 0·6 c.c. of nitrogen and that the sulphuric acid residue contained nitrogen equivalent to 0·75 c.c. of nitric oxide.

Thus, the error involved by measuring 0·73 c.c. of $CO_2+CO+SO_2$ was neutralised by the nitrogen equivalent to 0·75 c.c. NO left in the sulphuric acid.

The 0·6 c.c. nitrogen in the nitric oxide was partly derived from the sulphuric acid used, which was found to contain 2·5% by volume of nitrogen gas besides about 0·5% by volume of oxygen gas. Thus, the 15 c.c. of sulphuric acid used for one determination contained 0·4 c.c. of nitrogen. The sulphuric acid after a determination was found to contain only 0·05 c.c. of nitrogen gas, showing that 0·35 c.c. of the 0·6 c.c. nitrogen in the nitric oxide had been derived from the sulphuric acid. The rest of the nitrogen, 0·25 c.c., was probably produced by reduction from the nitric oxide as shown by Marqueyrol (Bull. Soc. Chim. France, 1911, 9, 231). Now, 0·25 c.c. nitrogen or nitrous oxide is equivalent to 0·5 c.c. nitric oxide, and therefore, in this case also, the two errors practically neutralised one another.

Thus, the errors in the determination of nitrogen by Method A balanced one another and the results may be taken as correct.

Solubility of nitrogen in sulphuric acid.—No figures having been found in the literature for the solubility of nitrogen in sulphuric acid, it was thought advisable to ascertain whether the 15 c.c. of sulphuric acid could contain more than 0·4 c.c. of nitrogen to be subsequently evolved during the decomposition of the guncotton. A quantity of the 96·5% sulphuric acid set apart for the determinations was therefore placed in the bottom of a glass-stoppered bottle and shaken for about 6 to 7 hours. After it had been allowed to stand for about 5 days, the 96·5% sulphuric acid, which it could now be said had been brought into equilibrium with the air, was found to contain only 0·22 c.c. of nitrogen per 15 c.c. acid, that is, little more than half the quantity it contained before being shaken.

The original 98·2% acid from which the 96·5% acid was made, was found to contain 0·42 c.c. nitrogen per 15 c.c. acid—a quantity slightly greater than that found in the unshaken 96·5% acid. Thus, it would appear that the 96·5% sulphuric acid has a smaller solubility for nitrogen than the stronger acid, and, hence, was supersaturated with this gas, which was partly given off again when the acid was agitated. These results prove, however, that there is no probability of the 96·5% sulphuric acid containing appreciably more nitrogen gas than it was found to contain above.

The nitrogen in the sulphuric acid residues.—An attempt was also made to ascertain in what form the nitrogen is left behind in the residual sulphuric acid. Only a trace of ammonia could be found and the dissolved gases contained besides carbon monoxide and carbon dioxide 0·25 c.c. of nitric oxide and 0·05 c.c. of nitrogen.

On distilling the sulphuric acid residue left after the determination of dissolved gases with ferrous sulphate solution and sodium chloride, 0·2 c.c. of nitric oxide was further obtained, which may be said to have been derived from undecomposed organic nitrate or nitrite.

The cotton used for the manufacture of guncotton was found by Kjeldahl's method to contain 0·012 and 0·014% of nitrogen. This nitrogen in 0·51 grm. of guncotton is equivalent to 0·05 c.c. nitric oxide and is probably present in the cotton as albuminoid ammonia. Thus, of th nitrogen present in the residual sulphuric acid, which b Kjeldahl's method was found to be equivalent to 0·75 c.c nitric oxide, nitrogen equal to 0·25 c.c. nitric oxide is stil unaccounted for. The determination of the dissolve nitric oxide was conducted with all care, but som authorities declare that it is impossible to remove the las traces of the gas from watery solutions by boiling, an hence the values obtained for the dissolved nitric oxid gas and undecomposed nitrate may be somewhat low Thus, according to Lunge, the volume of the dissolve nitric oxide in 15 c.c. of sulphuric acid should be 0·33 c.c which is rather higher than the value found above.

Summary.—As far as could be ascertained from an exam ination of the gas evolved, of the residual sulphuric aci and of the sulphuric acid used, the ordinary nitromet method (Method A), of determining nitrogen in guncott gives correct results.

The 111—115 c.c. of nitric oxide evolved by this meth from 0·51 grm of guncotton contains about 0·4 c.c.

carbon dioxide + sulphur dioxide, 0·3 c.c. carbon monoxide and 0·6 c.c. of nitrogen. The residual sulphuric acid was found to contain nitrogen equivalent to 0·75 c.c. nitric oxide.

The 15 c.c. of 96·5% sulphuric acid used contained about 0·4 c.c. of nitrogen gas, of which 0·35 c.c. was evolved during the determination of nitrogen in guncotton.

The errors produced by these impurities balance one another, so that if the gas evolved is supposed to be pure nitric oxide and to contain all and only the nitrogen in the guncotton, correct results are obtained.

The method in which 1 c.c. of water is added gives slightly higher results than the above method, the increase in the volume of the gas evolved being caused by the presence of a larger quantity of carbon dioxide + carbon monoxide + sulphur dioxide in the nitric oxide. The greater quantity of these gases is caused solely by the heat evolved on adding one c.c. of water to 15 c.c. of sulphuric acid and is not due to the use of more dilute acid.

I wish to express my indebtedness to Colonel Sir Frederic L. Nathan and Messrs. Nobel's Explosives Coy. for permission to publish this paper.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, German.

I.—GENERAL PLANT; MACHINERY.

Patents.

Drying grain and other fine materials; Apparatus for ——. Soc. de Constructions Mécaniques d'Alais, France. Eng. Pat. 9489, April 22, 1913. Under Int. Conv., June 21, 1912.

The grain is passed down a tower provided with a number of superposed horizontal partitions each formed of concentric rings, the spaces between the rings of one partition being beneath the rings of the next. The material is transferred from partition to partition by stirrers which are supported by arms projecting from and rotated by a central shaft, and have blades corresponding with the rings. Drying is effected by a current of hot air or gas passed upwards through the tower.—W. H. C.

Dryer; Continuous automatic ——. C. A. Wendell, Joliet, Ill. U.S. Pat. 1,088,754, March 3, 1914.

A centrifugal dryer which can be operated continuously comprises a circular chamber rotating horizontally and carrying a number of pockets at the periphery for the material to be dried. The material is fed to these pockets by a spout which rotates at a slightly different speed from that of the separator, so that the pockets are filled in turn, the time occupied in filling all of them being, say, one minute. The pockets are provided with perforated plates through which the liquid discharged by centrifugal action escapes, and have hinged bottom plates which are periodically opened by a cam carried by the charging spout so as to discharge the dried material just before the fresh charge is introduced.—H. H.

Drying by compressed air; Apparatus for ——. W. E. Hall, Assignor to C. A. Tatum, New York. U.S. Pat. 1,091,215, March 24, 1914.

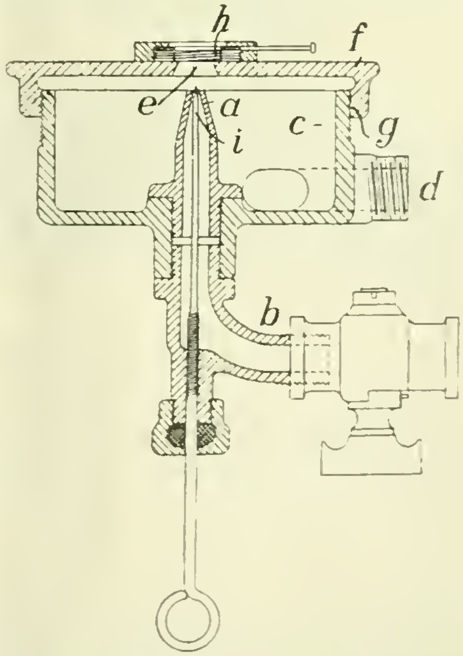
Air is compressed and passed through water-cooled pipes or through a chamber containing baffle-plates whereby the moisture is condensed. The dried air then flows through a reducing valve into a heating chamber, and thence to a chamber where it is used as a drying medium. —H. H.

Drying loose materials. A. Hofmann. Fr. Pat. 465,966, Nov. 20, 1913. Under Int. Conv., Nov. 12, 1912.

The material is dried upon a series of superposed travelling bands within a chamber. It is fed on to one end of the uppermost band and drops from the other end on to the band next below, travelling in the opposite direction, and so on to the bottom where it is discharged. The speed of the bands is decreased from the top downwards to compensate for the shrinkage of the material due to drying. Furnace gases are passed through a series of longitudinal flues below the chamber and air is blown by a fan through a number of transverse flues which pass through the longitudinal flues. The heated air rises up through the chamber and is withdrawn from the top by a fan.—W. H. C.

Spraying or atomising liquids by air or gases; Appliances for ——. E. Samuelson, Banbury, and J. Backhouse, Bootle. Eng. Pat. 9823, April 26, 1913.

The liquid enters the box, *c*, from the pipe, *b*, through the nozzle, *a*, provided with the needle valve, *i*, and the air or gas enters the box tangentially through the pipe, *d*. The cover, *f*, of the box is screwed on as indicated



at *g*, so that the distance between the nozzle, *a*, and the orifice, *c*, through which the mixture of atomised liquid and air escapes can be adjusted. The orifice, *c*, is provided with an iris diaphragm, *h*, by which the size of the aperture can be varied.—W. H. C.

Spraying apparatus for the treating of gases and vapours with liquids. C. H. Fowler and E. A. Medley, Liverpool. Eng. Pat. 10,963, May 9, 1913.

In the apparatus described in Eng. Pat. 23,864 of 1911 (this J., 1912, 1167) in which the washing liquid is sprayed from a number of horizontal discs mounted on a rapidly rotating vertical shaft, a series of vanes or a single cylinder provided with a lip at its lower edge, or a combination of both, is arranged around the shaft below the discs so as to dip into the liquid in the tray beneath. When the shaft is rotating, the vanes or cylinder cause the liquid to rise up until it reaches the level of a series of openings, pierced in the cylindrical support of the discs, through which it escapes and is again sprayed by the discs.—W. H. C.

Air, gas or vapour, and liquids ; Means and apparatus for the treatment of ——. L. Chew, London. Eng. Pat. 24,601, Oct. 29, 1913.

Wire netting is wound tightly round a perforated vertical cylinder which is fixed within a casing: at the top the cylinder makes a gas tight joint with the casing. Washing liquor is supplied at the top, flows downward through the annular coil of netting, and collects in the lower part of the casing, sealing the lower open end of the perforated cylinder. The air or gas to be purified, is delivered horizontally into the casing, passes through the meshes of the netting, thus coming into intimate contact with the washing liquor, and is withdrawn from the interior of the perforated cylinder.—W. H. C.

Spraying pulverulent or other materials with liquids ; Plant or installation and apparatus for ——. C. E. Gardner, Gloucester. Eng. Pat. 10,548, May 5, 1913.

The material to be sprayed by means of a compressed air spraying device on to the pulverulent or other material is contained in two vessels so connected that they may serve alternately to supply the atomiser; or a single vessel may be used in which a constant head is maintained by means of a force pump or a ball valve.—W. H. C.

Furnace ; Regenerative ——. H. Walsh and A. Priestley, Halifax. Eng. Pat. 10,950, May 9, 1913.

The waste gases pass backwards and forwards through horizontal tubes arranged on each side of the producer, and the secondary air for the combustion of the producer gas is preheated by circulating around the tubes in an ascending zigzag direction. The tubes have a rectangular external section and a circular bore, and the secondary air inlet tubes are formed with an open or slotted side. A baffle-plate is fixed between each tier of tubes to lengthen the path traversed by the secondary air.—T. St.

Gas furnaces of the Siemens type ; Reversible regenerative ——. A. Reynolds, London. Eng. Pat. 14,541, June 24, 1913.

To obviate danger of explosion in the flues and stack and to increase the efficiency of the regenerators, separate flues and draught-producing devices are provided for each reversing valve system.—W. H. C.

Filters. H. Sefton-Jones, London. From K. Kiefer, Cincinnati, Ohio, U.S.A., Eng. Pat. 14,136, June 18, 1913.

The filter consists of a wide shallow tray containing a sheet of filtering paper with ridges embossed thereon, the ridges on the bottom running diagonally towards a spout at one corner of the tray, and the ridges on the sides running vertically. The ridges are terminated at a short distance from the folded edges so as to leave an unembossed space around the bottom close to the sides. Some of the uprigh ridges adjacent to the corners are embossed on opposit sides of the paper so that the overlapping portions of pape at the corners are separated by the ridges.—H. H.

Filters. J. H. Carruthers and Co., Ltd., and J. Gourlay C. M. Jackson and G. K. Johnstone, Glasgow. Eng. Pat 14,396, June 21, 1913.

A number of filter elements is arranged within a casing Each element is formed of filtering material stretched o a cylindrical frame constructed of perforated metal rod having a wire threaded helically through the perforation The filter is intended more particularly for the remova of oil or grease from feed water for steam generators. —W. H. C.

Slime cakes ; Process of dislodging ——. *Filtering lea* G. W. Shepherd, New York, Assignor to The Butter Patent Vacuum Filter Co., Me. U.S. Pats. 1,096,13 and 1,096,133, May 12, 1914.

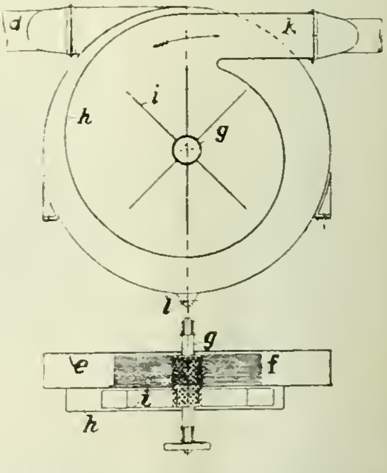
Pipes are provided on each side of the upper edge of th filter-leaf for the purpose of supplying water under pressur between the surface of the filtering medium and the bac of the cake in order to dislodge the latter.—W. H. C.

Separating specifically heavier admixtures from gases an vapours ; Apparatus for ——. E. Kluge, Leipzi Germany. Eng. Pat. 22,646, Oct. 7, 1913. Und Int. Conv., Oct. 8, 1912.

Oil, etc., is separated from steam or other vapours or a by means of baffles built up of alternate non-perforate corrugated plates and flat perforated plates so arrang that the gases flowing between any two adjacent corrugate plates have to pass backwards and forwards through t perforated plate separating them.—H. H.

Gases and liquids ; Apparatus for separating suspend impurities from ——. C. Pfaul, Nachf. von F. Bod Ger. Pat. 272,288, Dec. 10, 1912.

A number of discs, *f*, are mounted close together on hollow, perforated shaft, *g*, within a casing, *e*, adjacent which is the casing, *h*, of a centrifugal fan, *i*. The gas be purified enters at *d*, and the purified gas is drawn throu the perforated hollow shaft and forced out through The impurities are prevented from reaching the holl shaft by the discs, *f*, and are continuously projected o wards by centrifugal force: they accumulate in casing and are removed by the screw, *l*.—A. S.



Centrifugal-machines. J. A. Nordström. Stockho Sweden. Eng. Pat. 22,989, Oct. 11, 1913.

The vertical spindle of the centrifugal machine is journal in both ends of a socket free to oscillate laterally, an engaged between the ends by the screw drive. The socket is retained in position by longitudinal springs which press against its lower end.—W. H. C.

Pulverisers. E. C. R. Marks, London. From Blake Crusher and Pulveriser Co., Pittsburg, Pa., U.S.A. Eng. Pat. 27,162, Nov. 25, 1913.

The material is fed into the crusher from a hopper provided with a rotating screw which is tapered towards its receiving end; the radial length of the blades of the screw is reduced in the direction of the taper.—W. H. C.

Compressed gases; Preventing the freezing of vapour during the discharge of —— from storage vessels. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Procédés G. Claude, Paris. Eng. Pat. 746, Jan. 10, 1914. Under Int. Conv., Jan. 14, 1913.

The high-pressure gas chamber is thermally insulated from the expansion chamber by non-conducting material. —W. H. C.

Separating gases from liquids. F. Strohbach, Charlottenburg, Germany, Assignor to General Electric Co. U.S. Pat. 1,095,478, May 5, 1914.

The liquid is introduced from below into a conical chamber having an opening at the apex, where it overflows in a thin film, passing over the outer surface of the cone into a surrounding tank. The occluded gases become separated as the liquid descends, and escape into the upper portion of the tank.—H. H.

Solution, purification and crystallisation of substances which are only slightly soluble in water; Process of —— and apparatus therefor. L. M. Rousseau Fr. Pat. 465,540, Feb. 8, 1913.

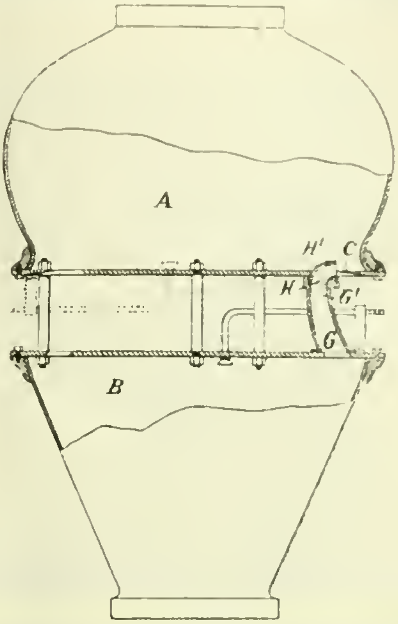
The substances are dissolved at as high a temperature as practicable in an autoclave provided with an agitator. The solutions are purified by filtration in a second autoclave and received in a third in which crystallisation is allowed to take place either rapidly with agitation or slowly without agitation according to the product required.—W. H. C.

Extractor; Cylindrical, vertical ——. Harburger Eisen und Bronzewerke A.-G. Fr. Pat. 465,640, Dec. 4, 1913.

The vertical shaft carrying the agitator blades passes through a stuffing-box in the centre of the bottom of the cylinder. The stuffing-box is sealed by a liquid which is not miscible with the solvent used in the extractor. —W. H. C.

Gaseous mixtures; Process and apparatus for the separation of ——. E. N. Mazza. Ger. Pat. 272,853, Dec. 10, 1912.

The separation is effected by converting the potential energy of the gaseous mixture into kinetic energy by passage through a curved tube of diminishing cross-section from inlet to outlet, whereby the lighter and heavier constituents accumulate respectively nearer to, and more remote from, the centre of curvature of the tube. The apparatus (see Fig.) consists essentially of a chamber, B, to which the gaseous mixture is supplied, another chamber, A, to receive the separated heavier constituent, and between these one or more separating elements, each consisting of two portions, viz., G,G′ in which transformation of the potential energy of the mixture into kinetic energy first takes place, and H,H′, which is the separator proper: the separated heavier constituent is diverted into A by the partition, C. The tubes, G,G′, and H,H′, consist of cylindrical surfaces joined by flat side walls, and are curved in such a manner that together they have substantially the form of an archimedean spiral. The radius of curvature of the tubes diminishes continuously from the inlet to the outlet; the convolution of the portion H,H′, may be twice the length of the mean radius of curvature of this portion, and the convolution of G,G′, is several times as long as that of H,H′.—A. S.



Evaporation; Continuous ——. M. Prager, Berlin. U.S. Pat. 1,096,193, May 12, 1914.

See Fr. Pat. 449,572 of 1912; this J., 1913, 525.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal solvents. L. Vignon. Comptes rend., 1914, **158**, 1421—1424.

The action of alcohol, ether, benzene, toluene, aniline, nitrobenzene and quinoline was investigated. In the case of a bituminous gas coal from the Loire district, aniline dissolved 23·4% and quinoline 47·3% at the boiling-point. With bituminous coal a smaller proportion is soluble. The dissolved substances are precipitable by acid. The soluble part is richer in hydrogen and lower in ash than the insoluble portion. The coke from the former is vesicular and glassy, that from the latter is powdery. —J. L. F.

Electrical ignition of gaseous mixtures. W. M. Thornton. Roy. Soc. Proc., 1914, A, **90**, 272—297. (See also this J., 1913, 935 and 1149).

The results of a comprehensive investigation of the relation between the nature of the combustible gas, the composition of the mixture, the voltage, and the magnitude of the least igniting current (continuous and alternating) are given in numerous diagrams. The current required for ignition diminished very rapidly as the voltage was raised, the curves obtained for continuous current being similar to those which are characteristic of steady arcs. With alternating current the variation with frequency is shown in Fig. 1. In the paraffin series the relation of the least igniting current to the composition of the gas was different for continuous and alternating currents. Continuous currents gave curves (see Fig. 2) the middle portions of which were straight lines all passing through zero or nearly so, showing that the igniting current was proportional to the number of molecules of combustible gas in unit volume of mixture. The same igniting current was required for each most inflammable

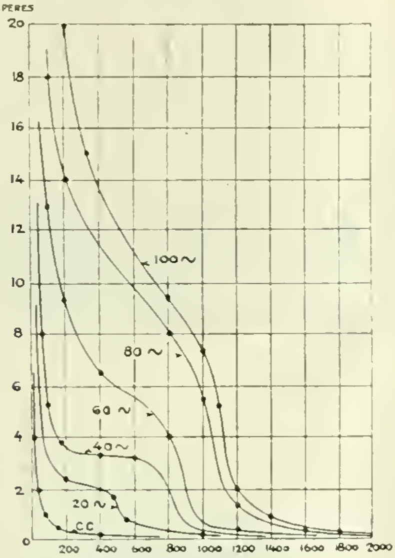


Fig. 1.
Influence of frequency in igniting current in a 9·5 per cent. mixture of methane and air. Iron poles, alternating current.

mixture, and such mixtures contained as a rule a slight excess of air. The slope of the straight portion of the curve was greatly diminished by an increase in the voltage. Alternating currents gave curves which had no straight portion and were almost symmetrical between the limits of inflammability. The minima were at different current values, but the minimum current multiplied by the percentage of inflammable gas in the corresponding mixture was the same for all members of the series. The igniting current was always greater for alternating than for continuous current with the same voltage. The compositions at the minima of the alternating current curves corresponded with combustion to equal proportions of carbon monoxide and dioxide. The alcohols gave curves similar to those for the paraffins. Benzene gave with both currents almost symmetrical curves with no straight portion and the most sensitive mixture corresponded with combustion to carbon monoxide. Carbon bisulphide gave curves with a straight portion for both currents and the minimum corresponded with complete combustion to carbon dioxide. With hydrogen and carbon monoxide both curves (alternating and continuous) had a straight portion, but in the continuous current curve for hydrogen the straight portion was horizontal and in the alternating current curve it was slightly inclined. For carbon

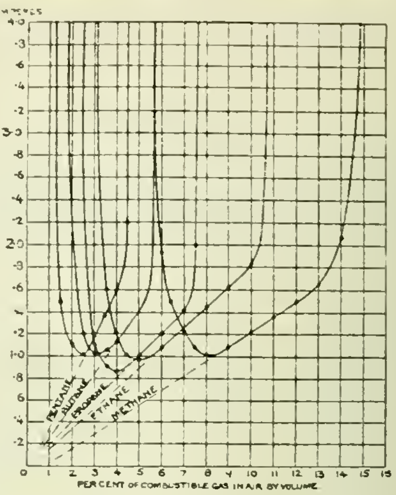

Fig. 2.
Least igniting currents for the paraffin gases in air. Continuous current. Iron poles. 100 volts.

monoxide these conditions were reversed. External ionisation (from X-rays or ultra-violet radiation), which did not itself cause ignition, had no influence on the minimum igniting current.—W. H. P.

Gas; Uses of——. W. A. Bone. Report of Brit. Assoc., 1913, 440—444.

After referring to the industrial applications of coal gas, water-gas, producer gas, and blast-furnace and coke-oven gases (compare this J., 1907, 674; 1908, 1008; 1910, 395; 1911, 1455; 1912, 114; 1913, 1013, 1057), it is stated that at the Skinningrove Ironworks, since October, 1911, blast-furnace gas enriched with coke-oven gas up to 130 B.Th.U. per cb. ft. has been regularly supplied to boilers, power house, and soaking pits, the whole of the steel output of a 275-ton Talbot furnace being converted into finished steel sections without the use of any outside fuel. By supplying the Talbot furnace with an enriched gas of 180 B.Th.U., a saving of 2½—3 cwt of coal per ton of steel was effected.—A. S.

Naphthenic acids from different petroleum distillates. E. Pyhälä. Chem. Rev. Fett Ind., 1914, 21, 128—130.

Commercial naphthenic acids prepared from a series o distillates from Baku petroleum oil had the followin characters :—

Naphthenic acid from	Neutralisation value.	Sp. gr. at 15°/15° C.	Viscosity (Engler) at 30° C.	Iodine value (Hübl-Waller)	Corresponding petroleum fraction.	
					Sp. gr. at 15°/15° C.	Viscosity at 30° C.
Kerosine	310	0·9860	—	—	0·8255	1·05
Do.	255	0·9650	4·23	0·9	0·8250	1·08
Pyronaphtha	186·5	0·9521	8·35	—	0·8640	1·45
Light solar oil	170·0	0·9513	15·00	2·42	0·8818	2·10
Vaseline oil fraction	152·0	0·9471	—	—	0·8894	3·20
Heavy solar oil	136·0	0·9418	18·90	2·50	0·8924	3·40
Spindle oil	108·0	0·9358	34·76	6·17	0·9020	7·12
Machine oil	87·5	0·9350	47·71	7·18	0·9100	16·12
Cylinder oil	32·6	0·9294	97·92	11·36	0·9210	(40° C.) 31·30

The relatively low neutralisation values accompanyir fairly high iodine values were probably due to tl naphthenic acids being partly in combination wit unsaturated hydrocarbons (probably terpenes). Th would account for the difficulty of isolating pu

naphthenic acids of high molecular weight. A fairly pure naphthenic acid was isolated from the ordinary waste lyes from the refining of machine oils. This had sp. gr. 0·9470 at 19·8° 15° C.; neutralisation value, 169·7; and iodine value, 2·54. On fractional distillation it yielded about 13% of eikosinaphthenic acid, $C_{20}H_{38}O_2$, and 63% of eikosipentanaphthenic acid, $C_{25}H_{48}O_2$.
—C. A. M.

Mineral oil industry of the Caucasus. Board of Trade J., May 28, 1914. [T.R.]

It will be seen from the following table that, owing to the large falling-off in the output of the Baku, Chelekon, and Maikop oilfields, the production of petroleum in the Causasus in 1913 showed a decrease of 211,387 tons as compared with the previous year:—

Oilfield.	Production.	
	1912.	1913.
	Tons.	Tons.
Baku	6,758,054	6,290,323
Island of Cheleken	209,677	129,032
Surachani	500,000	629,032
Grozni	1,048,389	1,129,032
Maikop	145,161	96,774
Other sources	662,880	838,581
Total	9,324,161	9,112,771

The decline in Russian production is attributed principally to the strikes at, and the exhaustion of, the wells in the Baku area. The number of feet drilled in 1913 was 219,625 against 192,423 in 1912. Although progress in prospecting on new oil-bearing lands was made during the year, it is too soon yet to arrive at any conclusions as to the possibilities of the two areas which have come under exploitation. Petroleum prospecting work in Gouria was not very successful, but three derricks are being erected preparatory to commencing boring operations. A black thick oil, not heavy, has been met with in the district, and it is possible that now drilling operations are to be taken in hand prospects in this locality may be more promising than they were in 1913. The exploratory work done during the year on the Taman peninsula was not attended with results of a very promising character.

According to a review of the petroleum industry in 1913, published by the Baku Petroleum Association, the following changes took place in the production of crude oil during the year as compared with the figures of 1912. In order to show the leading position Russia held in the oil industry of the world in 1901 the approximate figures of the production of that year are also given.

Country.	1901.	1912.	1913.
	Tons.	Tons.	Tons.
United States	8,951,000	29,161,000	31,984,000
Russia	10,984,000	9,324,000	9,113,000
Mexico	—	2,450,000	2,968,000
Roumania	226,000	1,774,000	1,839,000
Dutch East Indies	613,000	1,452,000	1,645,000
Austria-Hungary	451,000	1,177,000	1,016,000
Other countries	484,000	1,709,000	1,919,000
Total	21,709,000	47 047,000	50,484,000

Patents.

Furnaces and fuel feeding devices therefor. C. J. Greenstreet, St. Louis, Mo., U.S.A. Eng. Pat. 1515, Jan. 18, 1913. Under Int. Conv., Sept. 26, 1912.

Powdered coal is fed from a hopper, through adjustable oors at the bottom, to a feed-box, whence it is transorted by adjustable conveying gear to the blower placed just below, within a casing. The air enters the blower from the casing which is provided with an adjustable damper.—W. H. C.

Combustion of gaseous or vapourous combustibles; Apparatus for the catalytic combustion of ——. L. Schmidt, Düsseldorf, and F. Krieger, Berlin, Germany. Eng. Pat. 9678, April 24, 1913. Under Int. Conv., April 24, 1912.

A burner of the Bunsen type is fitted with a closed hollow extension made of a highly porous refractory material, such as closely woven asbestos, impregnated with a catalytic material such as finely divided platinum. The gases burn on the outer surface of the porous body, no combustion taking place within it.—H. H.

Fuel; Compositions for aiding the combustion of ——. A. Morin, L. Hamon and E. Hess, Montreal, Canada. Eng. Pat. 27,648, Dec. 1, 1913.

The fuel is sprayed with a solution of sodium chlorate or perchlorate and permanganate.—W. H. C.

Coal; Preparation of a solution for economising ——. H. Lewison. Fr. Pat. 465,995, Dec. 8, 1913. Under Int. Conv., Sept. 4, 1913.

An aqueous solution of a mixture of powdered potassium nitrate, 60, calcined sodium carbonate, 32, and potassium permanganate, 8%, is poured over coal for the purpose of securing a more complete combustion thereof.—H. H.

Fuel briquettes. T. H. Peters, sen., Chiswick, T. H. Peters, jun., Brentford, Middlesex, G. L. and C. P. Tuxford, Richmond, Surrey. Eng. Pat. 4757, Feb. 24, 1914.

Powdered fuel is agglomerated into briquettes by means of a mixture of 1 cwt. of Portland cement, 5 oz. of potassium permanganate, and 5 lb. of ochre to each ton of coal, coke, or peat.—H. H.

Coal and lignite; Briquetting —— by means of a mixture of pitch and oils resulting from the distillation of tar oils. V. Moreau. Fr. Pat. 465,530, Dec. 1, 1913. Under Int. Conv., Sept. 23, 1913.

Coal dust, etc. is mixed with powdered pitch, and sufficient tar oil is added to dissolve the pitch, the resulting paste being moulded into briquettes.—H. H.

Briquettes from waste wood: Manufacture of ——. E. Eckstein and C. Wislicki. Fr. Pat. 466,363, Dec. 18, 1913.

Waste wood or sawdust (80 kilos.) is impregnated with rosin (25 kilos.) in a heated vacuum chamber, and the mass is compressed into moulds which have been sprinkled with sawdust to prevent adhesion of the blocks.—H. H.

Agglomerating coal and other powdered materials; Process for ——. H. Steven, Fr. Pat. 466,420, Dec. 20, 1913. Under Int .Conv., Jan. 20, 1913.

A mixture of a powdered material (*e.g.* coal dust) and an agglomerant is subjected in moulds to a series of pressing operations of increasing intensity, air and gases being eliminated in the first, liquids in the second, and consolidation taking place in the third. Any cracks produced by the heavy compression are closed by a final light compression. The apparatus used comprises a circular plate containing the moulds and a series of hydraulic pistons of uniform size at the top for entering the moulds but of varying size at the bottom where they enter a common hydraulic chamber. The varying pressures are thus obtained automatically and the pistons operated by a single hydraulic control. The pistons are withdrawn after each operation and the moulding plate turned to bring the next moulds into position.—H. H.

Waste from coal-mining and from coking installations; Utilisation of —— by mixing with coal sludge. C. Hilgenstock. Ger. Pat. 272,852, Dec. 3, 1912.

THE sludge obtained in coal-washing plants is made to flow upwards through a filtering bed of the dry waste from coal mining or from coking installations.—A. S.

Distillation of coal. J. Stephenson, Salisbury. Eng. Pat. 13,104, June 5, 1913.

THE coal is continuously charged into and the coke discharged from a series of vertical retorts heated by a continuous supply of a predetermined proportion of water-gas from a pair of water-gas generators. The remaining portion of the water-gas is carburetted. The producer gas obtained from the water-gas generators during the "blow" period is burned in a chamber provided with a number of cross flues in which the air used to burn the water-gas is preheated. The hot products of combustion of the producer gas also serve to heat the flue or flues in which the water-gas is carburetted.—W. H. C.

Distilling coal in large charges; Process of —— and apparatus therefor. H. Breuillé. Second Addition, dated Nov. 10, 1913, to Fr. Pat. 435,189, Oct. 13, 1911 (this J., 1912, 323).

BENEATH the retorts is a channel provided with a conveyor for removing the ash so that all manual labour is avoided. —W. H. C.

Coke ovens; Process and apparatus for destroying fumes from —— during discharging and charging. F. J. Collin. Fr. Pat. 466,071, Dec. 11, 1913.

THE gas-outlet pipes of coke ovens are connected by elbow pipes with a channel passing through the masonry above the ovens and leading to the main chimney. This channel is opened when the ovens are being charged; the gases in the ovens are drawn into the channel, and are burnt by air admitted for that purpose.—H. H.

Gas-producers. J. A. Weil, Stockton-on-Tees. Eng. Pat. 4452, Feb. 20, 1914.

THE cylindrical portion of the rotary grate of a gas producer is set obliquely and is formed with a corrugated periphery to crush the ash and facilitate its discharge. —W. H. C.

Gas; Apparatus for use in manufacturing ——. J. E. Cochran, Assignor to The National Gas Process Co., Elkhart, Ind. U.S. Pats. 1,096,223 and 1,096,224, May 12, 1914.

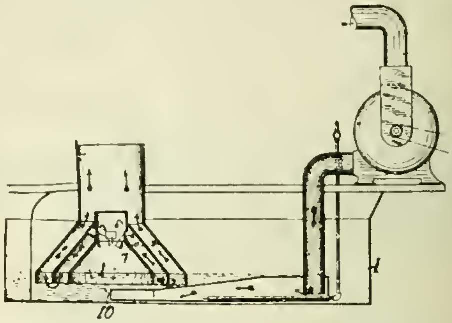
(1) THE gas is passed in succession through a number of compartments formed in a chamber by means of partitions, the first two compartments containing agents for removing impurities and the others, through which cooling tubes pass, serving as condensing chambers. Staggered baffles are arranged in the condenser compartments to force the gases into contact with the cooling tubes. (2) The condensing chambers are replaced by a single chamber provided with hollow shell-like baffles projecting into it so as to form a tortuous and narrow passage for the fluid. A cooling medium is circulated through the baffles.—H. H.

Gas process and product. W. O. Snelling, Pittsburgh, Pa., Assignor to Consolidated Liquid Gas Co., Chicago, Ill. U.S. Pat. 1,096,797, May 12, 1914.

ACETYLENE is forced under pressure into a vessel partly filled with liquefied propane, butane and ethane, and the mixture stored. When the pressure is released, the paraffin hydrocarbons vaporise with the acetylene and escape in admixture therewith.—H. H.

Gas or smoke washer. O. M. Foster, Elkhart, Ind., Assignor to American Smoke Washing Co., Cleveland, Ohio. U.S. Pat. 1,096,501, May 12, 1914.

THE gas or smoke is delivered from the open end of the pipe, 10, beneath a series of concentric hoods, 7, 8, 9, the lower edges of which dip into the washing liquid contained in the vessel, 1. The innermost hood, 7, is open at the top, the next, 8, closed and the third open and connected with the stack. The smoke is thus compelled to bubble twice through the washing liquid.—W. H. C.



Briquettes of coke dust alone or mixed with wood waste. J. Alexander, Altona, Germany. Eng. Pat. 16,838, July 22, 1913.

SEE Fr. Pat. 461,065 of 1913; this J., 1914, 67.—T. F. B.

Briquettes; Manufacture of ——. C. Fohr, Munich, and E. Kleinschmidt, Frankfort on Maine, Germany. Eng. Pat. 17,519, July 30, 1913. Under Int. Conv., Aug. 2, 1912.

SEE Ger. Pat. 263,158 of 1912; this J., 1913, 901.—T.F.B.

Gas-producer. C. Whitfield, Sydenham. U.S. Pat. 1,096,774, May 12, 1914.

SEE Eng. Pat. 1117 of 1913; this J., 1914, 190.—T. F. B.

Gas washer or scrubber. W. J. Fiddes, Tottenham. Eng. Pat. 13,813, June 14, 1913.

SEE U.S. Pat. 1,095,835 of 1914; this J., 1914, 585.—T.F.B.

Generator gas, water gas, and the like; Purifying apparatus for ——. Berlin-Anhaltische Maschinenbau-Akt.-Ges., Berlin. Eng. Pat. 28,389, Dec. 9, 1913. Under Int. Conv., Dec. 11, 1912.

SEE Ger. Pat. 271,122 of 1912; this J., 1914, 472.—T.F.B.

Process of treating sulphur-bearing materials. Eng. Pat. 21,385. *See* VII.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Acetic acid; Manufacture of —— by the destructive distillation of woody matters. G. Calvert, London. Eng. Pat. 10,687, May 6, 1913.

COFFEE husks or the like are heated in a continuous retort provided with a screw conveyor and the gaseous products of distillation are drawn off and treated for the recovery of acetic acid and then returned to the furnace where they are burned to assist in the heating of the retort.—W. H. C.

Wood; Process for the continuous distillation of ——. E. J. J., B. O. A., and O. A. R. Pampe. Ger. Pat. 272,725, Oct, 24, 1911.

A DEFINITE temperature is maintained in the still by means of a diaphragm-regulator. The regulator is connected with a rectifying column, dephlegmator, and oil separator in such a manner that when the temperature of the distillation gases falls, further heat is applied by means of a closed heating coil, whilst when the temperature rises too high, a quantity of the lighter and lower-boiling oils is run into the still from the oil separator.—T. F. B.

Ammonia from the products of the destructive distillation of coal or the like; Direct recovery of ——. C. Still, Recklinghausen, Germany. Eng. Pat. 28,215, Dec. 8, 1913. Addition to Eng. Pat. 28,072 of 1912, dated Dec. 6, 1911 (this J., 1913, 590).

Between the reheating apparatus in the principal patent (*loc. cit.*) and the intermediate cooler, a gas exhauster is provided, which serves for imparting motion to the gases within the plant, and an additional final cooler is arranged behind the ammonia saturator. A certain volume of the ammonia-freed gases is returned to the main gas current at a point between the cooling and reheating stages, whereby the volume of gases to be reheated is augmented and their capacity for saturation with aqueous vapour enhanced.—O. R.

Heating rotary tubular kilns; Method of ——. W. Engelhardt. Fr. Pat. 466,347, Dec. 18, 1913. Under Int. Conv., Dec. 30, 1912.

Liquid fuel is forced under pressure through parallel or converging jets into the end of the kiln which is obstructed or narrowed at a point somewhat in advance of the nozzles so that the fuel, and the air drawn with it, are thoroughly mixed at this point and a zone of intense combustion produced.—H. H.

III.—TAR AND TAR PRODUCTS.

m-Anisidine and dimethyl-m-anisidine. F. Reverdin and A. de Luc. Ber., 1914, **47**, 1537—1545.

To prepare *m*-anisidine, $C_6H_4(OCH_3).NH_2$, a solution of commercial *m*-aminophenol (110 grms.) in a mixture of water (100 c.c.) and glacial acetic acid (70 c.c.) was shaken with acetic anhydride (100 c.c.) and kept at the temperature of the water-bath for half-an-hour. On cooling, the acetyl derivative separated. This (152 grms.) was dissolved in an aqueous solution (300 c.c.) of sodium hydroxide (50 grms.) and well shaken with methyl sulphate (100 grms.) added in small portions. The yield in each of these two operations was well over 90% of the calculated amount. The resulting acetyl-*m*-anisidine was crystallised from 50% alcohol and hydrolysed by heating for 20 mins. on the water-bath with its own volume of hydrochloric acid (2 : 1). On pouring the product into water and rendering alkaline with ammonia, *m*-anisidine was obtained as an oil of b. pt. 243° C. Several salts and derivatives are described; *m*-anisidine-azo-β-naphthol forms red needles. Dimethyl-*m*-anisidine, $C_6H_4(OCH_3).N(CH_3)_2$, was prepared by gradually adding *m*-anisidine (12 grms.) to methyl sulphate (24 grms.) and subsequently heating for an hour on the water-bath. The product was poured into sodium hydroxide solution and to the separated base was added acetic anhydride (20 c.c.) in small portions to acetylate the primary and secondary base contained in the mixture. After warming for an hour the solution was neutralised with sodium carbonate and distilled with steam. Dimethyl-*m*-anisidine, boiling at 237° C., was thus obtained n a 75% yield. The nitration of this base is described, he chief products being 4.6-dinitrodimethyl-*m*-anisidine and 3-methylnitramino-4.6-dinitro-1-anisol.—J. R.

Cyclic hydrocarbons; Hydrogenation of —— *by means of sodammonium* ——. P. Lebeau and M. Picon. Comptes rend., 1914, **158**, 1514—1517.

odium, (2—10 atoms), was dissolved in a solution of aphthalene in anhydrous liquid ammonia. The action roceeds best under pressure at 15° C. The resulting roducts were sodamide, tetrahydronaphthalene, (90% ield), and a considerable proportion of an unidentified solid compound, $(C_{20}H_{18})$, which boiled with decomposition at 400 C., producing, apparently, a mixture of $C_{10}H_{10}$ and $C_{10}H_{12}$.—J. L. F.

Patents.

Sulphophenol-o-carboxylic acids; Process for producing compounds containing derivatives of ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 466,236, Dec. 16, 1913. Under Int. Conv., Feb. 17, 1913.

The sulphochlorides of aromatic *o*-hydroxycarboxylic acids are condensed with ammonia, amines, aminophenols, aminonaphthols, or their sulphonic or carboxylic acids or other derivatives. For example, salicylsulphamide, $HOOC(HO).C_6H_3.SO_2NH_2$, is obtained by the action of aqueous ammonia on the *p*-sulphochloride of salicylic acid. The products may be used in the preparation of dyestuffs.—T F. B.

Anthraquinone-α-nitriles; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 271,790, Feb. 18, 1913.

α-Halogen-anthraquinones are heated with copper cyanide in presence of an indifferent solvent, to produce anthraquinone-α-nitriles.—T. F. B.

4.4′-Diaminodibenzyl sulphide and its derivatives; Process for preparing ——. Chem. Fabr. vorm. Weiler-ter-Meer. Ger. Pat. 272,292, Nov. 1, 1912.

Aromatic amines or their homologues or substitution products with free *p*-position to the amino group or groups (aniline, ethylaniline, *o*- or *m*-toluidine, *o*-chloroaniline, metanilic acid, *m*-phenylenediamine, or α-naphthylamine) are treated with formaldehyde and an alkali thiosulphate in presence of an acid. The products are derivatives of 4.4′-diaminodibenzyl sulphide, $(NH_2.C_6H_4.CH_2)_2S$.
—T. F. B.

Acetoacetanilide-p-carboxylic acid; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 272,530, May 15, 1913.

Acetoacetanilide-*p*-carboxylic acid, which is a valuable azo dyestuff component, is obtained by saponifying its esters with caustic alkalis; no other decomposition of the molecule takes place.—T. F. B.

Acetoacetanilide; Process for preparing derivatives of ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 273,321, May 10, 1913.

Acetoacetanilide-*p*-carboxylic acid esters are obtained by heating *p*-aminobenzoic esters with acetoacetic ester, either alone or in presence of a diluent. The yields are good, whereas when the isomeric aminobenzoic esters are used, the reaction is very incomplete.—T. F. B.

Acridine derivatives from aminohydroxynaphthalenesulphonic acids; Process for preparing ——. Farbwerke vorm Meister, Lucius, und Brüning. Ger. Pat. 272,612, Dec. 6. 1912.

1-Aminohydroxynaphthalenesulphonic acids which have a free 2-position or 2-aminohydroxynaphthalenesulphonic acids with a free 1-position are treated with a tertiary aromatic amine and formaldehyde in presence of dilute mineral acid. The properties and composition of the products indicate that they are *p*-dialkylamino-*ms*-phenyldihydroxynaphthacridines.—T. F. B.

Condensation products of the anthraquinone series; Process for preparing nitrogenous ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 272,613, Dec. 14, 1912. Addition to Ger. Pat. 270,790 (see this J., 1914, 475).

α-Halogenanthraquinones or their derivatives or substitution products are heated with salts of aromatic glycines, preferably in presence of substances which combine with acids (acetates), under pressure to a high temperature (*e.g.* 160°—170° C.). The products are identical with those obtained according to Ger. Pat. 270,789 (this J., 1914, 474).—T. F. B.

Condensation products of the anthraquinone series; Process for preparing nitrogenous ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 272,614, Dec. 15, 1912. Addition to Ger. Pat. 265,725 (see this J., 1913, 1060).

α-Arylaminoanthraquinones, or the acridine compounds derived from them, are melted with naphthols and zinc chloride.—T. F. B.

Anthraquinone; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pats. 273,318, Dec. 14, 1912, and 273,319, Feb. 11, 1913.

(1.) Anthracene is oxidised to anthraquinone by means of iron chlorate or a mixture of an alkali chlorate and an iron salt. (2.) The chlorates or salts of other metals which can exist in the bivalent or tervalent form, are used to oxidise anthracene. In this and the previous patent, alkaline-earth chlorates may be used instead of alkali chlorates. —T. F. B.

Anthraquinone-N-1.1′-oxazine; Process for preparing ——. Farbwerke vorm. Meister, Lucuis, und Brüning. Ger. Pat. 273,444, March 20, 1913.

Anthraquinone-N-1.1′-oxazine is prepared by treating with condensing agents the 2-methoxy-1.1′-dianthrimide obtained by the action of 1-chloro-anthraquinone on 1-amino-2-methoxyanthraquinone (see also Ger. Pats. 266,945 and 266,946; this J., 1913, 1151).—T. F. B.

Amino-derivatives of anthraquinone; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 273,810, July 11, 1913. Addition to Ger. Pat. 267,212 (see this J., 1913, 1151).

Anthraquinone-1-sulphonic acid, anthraquinonedisulphonic acids, or derivatives of anthraquinonesulphonic acids are converted into the corresponding amino derivatives by treatment with ammonia in presence of a barium compound which will combine with the free sulphurous acid liberated during the reaction.—T. F. B.

IV.—COLOURING MATTERS AND DYES.

Thujin. A. G. Perkin. Chem. Soc. Trans., 1914, **105**, 1408—1413.

Thujin, isolated by Rochleder and Kawalier in 1858 (Wien. Akad. Ber., **29**, 10) from the green portions of the *Arbor vitæ* (*Thuja occidentalis*), is found to consist of quercitrin, with a trace of another glucoside, also probably of the flavonol group, whilst thujetinic acid is composed mainly of quercetin. Thujigenin is not regarded as a definite compound.—F. Sodn.

Santalin; Researches on ——. *Part II.* J. C. Cain, J. L. Simonsen, and C. Smith. Chem. Soc. Trans., 1914, **105**, 1335—1342. (See this J., 1912, 580.)

Molecular weight determinations by Barger's method indicated $C_{30}H_{28}O_{10}$ as the formula of santalin. Ethylcarbonatosantalin, $C_{30}H_{26}O_{10}(COOC_2H_5)_2$, was prepared by treating an alkaline solution of santalin with ethyl chloroformate. After purification by dissolving in ethyl benzoate and precipitating with benzene, it formed a reddish-brown powder, which could be hydrolysed with the production of santalin by warming with dilute potassium hydroxide. It was not acted upon by diazomethane and could not be further methylated. Santalin monomethyl ether, $C_{28}H_{20}O_6(OCH_3)_4$, was formed during the methylation of santalin and melted at 248°—250° C. It was insoluble in alkalis and was not acted upon by the usual hydroxyl reagents. Similarly to the dimethyl ether it gave a mixture of anisic and veratric acids on oxidation with alkaline permanganate solution. Nitrosantalin monomethyl ether, $C_{28}H_{18}O_4(NO_2)_2(OCH_3)_4$, was purified by dissolving in acetic acid and precipitating with water. It was an amorphous brown powder, soluble in alkalis and not melting below 300° C. Oxidation of nitrosantalin dimethyl ether yielded anisic acid, 4-nitro-2.3-dimethoxybenzoic acid and two other acids. It was concluded that the skeleton formula of santalin might be that of a dianthracene derivative. —F. Shdn.

Datiscetin; The constitution of ——. J. Leskiewicz and L. Marchlewski. Ber., 1914, **47**, 1599—1600.

From the products of the oxidation of datiscetin (a colouring matter present in *Datisca Cannabina*) with bromine, bromosalicylic acid, and tetrabromophloroglucinol were isolated. Since the substance is an isomeride of luteolin, and yields tetrabenzoyl and acetyl derivatives, these results are in agreement with the conception of datiscetin as 1.3.1′-trihydroxyflavonol.—G. F. M.

Indigo production in India. Rept. on the Progress of Agriculture in India for 1912–13. [T.R.]

The area under indigo in India in 1912 declined by nearly 20% to 214,500 acres, the output of dye declined by 21% and the price by 5·4%. The reduction of area is probably due to some extent to declining yield as well as to falling prices, the crop having been affected by a condition which seriously reduces the yield of "khoontics" and the production of seed, in the Java plant.

The Bihar Planters' Association having found itself unable to continue its subscription to the maintenance of the Sirseah Research Station, the latter has been closed.

It has been agreed that the most efficient methods of manufacture now in vogue in Bihar certainly extract within 30% of the possible amount of the colouring principle and that the present state of the industry does not justify further search for improved methods which would be likely to promise at best a further 15% of outturn in return for considerable capital expenditure on reorganisation of plant. It has consequently been decided that the improvement of yield by a botanical study of the crop and by selection of the best type of plant offers the best chance of success, and this work is being undertaken at Pusa.

Patents.

Vat [anthracene] colouring matters; Production of —— J. Y. Johnson, London. From Badische Anilin un Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng Pats. 12,817 and 27,010, June 2 and Nov. 24, 1913.

A nitro or amino derivative of normal or *iso*-dibenz anthrone is treated with a "reactive" chloride, viz., alu minium chloride, antimony pentachloride, phosphoru trichloride, or phosphorus pentachloride. The reaction i preferably carried out in presence of nitrobenzene. Th products give grey dyeings which are faster towards hypo chlorite solutions than the dyeings obtained from th known grey dyes of this class. (Reference is directed i pursuance of Sect. 7, Sub-sect. 4, of tho Patents an Designs Act, 1907, to Eng. Pat. 22,519 of 1905; this J 1906, 634.)—T. F. B.

Azo dyes containing an arylsulphonic ester group; Manu facture of ——. Anilinfarben- und Extract-Fabr. vorm J. R. Geigy, Basle, Switzerland. Eng. Pat. 30,05 Dec. 31, 1913. Under Int. Conv., Jan. 2, 1913.

The arylsulphonic esters of aminophenols (other than th of o-aminophenol) are used for the production of monoa or primary or secondary disazo dyestuffs. The dyestu have a great affinity for wool in neutral solutions, t shades produced being fast to milling, whilst the dyein on silk are fast to water. Their lakes are very fast sublimation. For example, orange-red dyestuffs are p duced from the *p*-aminophenyl ester of *p*-toluenesulphon acid after diazotisation and combining with β-naphtho by combining the diazo compound with 1-phenyl-3-methyl-5-pyrazolone, yellowish green dyestuffs are obtained A blue-black dyestuff is obtained by diazotising the *m*-aminophenyl ester of *p*-toluenesulphonic acid, combining with 1.8-aminonaphthol-3.6-disulphonic acid in acid solution, and combining this product in alkaline solution with diazotised *p*-aminophenyl ester of *p*-toluenesulphonic acid.—T. F. B.

Azo dyestuffs; Production of new diazotisable ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 465,794, Dec. 5, 1913. Under Int. Conv., Jan. 7 and June 28, 1913.

Dyestuffs which give yellow shades when developed with β-naphthol are obtained by combining the diazo compounds of nitro-(acetylamino-)arylacidyl derivatives of aromatic diamine-sulphonic or carboxylic acids with the pyrazolones or pyrazolone-carboxylic acids derived from aminothiazoles, *e.g.* dehydrothiotoluidine or Primuline, and afterwards reducing (saponifying) the nitro-(acetylamino-)group. Examples of the first component are nitro-(acetylamino)-benzoylphenylenediamine-sulphonic or -carboxylic acid, or the corresponding derivatives of benzidinesulphonic acid, diaminostilbenedisulphonic acid, etc.—J. B.

Indigoid dyestuffs; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 273,536, Aug. 15, 1912.

Derivatives of 2.3-naphthisatin halogenated in the naphthalene nucleus, and in which the α-keto oxygen is replaced by chlorine or an anilino or similar group, are condensed with components necessary for the formation of indigoid dyestuffs.—T. F. B.

Vat dyestuffs analogous in constitution to indirubin; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 273,537, Aug. 30, 1912.

Halogenated 2.3-naphthisatins are condensed with oxythionaphthene, indoxyl, or analogous compounds containing the group, $CH_2.CO$, or their substitution products.—T. F. B.

Indigo vat; Preparation suitable for the ——. A. Schmidt and A. Steindorff, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,096,060, May 12, 1914.

See Eng. Pat. 17,045 of 1911; this J., 1912, 808.—T.F.B.

Sulphurised dyes and process of making same. H. Heimann, Dessau, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 1,096,715, May 12, 1914.

See Fr. Pat. 454,782 of 1913; this J., 1913, 863.—T. F. B.

Azo dyestuffs. H. Jordan and W. Neelmeier, Leverkusen. Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,097,231, May 19, 1914.

See Fr. Pat. 457,840 of 1913; this J., 1913, 1004.—T. F. B.

Vat [anthracene] dyestuffs; Green —— and process of making same. B. Mayer, Assignor to Soc. of Chem. Industry in Basle, Switzerland. U.S. Pat. 1,097,343, May 19, 1914.

See Ger. Pat. 261,557 of 1912; this J., 1913, 822.—T. F. B.

Azo dyestuffs containing arylsulphonic ester groups; Process for preparing ——. Fabriques de Couleurs d'Aniline et d'Extraits ci-dev. J. R. Geigy. Fr. Pat. 466,161 Dec. 13, 1913. Under Int. Conv., Jan. 2, 1913.

See Eng. Pat. 30,055 of 1913; preceding.—T. F. B.

Manufacture of pigments. Eng. Pat. 20,106. *See* XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Paper and paper yarns; Dry and wet strengths of ——. C. Beadle and H. P. Stevens. Chem. News, 1914, **109**, 242—244.

The strongest Swedish "kraft" papers used for the manufacture of paper yarns show a tensile breaking length in the machine direction of over 9 km.; papers made from Hedychium for the same purpose show over 10 km. When thoroughly wetted, the strength of the Swedish papers either disappears altogether or is reduced to a negligible quantity (highest 0·58 km.); the strength of wet Hedychium papers is still considerable (1·58 km.). The modern process of twisting paper yarns from the finished paper, subsequently moistened, results in a decrease of the dry strength, the yarns from the Swedish papers showing an average breaking length of 6·89 km. and those from Hedychium papers 7·37 km. On the other hand, the strength of thoroughly wet paper yarn is very much greater than the strength of the original paper in the wet state. Yarns from the Swedish papers showed a wet strength of 4·18 km. on the average, and yarns from Hedychium, 4·90 km. This increase of wet strength as between paper and paper yarn is due to the twisting of the strips. Yarn made in the old way, by twisting strips without drying and finishing the paper, gave inferior results, both dry and wet. In the manufacture of yarn, the general rule is to produce a paper of a substance of 40—44 grms. per sq. m. and to vary the count of the yarn by varying the width of the strips.—J. F. B.

Sulphite pulp waste lyes; Disposal of ——. Lassar-Cohn. Chem.-Zeit., 1914, **38**, 657—658.

A report on the disposal of the waste lyes from two sulphite pulp mills in the neighbourhood of Königsberg. The effluent from one mill is discharged into the town sewers for irrigating the sewage fields. The admixture of the sulphite lyes with the sewage has produced a beneficial effect upon the crops, the large proportion of non-nitrogenous organic matter introduced by the lyes having an effect similar to that produced by the straw of farm-yard manure when used in conjunction with town-sewage, great bacterial activity being thereby induced. The soluble sulphur compounds probably also play an important part, for it has been shown that electrolytically prepared phosphates are by no means so successful as ordinary superphosphates, owing to the absence of calcium sulphate. The waste lyes from the other mill, situated at the mouth of the river, are carried out into the bay by tank-steamers and gradually discharged on the voyage. Here again, a beneficial result is recorded. The organic matters of the lye encourage the growth of the plankton, which attracts the fish, and the local fishery statistics show considerable increase. The question of profitable or even costless disposal of the lyes still awaits solution. The hygroscopic nature of the solid matters of the lyes makes them unsuitable for fuel briquettes, although small quantities are successfully applied for briquetting blast-furnace dust; the evaporation, however, is a difficult problem. Over 2 million kilos. of waste lyes are produced daily by the German pulp mills alone.—J. F. B.

Pseudo-tannins in sulphite-cellulose extracts. Moeller. *See* XV.

Detection of sulphite-cellulose extract. Gansser. *See* XV.

Patents.

Air-craft; Fabric [conducting electricity] for use in the manufacture of ——. R. Weil, Hanover, Germany. Eng. Pat. 23,932, Oct. 22, 1913. Under Int. Conv., Jan. 16, 1913.

Fabrics are treated with finely powdered graphite or with a mixture of rubber and graphite or with each successively. The conducting material is so applied or

brushed into the fabric that any movement of the latter independent of the conducting powder is impossible.
—J. F. B.

Fur and hair; Process for carotting ——. L. F. Paris, Paris. Eng. Pat. 5409, Mar. 3, 1914. Under Int. Conv., Mar. 5, 1913.

Fur or hair intended for the manufacture of felt is subjected to the action of nitrous anhydride, nitrosyl chloride, and a combination of nitrosyl chloride with a metallic chloride, *e.g.*, $ZnNOCl_3$, or a mixture capable of yielding such substances, together with a small excess of nitric and hydrodrochloric acids. Example: for a yellow carotting fluid, sodium nitrite and nitrate (300 grms. of each) are dissolved in 8 litres of water and 100 c.c. of commercial sodium hypochlorite solution added. A mixture consisting of nitric acid (sp. gr. 1·31), 1800 c.c.; hydrochloric acid, 500 c.c.; zinc chloride solution (sp. gr. 1·42), 350 c.c. is then stirred in and the skins treated in the ordinary way. A neutral salt, *e.g.*, a strontium or barium salt may be added to impart a lustre to the hair and precipitate any sulphuric acid present.—J. F. B.

Acetylcellulose solutions; Manufacture of ——. D. E. Reid. Assignor to Eastman Kodak Co., Rochester, N.Y. U.S. Pat. 1,095,999, May 5, 1914.

Acetylcellulose is dissolved in a solvent of low boiling point, mixed with a transparent non-oleaginous liquid which is not a solvent of cellulose, has a relatively high boiling point, is incapable of combining chemically with the cellulose or the solvent, and is non-inflammable. A solution of acetylcellulose in acetone, containing pentachloroethane in the proportion of 50—100% of the weight of the cellulose, is specified.—J. F. B.

Cellulose esters; Process for preparing ——. Knoll und Co. Ger. Pat. 272,121, Dec. 20, 1911.

Cellulose or an analogous compound is treated with an organic anhydride in presence of a salt of an ester-sulphuric acid. By adjusting the conditions of the reaction, acidylcelluloses soluble in chloroform and insoluble in acetone, or soluble in acetone may be obtained. Salts of the weaker bases are the more active catalysts.—T. F. B.

Pulp stuff; Apparatus for refining —— *for use in the manufacture of paper and the like.* T. H. Nash, St. Paul's Cray, Kent. Eng. Pat. 6876, Mar. 18, 1914.

The stuff is contained in a mixing chest having a well-shaped or semi-circular bottom in order to retain the heavy impurities which settle out; an agitator or zig-zag frame, mounted on a horizontal shaft in bearings situated in the ends of the chest, serves to keep the pulp well mixed. At a point above the lowest level of the chest is a sluice from which the stuff may be discharged in a regulated stream into a shoot, which delivers it down an inclined base, feeding the stuff between the roll and bed-plate of a beating engine. The beating apparatus may consist of one or several rolls, with their respective bed-plates, arranged consecutively on the inclined base. After treatment under the lowest beater-roll the stuff is returned to the mixing chest by a pump.—J. F. B.

Papers; Manufacture of opaque ——. A. D. Daigre and L. P. A. A. Bailleul, Paris. Eng. Pat. 7883, Apr. 3, 1913.

Opaque papers are made by the superposition of two or more layers of paper or partly manufactured moist paper coming from the paper-forming wires, the inner faces of the outside layers being coloured or coated and the whole united in a single sheet by suitable couch or press rolls. Preferably, the opaque or coloured layer is applied in the form of a very fine paper pulp introduced between two outer layers of paper so that under pressure it tends to fill up the pores of the inner surfaces of these layers. This opaque intermediate layer may be composed of a basis of magnesium carbonate with the necessary quantity of colouring matter and a small proportion of finely beaten rag or other stock.—J. F. B.

Paper; Manufacture of a flexible and waterproof material from ——. G. Magnasco, Genoa, Italy. Eng. Pat. 18,836, Aug. 19, 1913.

Sheets of paper are coated or impregnated with a mixture of animal glue, 25 parts; glycerin, 20; albumin, 10; camphor, 8; linseed oil, 10; sulphur, 7; water, 20 parts. The product is then tanned with formaldehyde or tannic acid on one side and a number of superposed sheets are compressed together. Tissues, threads or wires may be interposed between the sheets to strengthen the material. The composite sheet is afterwards again immersed in a tanning solution, dried and coated with paraffin wax or fats.—J. F. B.

Insects [in furs, skins, etc.]: Process of destroying ——. A. Erlenbach, Dessau, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 1,097,406, May 19, 1914.

See Fr. Pat. 442,719 of 1912; this J., 1912, 1026.—T. F. B.

Producing fermentable sugars [from cellulosic materials] U.S. Pat. 1,096,030. *See* XVII.

Purifying alcohol manufactured by distilling fermented sulphite liquor. U.S. Pat. 1,095,830. *See* XVIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Dyeing of wool; The theory of the ——. *Preliminary investigation of the constitution and dyeing properties of wool.* K. Gebhard. Z. angew. Chem., 1914, **27**, 297—307.

The presence of a primary amino group in wool is evident from the formation by the action of nitrous acid of a diazo compound and not a nitrosamine. In agreement with this is the absence of any reaction between the diazo-compound and phenol and sulphuric acid, also the normal combination of the diazo-compound with a series of azo-components and the fact that any condensation which has the effect of stopping up or removing an amino group has the effect of rendering wool undiazotisable. Treatment of diazotised wool with caustic soda causes a brown coloration and an increase in the acidic properties of the wool (loss of affinity for acid dyes) which suggests the formation of a triazone. The fact that wool has not yet been deamidised by decomposition of the diazo compound. which points to nitrosification rather than diazotisation, may be due either to ring formation between the diazo and the carboxyl groups or reduction to hydrazine. In support of the latter assumption is the violet colour which diazotised and boiled-out wool gives with caustic soda just like the hydrazinesulphonic acid of anthraquinone The hydrazinesulphonic acid of wool gives an orange coloration with zinc chloride, and it is suggested that ring formation takes place. The power of this condensatio product still to fix to a certain extent acid dyestuff suggests the weakly basic properties of a pyrazolone ring Treatment of wool with acetic anhydride seems to lead i the first instance to simple acetylation of the amin group. The wool loses its basic properties and its affinit for acid dyestuffs, whereas its affinity for basic dyestuffs i increased. Further action causes a strong brown coloration of the wool, due to ring (lactone, miacin, pyridone formation. Aldehydes which condense with the amin group, bisulphites which convert it into hydroxyl o sulphinic acid and oxidising agents which convert it int hydroxyl or cause ring (indazole) formation all have th effect of depriving wool of its basic functions as show by loss of affinity for acid dyestuffs and increased affinit for basic colours. Wool also behaves like a primar amine in forming salts, for instance with phosphotungsti acid. This salt formation is prevented by acetylation the wool but is not affected by esterification of the carbox group. The existence of a carbonyl group is shown b the action of hydroxylamine on wool. The affinity fo acid dyestuffs is thereby decreased, that for basic dyestuffs unchanged or increased. These effects can be heightened by inner salt formation, according to whether it takes place between the :C : NOH residue and the amino group or the carboxyl group, phosphotungstic acid furnishing an example of the former and aluminium acetate of the latter. That a carboxyl group is present in wool is shown by the formation of coloured metallic salts and by the fact that esterification with alcohol and sulphuric acid leads to a loss of all the acid properties of the wool. For complete reservation of wool against acid dyestuffs inner complex ring or salt formation involving both the amino and the carbonyl groups appears to be necessary, examples of which are the products of reaction of wool with pyrotartaric acid, urea or methylenedisalicylic acid, or the well-known tannin-stannous chloride reserve. The complex salt wool oxime-phosphotungstic acid is also an example. Of a large number of amino-acids examined in regard to their behaviour towards dyestuffs and mordants, only such as contained an aromatic nucleus, and particularly anthranoylanthranilic acid, approximated in their properties to wool, and it is concluded that a substance analogous to anthranoylanthranilic acid is the chief constituent of wool.—J. B.

Boric acid; The use of —— for souring. R. Weiss. Sealed note, No. 1366, dated Dec. 29, 1902. Report thereon by Th. Stricker. Bull. Soc. Ind. Mulhouse, 1914, **84**, 127—128.

A solution containing 3 grms. of boric acid per litre is used for souring after bleaching. There is not the same risk of tendering as when mineral acids are used, as a solution of boric acid can be dried on the fibre without risk. Ramie is said to be improved in appearance by this process.—J. B.

Barium aluminate as a mordant for cotton; The use of ——. L. Grenot. Sealed note, No. 1365, dated Dec. 25, 1902. Report thereon by M. Battegay. Bull. Soc. Ind. Mulhouse, 1914, **84**, 124—125.

Cotton is impregnated with a solution of barium aluminate and exposed to the air, whereby the salt is decomposed and alumina is deposited on the fibre. The process is applicable to Alizarin dyeing with or without oiling. —J. B.

Reserve; A new —— [under zinc dust and stannous chloride discharges]. A. Lehmann. Sealed note, No. 1381, dated Feb. 23, 1903. Report thereon by H. Schmid. Bull. Soc. Ind. Mulhouse, 1914, **84**, 125—127.

Precipitated sulphur is proposed as a reserve under zinc dust discharges, and sulphur in the form of hydrosulphite as a reserve under stannous chloride discharges. Hydrosulphite also gives good results in reserve printing under chlorate-prussiate black. The sulphur reserve is now obsolete since zinc and tin-salt have been replaced by hydrosulphite for discharge work, under which the usual reserves are nitrite and other oxidising agents or non-volatile organic acids.—J. B.

Patents.

Bleaching liquor; Process for the regeneration of ——. W. Mathesius and M. Freiberger. Fr. Pat. 466,121, Dec. 12, 1913. Under Int. Conv., April 2, 1913.

Bleaching kier liquor is regenerated by boiling with lime, filtering, treating with an oxidising agent (*e.g.* a hypochlorite), boiling and finally correcting the excess of oxidising agent, with bisulphite, for example.—J. B.

Singeing yarn and fabrics; Process and apparatus for ——. B. Szilard, Paris. Eng. Pat. 15,867, July 9, 1913. Under Int. Conv., July 10, 1912.

A quartz screen is interposed between the flame and the article to be singed.—J. B.

Mercerising yarn; Machines for ——. P. Hahn, Niederlahnstein a/R., Germany. Eng. Pat. 14,702, June 25, 1913.

The mechanism for stretching the yarn in mercerising machines of the type described in Eng. Pat. 22,235 of 1902 (this J., 1903, 993) is modified so as to avoid unnecessary stresses on the wearing parts of the machine during that part of the process in which the yarn is not under tension.—J. B.

Silk: Weighted —— and process of making it. E. Stern, Hanover, Germany. Assignor to Deutsche Gasglühlicht Akt.-Ges. (Auerges.), Berlin. U.S. Pat. 1,095,681, May 5, 1914.

Silk is treated with a solution containing a cerium salt rich in didymium and lanthanum, a zinc salt and a tin salt.—J. B.

Shifting hanks of yarn in dyeing; Apparatus for ——. Niederlahnsteiner Maschinenfabrik G. m. b. H. and P. Hahn, Niederlahnstein-on-the-Rhine, Germany. Eng. Pat. 16,738, July 21, 1913. Addition to Eng. Pat. 13,982 of 1911, dated June 13, 1910 (see Fr. Pat. 421,183; this J., 1911, 486).

A regulating mechanism is incorporated in the machine to enable adjustments to be made before starting, so that the beginning of the period, at which hanks must be turned and displaced on their carriers, can be regulated relatively to the intermediate period during which the hanks are only displaced. The regulation may be varied, according to the nature or the qualities of the yarn to be treated and the dye employed, thus enabling operations previously carried out by hand to be done automatically.—B. N.

[Developed] dyestuffs on the fibre by the one-bath method; Production of ——. A. G. Bloxam, London. From Chem. Fabr. Griesheim-Elektron, Frankfurt a/M., Germany. Eng. Pat. 9102, April 9, 1914.

Cotton goods are padded or printed with a caustic soda solution of an arylide of 2.3-hydroxynaphthoic acid and a nitrosamine salt (*e.g.*, that derived from *p*-nitraniline) and developed by passing through a solution of a weak acid or an acid salt, for example acetic acid or sodium bichromate. Brilliant red shades are produced. (See Eng. Pat. 13,766 of 1912; this J., 1912, 915.)—J. B.

Dyeing wool; Process of —— by means of furfural. A. and E. Lederer. Fr. Pat. 466,323, Dec. 17, 1913.

Wool is dyed yellow by treating it with a solution of furfural, the shade changing to a black on exposure or by the action of hydrochloric acid. Hydrochloric acid may be added directly to the bath or the process may be advantageously employed in connection with carbonising. The addition of metallic salts varies the shade and it is also possible to use the condensation products of furfural with phenols or other substances capable of undergoing the Perkin-Claisen condensation.—J. B.

Dyeing furs; Process for ——. L. Cassella und Co. Ger. Pat. 272,736, June 13, 1913.

Fur skins are chrome-tanned and simultaneously or previously treated with formaldehyde, then treated with chlorine and finally dyed with an acid wool dyestuff. The formaldehyde treatment reduces the amount of chloride of lime required to about one-third. If it is not desirable for the skin itself to come in contact with the formaldehyde, the fur alone is treated prior to tanning.—T. F. B.

Printing Alizarins; The preparation of esters of high molecular weight and their application in ——. Mollard and Cumet. Fr. Pat. 466,005, Dec. 10, 1913.

Substances of the ester type are produced by treating fatty acids of high molecular weight and having an alcoholic function (*e.g.*, ricinoleic acid) with acids other than sulphuric or formic, for example phosphoric, acetic, lactic or butyric acids. The new products are stable in the cold but decompose on heating in the presence of water with liberation of the fatty acid, which property enables them to be used for the direct printing of Alizarins without previous oiling.—J. B.

Brown or grey prints on vegetable fibres ; Process for producing fast ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 272,686, March 30, 1913. Addition to Ger. Pat. 271,252 (see this J., 1914, 480).

HEXAMETHYLENETETRAMINE is used in place of formaldehyde in the process described in the princ'pal patent. The printing colours prepared in this way are more stable than those made with formaldehyde.—T. F. B.

Lace and other similar goods, woven or other fabrics ; Coating —— *with metal.* E. A. and B. O. Holland, London. Eng. Pat. 9786, Apr. 25, 1913.

THE lace or other fabric is rendered waterproof by immersion in a solution of shellac or other varnish ; after drying, it is coated successively with a mixture of Oxford ochre and boiled oil, leaf-metal, and two layers of thin varnish or lacquer. The first treatment may be partly replaced by the application of rubber solution and parchment size. —J. F. B.

Hanks of yarn ; Apparatus for treating —— *with a liquid contained in a trough.* H. Hablützel, Zürich, Switzerland. Eng. Pat. 16,858, July 22, 1913.

SEE Fr. Pat. 460,829 of 1913 ; this J., 1914, 73.—T. F. B.

Mercerised cotton ; Production of ——. C. Rumpf, Berlin. Eng. Pat. 24,236, Oct. 25, 1913. Under Int. Conv., Oct. 28, 1912.

SEE Fr. Pat. 464,114 of 1913 ; this J., 1914, 418.—T. F. B.

Cotton ; Process for the treatment of ——. B. Teufer, Chemnitz, Germany. U.S. Pat. 1,097,377, May 19, 1914

SEE Fr. Pat. 463,073 of 1913 ; this J., 1914, 248.—T. F. B.

Printing gallocyanine dyestuffs on cotton ; Resist method of ——. Farbwerke vorm. L. Durand, Huguenin und Co., Basle, Switzerland. Eng. Pat. 8355, April 2, 1914. Under Int. Conv., May 2, 1913.

SEE Ger. Pat. 269,933 of 1913 ; this J., 1914, 418.—T. F. B.

Printing-colours. L. Schütze, Leipzig-Eutritzsch, and R. Fischer, Leipzig-Reudnitz, Germany. U.S. Pat. 1,096,198, May 12, 1914.

SEE Eng. Pat. 12,567 of 1913 ; this J., 1913, 1007.—T. F. B.

Finishing or dressing textile fabrics with soapy preparations. R. Weiss, Kingersheim, Germany. U.S. Pat. 1,097,493, May 19, 1914.

SEE Fr. Pat. 448,490 of 1911 ; this J., 1913 435.—T. F. B.

VII.—ACIDS ; ALKALIS ; SALTS ; NON-METALLIC ELEMENTS.

Potassium ferricyanide ; Electrolytic production of ——. G. Grube. Z. Elektrochem., 1914, **20**, 334—344.

IN the electrolysis of potassium ferrocyanide, good current yields of ferricyanide in solution were obtained when the anode and the cathode were separated by a diaphragm and the contents of the anode compartment well stirred. The current yield was best at low anode current densities, and was independent of the nature of the anode (nickel, platinum, iron, copper or lead peroxide). Maximum yield was obtained at about 50° C. ; above this temperature the alkaline solution of ferricyanide in the anode compartment suffered a purely chemical decomposition with formation of iron oxide which produced a non-conducting coat on the anode and thus lowered the efficiency of the cell. For the process to be of industrial value solid ferricyanide must be separated at the anode, since the alkaline liquid which accumulates there could not be evaporated without loss. By keeping the anolyte saturated with ferrocyanide, the ferricyanide was deposited in a pure finely crystalline form. When the anolyte had become so alkaline that oxygen began to be evolved it was regenerated by adding a suitable amount of potassium calcium ferrocyanide and passing in carbon dioxide : $CaK_2Fe(CN)_6+2KOH+CO_2=K_4Fe(CN)_6+CaCO_3+H_2O$. When nickel electrodes were used in the electrolysis it was necessary to exclude chloride from the electrolyte.—W. H. P.

Aluminium nitride ; The preparation of —— *from its elements.* J. Wolf. Z. anorg. Chem., 1914, **87**, 120—128.

PURE aluminium heated quickly to 2000° C. in a current of nitrogen and kept at this temperature for 60 mins. gave a product containing 33·9% N (theoretical 34·08%). Aluminium nitride dissociates in nitrogen at atmospheric pressure at about 1850° C. When heated in nitrogen at a pressure of 4·3 atmospheres, it melts at about 2150°—2200° C. It appears to exist only in the crystalline form.—T. ST.

Nitrides ; Dissociation pressures of some ——. R. E. Slade and G. I. Higson. Report of Brit. Assoc., 1913, 451.

VANADIUM, tantalum, or boron was heated in an unglazed porcelain boat *in vacuo*, nitrogen was admitted and allowed to react until the dissociation pressure of the nitride was attained, then some nitrogen was pumped off, and equilibrium established from the other side. The results obtained were :—

	Temperature.	Pressure.
	° C.	mm.
Vanadium	1203	Not greater than 0·2
„	1271	„ „ „ 1·5
Tantalum	1170	„ „ „ 0·4
Boron	1222	„ „ „ 9·4

—A. S.

Nitric oxide ; The compounds of —— *with ferrous and copper salts.* W. Manchot. Ber., 1914, **47**, 1601—1614. (See also this J., 1910, 563 and 1202.)

ON account of the reversibility of the reaction $FeSO_4+NO \rightleftharpoons FeSO_4\cdot NO$, only a portion of the iron in aqueous solutions of ferrous sulphate is combined with nitric oxide. In alcoholic solution, however, the absorption proceeds to completion, and by the addition of ammonium phosphate, potassium ferrocyanide, borax, or sodium arsenate, the insoluble ferrous-nitric oxide salt is precipitated, free from admixed ferrous salt. The product precipitated with ammonium phosphate had the composition $Fe(NO)HPO_4$ and formed a crystalline mass melting at 16° C. The ability of copper salts to combine with nitric oxide is limited to the bromide, chloride, and sulphate. In each case only 1 mol. NO is absorbed per atom Cu, and the products are extremely sensitive to water. The view previously put forward that the brown iron compounds are analogous to the basic ferric salts ($HO\cdot Fe:SO_4$, $NO\cdot Fe:SO_4$) is confirmed by the isolation of the phosphate above, and by the fact that a brown $(FeNO)^{\cdot\cdot}$ ion wanders to the cathode during electrolysis. In the previously described green compounds a (FeNO) group exists in the anion. The red iron-nitric-oxide compounds, and all the copper compounds gave negative results on electrolysis. Iron in stable complexes as the ferrocyanides or the tri-*a,a*-dipyridyl iron compounds is unable to combine with nitric oxide (or carbon monoxide, which is of importance with regard to hæmoglobin), but if one of the co-ordinated groups is less firmly bound, *e.g.* in $Na_3Fe(CN)_5NH_3$, the loosely bound group can be displaced. It is probable that in every case the nitric oxide first combines with the whole molecule by subsidiary valencies, since all condition-favouring diminution of dissociation favour the combination with nitric oxide. In dissociating solvents ion formation may then occur, the brown compounds being the limiting case.—G. F. M.

Ferrous-nitric oxide compounds; Lecture experiments with ——. W. Manchot. Ber., 1914, **47**, 1614—1616.

The reversibility of chemical action can be readily demonstrated by means of the reaction $FeSO_4+NO \rightleftarrows FeSO_4 \cdot NO$ (see preceding abstract). The displacement of the equilibrium to the right is shown by the complete absorption of nitric oxide by a concentrated ferrous sulphate solution in a nitrometer, and the reverse reaction by leading first nitric oxide, and then hydrogen into a dilute ferrous sulphate solution in a wash-bottle, when the intense brown colour first produced will, after 3—4 mins., have completely disappeared. Coloration and decolorisation can be effected in a similar manner, and still more rapidly, if a dilute alcoholic solution of cupric chloride be substituted for the iron solution.—G. F. M.

Radium preparations and mesothorium preparations of different ages; Distinguishing —— by the aid of their γ-radiation. O. Hahn. Strahlentherapie, 1914, **4**, 154—174. Chem. Zentr., 1914, I, 1779—1780.

If a solution of a radioactive salt be heated for several hours on the water-bath, with occasional boiling, the penetrating radiation falls to practically nil in the case of a radium salt, since the active deposit decomposes and the emanation is prevented from accumulating. If mesothorium be present, the penetrating radiation diminishes by an amount corresponding to the proportion of radium present. In freshly-prepared mesothorium products a radium-content corresponding to 25% of the total γ-radiation was found. In the following table the penetrating powers of the γ-rays from various radium and mesothorium preparations are shown, the figures representing the proportions of the total radiation passing layers of lead of increasing thickness, the portion passing a layer 3·3 mm. thick being taken as 100.

Thickness of lead, in mm.	Pure radium bromide.	Commercial mesothorium bromide.		Mesothorium bromide free from radium.	Radio-thorium.
		Freshly prepared.	About 2 years old.		
3·3	100	100	100	100	100
5	84·5	86·7	85·5	87·3	86·8
10	57·6	60·7	60·1	60·8	63·1
15	41·9	44	44·6	43·2	47·1
20	31·5	32·1	33·2	31·5	36·8
25	24·2	23·7	25·2	22·8	29·1
30	18·6	17·7	19·4	16·7	23·3
35	14·3	13·4	15·1	12·2	18·8
40	11·3	9·9	11·8	9·2	15·3
45	9·9	7·5	9·1	6·8	17·4

Curves plotted from results such as these afford a ready means of characterising various radioactive preparations. Attention is drawn to the great influence of the material of the electroscope: the action of the γ-rays was considerably greater in an electroscope made of lead than in one of aluminium or zinc, thus affording proof of the very strong secondary radiation of lead.—A. S.

Determination of ferrocyanides by oxidation with an alkali bromate. De Koninck and Joassart. *See* XXIII.

Patents.

Acid-resisting pipes and vessels for use in sulphuric acid concentration; Process of manufacturing ——. W. Strzoda, Schoppinitz, Germany. Eng. Pat. 26,732, Nov. 20, 1913.

An inner, acid-proof lining is separated from an outer, iron shell by a porous, acid-resisting cement, which is capable of reacting with iron and sulphuric acid, at places where leaks may occur, to form acid- and heat-resisting seals. Such a cement may be composed of fossil earth, barium sulphate, and sodium silicate, with or without the addition of iron powder.—O. R.

Drying liquids, gases and vapours [nitric acid]; Process of ——. Norsk-Elektrisk Kvaelstofaktieselskab. Fr. Pat. 465,504, Nov. 29, 1913. Under Int. Conv., Nov. 30, 1912.

The weak nitric acid is vaporised and the vapours passed up a tower supplied with concentrated sulphuric acid, so that only practically dry nitric acid vapour escapes from the top. To avoid irregular working due to the heat evolved by the absorption of water by the sulphuric acid, a portion of the latter is withdrawn from the lower part of the tower, passed through a cooler and returned higher up. The diluted sulphuric acid from the bottom of the tower is concentrated for use again but is first passed through an apparatus in which the nitric acid is expelled by a current of air, the vapours of nitric acid carried away being passed up the first tower.—W. H. C.

Hydrosulphites; Manufacture of anhydrous ——. J. Y. Johnson, London. From Kinzlberger und Co., Prague, Austria. Eng. Pat. 11,010, May 9, 1913.

Anhydrous hydrosulphites are prepared by heating sodium formate with sodium bisulphite or sodium pyrosulphite to 65°—70° C. in the presence of alcohol, of 70—90% strength, preferably with addition of sulphur dioxide or formic acid, or both.—O. R.

Sulphur-bearing materials; Process of treating ——. H. Koppers, Essen-Ruhr, Germany. Eng. Pat. 21,385, Sept. 22, 1913.

Sulphur-bearing materials, especially the residues from the purification of coal-gas, are passed continuously through a container, in which they are subjected to the action of steam and gases, heated to a temperature below that at which sulphur volatilises. The issuing gases are drawn through a saturator, for the absorption of the ammonia (which is formed and evolved in the container), and forced through a superheater back into the container. The object of the process is to remove organic matter, etc., from the material and render it more suitable for the production of sulphur dioxide for use in the manufacture of sulphuric acid.—O. R.

Aluminium nitride; Method of obtaining —— by heating alumina or aluminous materials and carbon in an atmosphere containing nitrogen. Soc. Générale des Nitrures, Paris. Eng. Pat. 23,740, Oct. 20, 1913. Under Int. Conv., Nov. 22, 1912.

A mixture of aluminous substances and carbon is blown, dropped, or passed in a state of suspension through a graphite tube, several metres high and 12 cm. in diameter, which is heated electrically to about 2000° C.—O. R.

Aluminium nitride; Preparation of —— in electric furnaces heated by the electric arc. Aluminium Industrie Akt.-Ges. Fr. Pat. 465,807, Dec. 6, 1913. Under Int. Conv., Dec. 7, 1912.

A mixture containing alumina and carbon is heated by the electric arc, and a plentiful supply of nitrogen or gas containing nitrogen is led directly into the flame through hollow electrodes, or is passed between the arc and the mixture, leaving the furnace at a somewhat lower level. The furnace (preferably of the shaft type) is provided with a cover, and the wall is pierced at about the level of the electrodes by channels directed downwards and normally closed, which communicate with a spherical cavity in the charge, formed around the electrodes during working. The channels serve for recharging and permit of working the charge, so that the reaction product (relatively pure aluminium nitride) may be regularly withdrawn through an opening at the bottom of the furnace.—F. Sodn.

Nitrogen compounds of aluminium and alkali or alkaline-earth metals; Manufacture of double ——. D. Peniakoff. Fr. Pat. 465,679, Feb. 11, 1913.

An alkali or alkaline-earth aluminate (or substance yielding such on heating), mixed with an amount of carbon equivalent to the combined oxygen present, is heated in a current of nitrogen or gas containing nitrogen, which is readily absorbed at a relatively low temperature. The double nitride thus obtained is treated for the production of ammonia or other nitrogen compound, with simultaneous recovery of aluminate, or of pure alumina and alkali or alkaline-earth compounds.—F. Sodn.

Zinc lyes; Treatment of ——. W. Buddeus, Charlottenburg, Germany. Eng. Pat. 25,967, Nov. 12, 1913. Under Int. Conv., Dec. 11, 1912.

Zinc lyes containing ferrous iron are treated with sufficient slaked lime to precipitate all the zinc and all the ferrous iron, the precipitate is dried by means of air, which oxidises all the ferrous to ferric hydroxide, and the dried mass is treated with sufficient acid to form the corresponding zinc salt only, all the zinc hydroxide being dissolved before the ferric hydroxide is attacked.—O. R.

Hydrogen peroxide; [Electrolytic] Manufacture of ——. H. Wade, London. From Henkel und Co., Düsseldorf, Germany. Eng. Pat. 754, Jan. 10, 1914.

In the electrolytic production of hydrogen peroxide, as described in Eng. Pat. 8582 of 1913 (this J., 1913, 791), the amalgamated gold cathodes are replaced by cathodes composed of silver or copper amalgam.—O. R.

Calcium cyanamide; Process and means for producing continuously ——. Dettifoss Power Co., Ltd., and J. H. Lidholm, London. Eng. Pat. 3546, Feb. 11, 1914. Under Int. Conv., Feb. 18, 1913.

Calcium carbide is fed continuously through an electrically heated, inclined, rotary tube furnace, into which nitrogen is injected under pressure. The furnace contains, in addition to a main channel, one or more longitudinal channels, and is provided with a system of injectors, which produce a circulation of the nitrogen, the flow of the gas in the main channel being in counter-current to the passage of the carbide, which moves from a hopper at the feed end, through the zone of highest temperature, to a collecting chamber at the delivery end.—O. R.

Nitrogen compounds derived from carbides [calcium cyanamide]; Manufacture of ——. J. H. Lidholm and Dettifoss Power Co., Ltd. Fr. Pat. 465,473, Nov. 28, 1913. Under Int. Conv., Feb. 24, 1913.

Nitrogen is supplied to a closed (preferably bell-shaped) furnace chamber, fitted with a movable hearth which may be lowered from the furnace and removed on rails. The charge is not allowed to come into contact with the walls of the chamber, but is introduced into a receiver on the hearth, before this is moved into position, or is fed in gradually through a device in the roof of the chamber. A second charge is introduced into the heated furnace, on a new hearth, as soon as the first has been withdrawn.—F. Sodn.

Aluminium-bearing materials; Treatment of ——. H. P. Bassett, Catonsville, Md. U.S. Pat. 1,095,306, May 5, 1914.

Clay, felspar, or the like, is heated with an equal weight of a mixture of sodium carbonate, 3, and sodium chloride, 2 parts, the soluble portion of the treated mass is extracted with water, carbonated, and the aluminous precipitate is separated. Caustic alkali is added to the remaining solution, to convert sodium and potassium bicarbonates into carbonates, and the solution sufficiently evaporated to separate sodium carbonate and chloride.—O. R.

Antimony oxide; Method of manufacturing ——. A. L. Stark, Assignor to The Enamel Company of America, Elyria, Ohio. U.S. Pat. 1,096,468, May 12, 1914.

A combustible mixture of air and hydrocarbon holding powdered antimony sulphide in suspension, is discharged into a chamber where it is ignited, the mixture of antimony oxide and sulphur dioxide produced is immediately cooled so as to prevent the formation of antimonic oxide, and the antimony oxide separated, *e.g.*, by passing the combustion products through a settling chamber and dust collector.—F. Sodn.

Radium, radioactive emanations, and other radioactive substances; Process of extraction, isolation, and concentration of ——. E. Ebler. First Addition, dated Dec. 4, 1913, to Fr. Pat. 440,236, Feb. 16, 1912 (this J., 1912, 723). Under Int. Conv., Dec. 11, 1912.

Adsorption is effected by means of hydrated manganese peroxide which may be formed *in situ* by reducing permanganate (preferably with manganese chloride), and the radioactive salt, extracted from the adsorption product, is redissolved, and the treatment repeated until the desired concentration of radium (with respect to barium, for instance) is effected.—F. Sodn.

Radioactive preparation. Radiogen-Ges. m. b. H. Fr. Pat. 466,015, Dec. 10, 1913. Under Int. Conv., Dec. 13, 1913.

A radioactive substance, of such a nature that its first decomposition product is the mother-substance of the emanation of the radioactive matter, is incorporated in a porous, inert vehicle. For example, radio-thorium, the first product of which, thorium X, gives rise to thorium emanation, may be used.—O. R.

Sodium chloride; Process of decomposition of ——. A. Helbronner. Fr. Pat. 465,350, Feb. 3, 1913.

Sodium chloride is subjected to the combined action of carbon and steam (or their reaction products) in the presence of metallic oxides (such as ferric oxide or alumina) which react with the sodium hydroxide formed to give such compounds as ferrites, aluminates, etc.—F. Sodn.

Ammonium nitrate; Manufacture of ——. Wulfing Dahl and Co. Fr. Pat. 465,683, Nov. 18, 1913.

Sodium nitrate (1 mol.), or a mixture containing alkali nitrate and other alkali or ammonium salts, is treated in aqueous solution with sufficient ammonium sulphate (at least 1 mol.), to convert all the alkali metal into alkali ammonium sulphate, and the ammonium nitrate formed is separated by fractional crystallisation from the less soluble double salt, or the solution is concentrated and extracted with alcohol or other solvent. Or, sodium nitrate and ammonium sulphate are allowed to interact in equivalent proportions, the double salt destroyed by heating (*e.g.*, to 119° C.), the solution concentrated until most of the sodium sulphate has separated, and the mother liquor, after adding more ammonium sulphate to convert the remaining sodium sulphate into double salt, is treated as above.—F. Sodn.

Separation of particles easily condensed or absorbed from those which are not easily condensed or absorbed, from mixtures of hot compressed gases. [Ammonia from hydrogen and nitrogen.] B. Lepsius. Fr. Pat. 466,102, Dec. 12, 1913. Under Int. Conv., Dec. 13, 1912.

The hot mixture of ammonia with the residual hydrogen and nitrogen coming from the contact apparatus is passed into the cylinder of a compressing pump where it expands and is cooled, at the same time doing work. The cooled mixture of gases is then passed through an absorbing or condensing apparatus and the ammonia separated. The residual hydrogen and nitrogen pass back into the othe end of the cylinder and are compressed, whereby the are raised to a suitable temperature and pressure for us again in the contact apparatus. Fresh supplies of hydrogen and nitrogen may be added to the residual gases and any deficiency of power is supplied from external sources.—W. H. C.

Ammonia ; Process for the catalytic production of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 466,303, Dec. 5, 1913. Under Int. Conv., Feb. 26, 1913.

In the synthesis of ammonia from nitrogen and hydrogen under pressure, the contact mass is cooled, *e.g.* by embedding in the mass a spiral cooler, through which a current of cold, compressed gases circulates.—O. R.

Ammonium sulphate from calcium carbonate muds containing it ; Extraction of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 466,302, Dec. 5, 1913. Under Int. Conv., Feb. 26, 1913.

Calcium carbonate slimes containing ammonium sulphate are filtered in an "immersion suction filter," comprising a number of submerged filtering elements, each consisting of two filtering surfaces mounted on a frame, and separated by a space from which conduits lead to a suction device.—O. R.

Nitrous gases ; Process for the absorption of ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Fr. Pat. 465,740, Dec. 4, 1913.

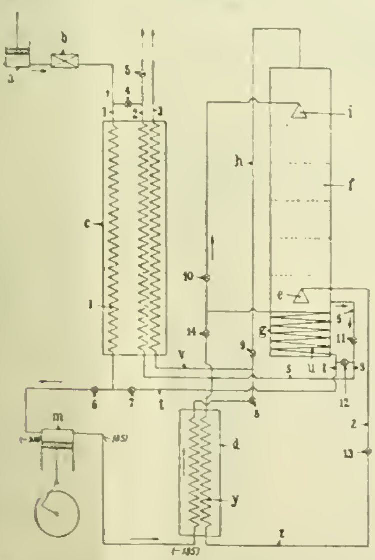
Dilute acid produced by absorption of nitrous gases is alternately neutralised (by limestone, for example) and employed for absorbing further quantities of the gases until any desired concentration of calcium nitrate is reached.—F. Sodn.

Colloidal silicic acid ; Process for the purification of liquids containing ——. H. W. de Stucklé. Fr. Pat. 465,817, Dec. 6, 1913. Under Int. Conv., Dec. 7, 1912.

Hydrofluosilicic acid, or one of its salts, is used to precipitate silica completely from its colloidal solutions, the separation taking place instantaneously at boiling temperature. A portion of the silica present may be converted into hydrofluosilicic acid by addition of a fluoride and a mineral acid, and used to precipitate the remainder.—O. R.

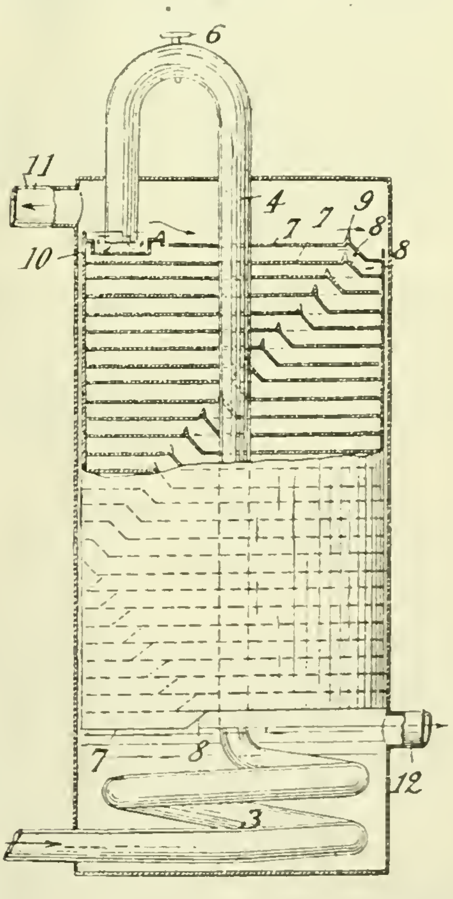
Liquefaction of air, with a view to its separation into its constituent elements ; Process and apparatus for the ——. G. F. Jaubert. Fr. Pat. 465,822, Feb. 14, 1913.

First phase : Air at about 25 atmospheres pressure is forced by the pump, *a*, (see Fig.), through the purifier, *b*, into the worms, 1, and 2, of the interchanger, *c*, the tap, 4, being open, and the tap, 5, closed. Passing downwards through 1, and by way of the open tap, 6 (tap, 7, being closed), into the expansion motor, *m*, which it enters and leaves at temperatures of about —100 C. and —185° C. respectively, the air passes into the liquefier, *d*, and through the open tap, 8, by way of the tube, *v*, into the worm, 3, of the interchanger. Taking the other course down the worm, 2, the air passes through the tap, 12, into the coils, *u*, of the vaporiser, *g*, where it is cooled by a shower of liquid air issuing from the rose, *e*. Leaving *u*, the air, now liquefied, passes by way of the tap, 14, into the worm, *y*, of the liquefier, *d*, and through *z* to the rose, *e*. The spray of liquid air falling on the coils, *u*, undergoes partial vaporisation, gaseous nitrogen ascending the column, *f*, and liquid oxygen collecting at its foot at *g*. *Second phase :* When the coils, *u*, are entirely submerged in liquid oxygen, which reaches nearly to *e*, the motor, *m*, is stopped, the taps, 4, 6, 12, 13, and 14, are closed, and the taps, 5, 7, 9, and 11, are opened. Air now passes down the worm, 1, only, through the tap, 7, and tube, *t*, into the coils, *u*, where it is liquefied, passing out to be expanded at 10, into the rose, *i*, from which it flows down and is rectified in the column, *f*. Nitrogen escapes at the top and passes through *h*, and 9, into the worm, 3, whilst oxygen flows through *s*, and 11, into the worm, 2, of the interchanger.—O. R.



Oxygen and nitrogen ; Process and apparatus for the separation of liquid air, by distillation only, into ——. Comp. Internationale de l'Oxygène. Fr. Pat. 466,315, Dec. 16, 1913. Under Int. Conv., Dec. 2, 1913.

Strongly cooled, compressed air passes upwards through the tube, 3, 4, and expansion-valve, 6, whereby it is liquefied. The liquid air overflows from the well, 10, and flows down over a spiral staircase, the surfaces, 7, of which communicate with one another by way of the inclined steps, 8, and are provided with rims, 9. The surfaces, 7



are of very thin, heat-conducting material, and the thin layers of liquid air, the thicknesses of which are determined by the rims, 9, are evaporated by the heat, which is furnished by the air ascending in 4 ; gaseous nitrogen rises upwards to escape at 11, and liquid oxygen descends and is collected at 12.—O. R.

Distilling acids ; Method of and means for ——. W. Ilof, Frankfort, Germany. Eng. Pat. 21,291, Sept. 20, 1913. Under Int. Conv., Sept. 20, 1912.

See Fr. Pat. 463,208 of 1913 ; this J., 1914, 421.—T. F. B.

Ammonium chloride ; Manufacture of ——. Berlin-Anhaltische Maschinenbau-A.-G. Abteilung Köln-Bayenthal, Germany. Eng. Pat. 11,312, May 14, 1913. Under Int. Conv., May 30, 1912.

See Fr. Pat. 457,681 of 1913 ; this J., 1913, 1009.—T. F. B.

Ammonium sulphate ; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 12,979, June 4, 1913.

See Fr. Pat. 462,487 of 1913 ; this J., 1914, 483.—T. F. B.

Hydrogen peroxide ; Process of producing ——. A. Pietzsch and G. Adolph, München, Germany. Eng. Pat. 13,544, June 11, 1913.

Nitrogen simultaneously with oxides of nitrogen ; Process of producing ——. M. Rohmer, Gersthofen, Assignor to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pats. 1,096,392 and 1,096,393, May 12, 1914.

See Fr. Pat. 453,845 and Eng. Pat. 28,737 of 1913 ; this J., 1913, 791 ; 1914, 483.—T. F. B.

Lead salts of acetic acid ; Manufacture of ——. F. J. Kalkow, Offenbach on Maine, Germany. U.S. Pat. 1,097,099, May 19, 1914.

See Eng. Pat. 29,048 of 1913 ; this J., 1914, 256.—T. F. B.

Manufacture of acetic acid by the destructive distillation of woody matters. Eng. Pat. 10,687. *See* IIb.

VIII.—GLASS ; CERAMICS.

Eye-preserving glass for spectacles ; Preparation of ——. Sir W. Crookes. Phil. Trans. Roy. Soc., 1914 [A. 509], 1—25.

The main object of the research was to prepare a glass which would cut off those rays from highly heated molten glass which damage the eyes of workmen, without obscuring too much light or materially affecting colours of objects seen through spectacles made of the glass. The screening properties of glass plates for ultra-violet, luminous, and infra-red radiations were investigated. Photo-spectrographs were taken, with exposures varying up to 3 hours, of the radiations from a glass tank in actual practice, the temperature at the melting end being 1500° C., and at the working end 1200° C. Infra-red rays being found in far greater abundance than ultra-violet, it is inferred that glassworkers' cataract must be ascribed principally to heat rays. A series of glasses was made by adding pure metallic oxides and earths as colouring or absorbing materials to a soda flux. Absence of striæ was obtained by repeated stirring with a platinum rod ; and freedom from air-bubbles, by leaving the glass in perfect repose for 1½ hours at the maximum temperature. After cooling for 12 hours, plates were cut, ground and polished to a thickness of 2 mm. By superposing on the radiation from a Nernst lamp the light from a high-tension discharge between poles of pure metallic uranium, a practically continuous beam extending from λ 2000 to λ 8000 was obtained, and the absorption of the glass plates recorded on a spectograph. Biotite (black mica) from Norway and "black amber" mica from Africa were found most effective in obstructing light while transmitting heat rays. Athermancy of various glasses by the readings of a thermometer bulb corresponded with the results obtained from a radiometer balance. The prepared plates were first tested in the spectrum apparatus to ascertain the upper limit of transmission of ultra-violet rays. They were next put into the radiometer balance, then tested in an opacity balance to ascertain the percentage of luminous rays transmitted, and finally their colour was registered in a Lovibond tintometer. The composition of the glasses selected for practical use, in percentages by weight, is as follows :—**150** : fused flux 90·00, cerium borate 8·13, $NiSO_4,7H_2O$ 0·07, U_3O_8 1·80 ; **158** : fused flux 89·75, cerium borate 8·13, Fe_3O_4 2·03, Cr_2O_3 0·09 ; **165** : raw flux 87·56, cerium borate 8·00, $FeSO_4,7H_2O$ 3·00, UO_3 0·55, NiO 0·09, Cr_2O_3 0·80 ; **187** : fused flux 83·0, $Ce(NO_3)_3,6H_2O$ 17·0 ; **197** : fused flux 79·00, $Ce(NO_3)_3,6H_2O$ 20·50, $NiSO_4,7H_2O$ 0·30, $CoSO_4,7H_2O$ 0·05, U_3O_8 0·15 ; **202** : flux 95·15, Fe_2O_3 4·75, $CoSO_4,7H_2O$ 0·10 ; **210** : fused flux 89·0, $FeSO_4,7H_2O$ 8·9, Cr_2O_3 1·3, carbon in fine powder 0·8 ; **217** : fused flux 96·80, Fe_3O_4 2·85, C 0·35 ; **221** : fused flux 80·0, $Ce(NO_3)_3,6H_2O$ 13·4, U_3O_8 6·6 ; **238** : raw flux 77·0, $Ce(NO_3)_3,6H_2O$ 23·0 ; **240** : raw flux 90, $FeC_2O_4,2H_2O$ 10 ; **246** : as 240 with a small quantity of red tartar and powdered wood charcoal to prevent oxidation ; **247** : raw flux 92·00, cerium borate 6·30, NiO 0·04, Fe_2O_3 1·60, Cr_2O_3 0·06 ; **248** : fused flux 94·60, $Ce(NO_3)_3,6H_2O$ 4·72, UO_3 0·30, NiO 0·30, $CoSO_4,7H_2O$ 0·08 ; **249** : fused flux 88·47, Fe_2O_3 1·50, $CoSO_4,7H_2O$ 0·03, $Ce(NO_3)_3,6H_2O$ 10·00 ; **250** : raw flux 88·00, cerium borate 5·00, $FeSO_4,7H_2O$ 4·15, U_3O_8 2·75, Cr_2O_3 0·10 ; **251** : raw flux 92·0, $FeSO_4,7H_2O$ 8·0 ; **252** : raw flux 72·60, $Ce(NO_3)_3,6H_2O$ 24·90, $CuSO_4,5H_2O$ 2·10, NiO 0·40 ; **253** : raw flux 88·5, fused black biotite 11·5. The last-mentioned glass has properties contrary to what might be expected from its biotite content ; it offers almost complete obstruction to heat rays. The transmissive powers of biotite itself appears to be due to iron protoxide. In the foregoing recipes the flux used has the composition : sand 61·00, anhydrous sodium carbonate 25·50, recrystallised sodium nitrate 5·00, precipitated calcium carbonate 7·20, borax 0·75, arsenic trioxide 0·55%. The optical properties of the glasses are shown in the following table :—

No.	Heat rays absorbed.	Absorbs violet and ultra-violet rays of wave length shorter than :	Luminous rays transmitted.	Colour.
	%		%	
150	37	3620	73	Pale yellow.
158	63	3700	54	Pale greenish yellow
165	38	3680	42	Pale yellowish green.
187	27	3650	99	Practically colourless
197	41	3800	45	Pale neutral tint.
202	83	3830	25	Neutral tint.
210	87	3620	30	Bluish green.
217	96	3550	40	Bluish green tinge.
221	39	3685	60	Faint yellow.
238	34	3610	71	——
240	88	3950	36	Smoky green.
246	98	3800	27·6	Sage green.
247	29	3620	71	Faint green.
248	47	3550	30	Neutral tint.
249	51	3550	63	Pale blue.
250	25	3685	74	Yellow, green tinge.
251	37	3550	89	Faint yellow.
252	47	3680	45	Faint bluish green.
253	94	3610	30	Sage green

Glasses Nos. 246, 217, 253, 240, 210, and 158 are most effective for cutting off heat rays, Nos. 240, 202, 246, 197, 158, 221, and 150 for absorbing ultra-violet rays, Nos. 187, 251, 250, 150, 247, and 238 for transmitting luminous rays, and Nos. 249, 197, 252, 165, 210, and 248 for reducing glare (of sun on chalk, snow, or sea).—H. H. S.

[*Zirconia crucibles*]. *Researches in the field of high temperatures. IV.* O. Ruff and G. Lauschke. Z. anorg. Chem., 1914, **87,** 198—208. (See also this J., 1914, 262, 593.)

Three grades of zirconium oxide were formed into crucibles, baked at temperatures varying from 1500° to 2400° C., and the shrinkage, loss of weight, and porosity determined. One grade consisted of the natural oxide and contained ZrO_2 83·53, SiO_2 11·48, Al_2O_3 0·58, Fe_2O_3 4·65%; the other two were obtained by precipitation and contained ZrO_2 98·73, SiO_2 0·95, Fe_2O_3 0·27 %. The first of these was ignited at 900°—1000° C., and the second for 10 hours at about 1400° C. The natural oxide gave good crucibles when baked below 1900° C. Above this temperature silica was volatilised and blisters were formed. The more strongly ignited prepared oxide was less plastic than the other and required an agglutinant, the best results being obtained with about 1% of dry starch; the addition of starch increased the porosity. The less strongly ignited oxide gave the greater shrinkage and the lower porosity. —T. St.

Enamel glazes free from lead and tin. A. Berge. Sprechsaal, 1914, **47,** 339—341. (See also this J., 1913, 142.)

Antimony compounds as a substitute for the costly tin oxide in producing opacity have not yet been unanimously condemned as poisonous. The following molecular formulæ are given for glazes fired at cone 010 with an addition of 7·5% Sb_2O_3, and found after ten weeks to be free from crazes :—

	1	2	3	4	5
SiO_2	2·8	2·0	3·0	3·2	3·0
Al_2O_3	0·25	0·2	0·3	0·1	0·2
B_2O_3	0·30	0·5	0·46	0·6	0·5
K_2O	0·5	0·2	0·3	0·1	0·2
CaO	0·5	—	0·27	0·2	0·15
Na_2O	—	0·25	0·2	0·3	0·25
MgO	—	0·1	—	0·23	—
BaO	—	0·45	—	—	0·1
SrO	—	—	0·3	0·2	0·3

—H. H. S.

Enamels ; Covering power of clouding agents for ——. R. Vondracek. Sprechsaal, 1914, **47,** 341—342.

A new class of substances for producing opacity in glazes has appeared in water- and alkali-containing forms of the usual reagents, the oxides of tin, zirconium and titanium. The increased power of the new products, which may contain for example 3% Na_2O and 10% H_2O, cannot be explained on chemical grounds alone, but is probably due to the oxide being in the colloidal state of a gel, the water being absorbed. This hypothesis explains also the fact that the presence of alkali may be injurious to the covering power of tin oxide, when the latter has been "dead burnt," in which case it loses its power of absorption and gel formation.—H. H S.

Patents.

Glass furnace. P. Bourdu. First Addition, dated Nov. 11, 1913, to Fr. Pat. 418,482. July 21, 1910 (this J., 1911, 87).

In place of separate wells to receive the molten glass in case of breakage of a pot, as described in the chief patent, a circular gallery with the bottom sloping downwards to the middle is provided.—H. H. S.

Ceramic materials ; Manufacture of ——. W. J. Mellersh-Jackson, London. From H. H. Randolph, Chicago. Eng. Pat. 8748, April 14, 1913.

See Fr. Pat. 456,837 of 1913 ; this J., 1913, 1069 —T. F. B.

[*Packing material for*] *Electric batteries and accumulators.* Eng. Pat. 16,681. *See* XI.

IX.—BUILDING MATERIALS.

Portland cement ; The presence of combined nitrogen in ——. V. Kratochvil and G. Weissenberger. Oesterr. Chem.-Zeit., 1914, **17,** 116—118.

Portland cement was boiled for half an hour with a 30% solution of caustic alkali, and the evolved ammonia determined. An average of 0·00025% of combined nitrogen was found, and control determinations with powdered granite, to which were added aluminium nitride, calcium cyanamide, and calcium cyanide, indicated that aluminium nitride was the most probable source of the combined nitrogen.—O. R.

Cements ; Influence of common salt on various ——. A. O. Passow. Tonind.-Zeit., 1914, **38,** 995—997.

Cement made from granulated, vitreous blast furnace slag with Portland cement, and Passow's cement (a mixture of vitreous and devitrified slag) were found to be improved by the addition of common salt (0·5—1%) or by immersion, after gauging, in a solution of salt, greater strength being developed, especially during the early stages of hardening. The effect is attributed to the increased solubility of lime in salt solution. Mortar made with ordinary Portland cement and sand was little affected by salt.—F. Sodn.

Patents.

Paving or building blocks [*and iron*] ; *Process for treating fusible domestic and other refuse for obtaining* ——. H. Becker and H. Unger, Berlin, Germany. Eng. Pat. 10,281, May 1, 1913.

The fine material obtained by sifting the refuse is made into briquettes and fused with an excess of coke (in a blast-furnace), so as to produce metallic iron and slag, which latter is drawn off separately and poured into moulds. The product is granular in structure.—F. Sodn.

Artificial marble ; Manufacture of ——. E. Douzal, Paris. Eng. Pat. 22,297, Oct. 3, 1913. Under Int. Conv., May 10, 1913.

Vaseline oil is mixed with a pasty mass, composed of calcium carbonate (preferably crystalline), an oxide and halide or basic halide of a divalent metal (having a "non-coloured" oxide), and water ; lead acetate solution is added, and the mixture cast in moulds, which are coated with a solution of gum lac in sodium borate to render polishing unnecessary. Suitable proportions are—chloride of divalent metal 100, oxide of divalent metal 500, water 150, vaseline oil 75, calcium carbonate 950, and lead acetate 60 grms. Quartz and fluorspar may be added, if desired, and metallic oxides to impart colour. The product is very hard and resists both heat and moisture.—F. Sodn.

Lithographic stones ; Manufacture of artificial ——. V. Hereng, Brussels. Eng. Pat. 5859, March 7, 1914. Under Int. Conv., March 7, 1913. Addition to Eng. Pat. 12,640 of 1913, dated May 30, 1912 (this J, 1913, 82).

One part by weight of white sand is added in making the mixture previously specified.—F. Sodn.

Cementitious compound. D. J. Morris, Assignor to J. E. Carroll, Seattle, Wash. U.S. Pat. 1,096,384, May 12, 1914.

A mixture of 3 parts of magnesia and 1 part of calcium hydroxide.—O. R.

Wood; Impregnation of ——. Hülsberg und Co., Ges. m. b. H. Fr. Pat. 466,263, Dec. 17, 1913. Under Int. Conv., May 8, 1913.

The wood after being subjected to the action of a vacuum, is treated first with steam, then with compressed air; it is next impregnated by liquid under pressure in the usual manner, and again subjected to the action of a vacuum. The wood may also be subjected to the action of a vacuum between the treatments with steam and with compressed air respectively.—H. H. S.

Wear-resisting body [sintered alumina] and method of making the same. C. Dantsizen, Schenectady, N.Y., Assignor to General Electric Co., New York. U.S. Pat. 1,096,688, May 12, 1914.

See Eng. Pat. 4887 of 1912; this J., 1913, 363.—T. F. B.

Production of fat lime for viticulture, agriculture generally, and building purposes. Fr. Pat. 465,851. *See* XVI.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron and steel: Advances in the metallurgy of ——. Sir Robt. Hadfield. Presidential Address, Faraday Soc., June 11, 1914. [Advance proof.] (Pamphlet of 40 pages.)

The following are the subjects of this address consecutively arranged:—(i.) Early metallurgy and alloys of iron and steel. (ii.) Ancient iron and the Delhi Pillar. (iii.) Faraday's experiments in 1822. (iv.) Early workers in scientific metallurgy. (v.) French metallurgy in the 18th and 19th centuries. (vi.) Value of research. (vii.) The author's research work. (viii.) Metallurgy in the middle of last century. (ix.) Steel alloys research. (x.) Science and practice working together. (xi.) Development of research during the last fifty years. (xii.) Special steel alloys. (xiii.) Effect of carbon upon iron. (xiv.) The author's experiments on alloy tool steel. (xv.) Tool steel of lower carbon percentage. (xvi.) The great work of Ledebur. (xvii.) Allotropic theory. (xviii.) The author's papers on alloys of iron. (xix.) Thermal treatment. (xx.) Low temperature experiments in Great Britain and America. (xxi.) Field for research. (xxii.) The non-magnetic and magnetic conditions of manganese steel. (xxiii.) Melting points. (xxiv.) Microscopy (Sorby's work as the originator of metallography). (xxv.) Percy's work. (xxvi.) The art of scientific discovery. (xxvii.) Why research work is so valuable. (xxviii.) The work of the National Physical Laboratory. (xxix.) Past progress in metallurgy. (xxx.) The scope of the University. (xxxi.) The Faraday Society.

Iron ores; Experiments on the reducibility of —— *by flowing gases.* L. Mathesius. Stahl u. Eisen, 1914, **34**, 866—873.

Various raw and calcined ores and briquettes were heated for 5 hours in a current of coal gas at 450°—900° C., and the amounts of metallic iron and ferrous oxide formed determined. Calcined spathose ore was easily reduced; the reducibility of other ores was smaller and roughly proportional to their porosity. The FeO-content of magnetite was hardly affected by the treatment, the ferric oxide being more easily reduced. Ore and flue-dust briquettes were much more easily reduced than ores, over 80% of the iron being reduced to metal at 900° C. Sintering caused an increase in ferrous oxide and decrease in the reduction to metal.—W. R. S.

Cyanidation; Filtering slimes in ——. H. A. Megraw. Eng. and Min. J., 1914, **97**, 1057—1061.

Filtration becomes very difficult when more than 20—30% of colloidal slime is present, and it becomes necessary to add sand. Vacuum or pressure filtration is more economical than the ordinary filter-press. In the movable leaf filter (such as the Moore), a series of leaves is immersed in the tank, and when the cake is formed, the leaves are removed to other tanks for washing. In the stationary leaf type, filtration and washing is effected in the same tank. The Merrill plate-and-frame press, in use at the Homestake mill, has a sluicing bar through the bottom of each frame; after the cake has been made and washed, it is sluiced out by a stream of water. In the Oliver vacuum filter the filtering medium constitutes the face of a drum which revolves in the suspended slime. As the cake emerges it is dewatered by the vacuum and washed by sprays from nozzles attached to the drum. The cake is then detached by reversing the air current. In the continuous decantation process the pulp passes through a series of Dorr thickeners. The thickened pulp is thinned in each case with washing solution, and transferred to another thickener. Where the solution is relatively poor in metal values, final filtration may not be required in this process.—W. R. S.

Silver-silver sulphide; The system ——. C. C. Bissett. Chem. Soc. Trans., 1914, **105**, 1223—1228.

The addition of silver sulphide to silver caused a gradual lowering of the freezing point from 961° C. to 903° C. at about 17% Ag_2S; between 17 and 94% Ag_2S the freezing point was constant (903° C.), practically pure silver separating from the mixtures until a liquid containing 94% Ag_2S remained. Above 94% the freezing point gradually fell to 804° C. at 99% Ag_2S (the mixtures being homogeneous when solidified) and then rose to that of pure silver sulphide (815° C.). No indication was obtained of the existence of any sulphide other than Ag_2S.—W. E. F. P.

Copper; Influence of temperature and pressure on the oxidation of ——. E. Berger. Comptes rend., 1914, **158**, 1502—1505.

Copper oxidises in comparatively dry oxygen at 15° C.; the velocity slowly increases until a certain temperature is reached, when its rise becomes rapid. This temperature depends upon the physical state of the copper, varying from 163° C. in the case of turnings to 71° C. in the case of metal obtained by reducing cupric oxide at 130° C. The experiments were conducted in a V-shaped tube, one limb of which constituted a manometer, the other, containing the copper, being heated by the vapour of a suitable boiling liquid. The velocity is tripled for a 10° C. rise in temperature in the neighbourhood of 170° C. (Cu turnings), and seems to be directly related to the concentration of the film of gas, (pressure), condensed on the metallic surface.—J. L. F.

Copper; Rapid electrolytic separation of —— *from arsenic.* A. Sieverts and W. Wippelmann. Z. anorg. Chem., 1914, **87**, 169—174.

The copper-arsenic alloy is dissolved in nitric acid, the solution evaporated, and the residue, with 2·5 grms. of ammonium nitrate, dissolved in 125 c.c. of 5% ammonia solution. Using concentric gauze-electrodes, the following conditions give a quantitative arsenic-free deposit of 0·3 grm. Cu in 15 minutes at 90° C. from solutions containing 0·22 grm. As:—speed of glass stirrer 500—550 revs. per minute; current density 7·5 amps. per sq. dm. The cathode is washed without breaking the current, dried, and weighed. The arsenic is not reduced and can be determined directly by precipitation by magnesia mixture. It is essential that no trivalent arsenic be present during electrolysis.—T. St.

Aluminium and silicon; The alloys of ——. C. E. Roberts. Chem. Soc. Trans., 1914, **105**, 1383—1386.

Results obtained by the method of thermal analysis and microscopic examination confirmed the conclusions of Fraenkel (this J., 1908, 1023), viz., that the alloys of aluminium and silicon form only a simple eutectic series The eutectic contains about 10% Si and melts at abou 76° C.—W. E. F. P.

Thorium, uranium, zirconium and titanium; Preparation of the elements ——. D. Lely, jun., and L. Hamburger. Z. anorg. Chem., 1914, **87**, 209—228.

The metals were obtained by reduction of the chlorides with sodium in a cylindrical steel bomb, which was exhausted and then heated to 500° C. In the case of titanium the bomb was cooled with alcohol and solid carbon dioxide during exhaustion.

Thorium. The anhydrous chloride was prepared by passing a stream of chlorine and sulphur chloride vapour over the pure oxide at 670° C., and purified by sublimation in a vacuum. Metallic thorium was obtained in grains of different sizes, the largest containing Th 99·9 and O 0·1%. The metal was lead-gray, very ductile, and rubbed down in an agate mortar to a mirror. It could be melted and completely vaporised in a high vacuum on a tungsten support. In the coarse form the metal was unattacked by water, alkali solutions and nitric acid. Warm hydrochloric acid attacked it, and *aqua regia* oxidised it to ThO_2. It oxidised very slowly in the air at the ordinary temperature. The powder had the sp. gr. 11·2. A rod formed by pressure out of grains of about the same size, then rendered conducting by heating for 30 mins. in a vacuum at 1100° C., and sintered by an alternating current in a high vacuum, was exceedingly ductile, even in the cold. *Uranium.* The tetrachloride was prepared by heating the oxide in a stream of sulphur chloride vapour at about 500° C., and purified by sublimation in a porcelain tube at 650°—750° C. in a current of chlorine with which was mixed a little sulphur chloride vapour. The larger metallic grains obtained contained U 99·5 and O 0·5%. The metal was darker in colour and less ductile than thorium; it was not attacked at the ordinary temperature by water, alkali solutions or acetic acid; it dissolved in dilute hydrochloric acid forming UCl_4, and in concentrated hydrochloric acid forming violet UCl_3 which oxidised later to the green UCl_4; nitric acid dissolved it giving yellow $UO_2(NO_3)_2$; the metal became brown in the air. A rod formed by pressure became conducting after heating for half an hour in a vacuum at 1400° C. and could then be sintered into a solid metallic rod. *Zirconium.* The chloride was obtained in a compact crystalline form by passing a very slow stream of chlorine containing carbon tetrachloride vapour (one to two bubbles per second) over the oxide heated to about 800° C. The chloride sublimed to the cooler parts of the tube, kept at about 140° C. The metal was very ductile and was easily obtained in the compact form. It resisted the action of concentrated hydrochloric and nitric acids. Hot *aqua regia*, hot concentrated sulphuric acid, and cold hydrofluoric acid attacked it quickly. *Titanium.* The chloride was obtained by heating 62% ferrotitanium to 400°—500° C. in a current of chlorine, and carefully fractionating the product to a colourless liquid. The metal was less ductile than thorium, zirconium or uranium, and was obtained in rod-form only with special precautions, owing to its ready oxidisability.—T. St.

Reduction of oxides by carbon; Equilibria of ——. R. E. Slade and G. I. Higson. Report of Brit. Assoc., 1913, 450—451.

Vanadium, tantalum, chromium, or tin was heated in an unglazed porcelain boat *in vacuo*, and carbon monoxide was admitted and allowed to react with the metal until the pressure fell to that of equilibrium. Some carbon monoxide was then pumped out and equilibrium attained from the other side. The reactions taking place are of the type: $MO+C \rightleftarrows CO+M$ or $2MO+3C=M_2C+2CO$. The results obtained were:—

	Temperature.	Pressure.
	° C.	mm.
Vanadium	1340	1·5
Tantalum	1270	<0·1
Chromium	1292	6·2
,,	1339	9·2
Tin	750	>760
Tin in presence of SiO_2	753	670

A. S.

Metals and intermetallic compounds; The capacity for heat of —— between 18°—600° C. P. Schubel. Z. anorg. Chem., 1914, **87**, 81—119.

The specific heats of Mg, Al, Cr, Fe, Ni, Co, Sb, Pb, Bi, Cu, Zn, Ag, Sn; Cu_2Mg, Cu_3Al, $CuAl$, $CuAl_2$, Cu_3Sb, Cu_2Sb, $AgMg$, Ag_3Al, Ag_2Al, Ag_3Sb, $MgZn_2$, Ni_2Mg, Ni_3Sn, Co_2Sn, $FeSi$, Ni_2Si, $NiSi$, and Mg_2Si were determined at intervals of 100° C. between 18° and 600° C. From the mean experimental values the true specific heats were obtained graphically. The change of atomic heat with temperature was in general nearly linear above 100° C., both for the pure metals and the compounds. The experimental values for the compounds agreed well with those calculated from the specific heats of the component metals by the rule of Neumann and Kopp.—T. St.

Palladium hydrogen alloys; The specific electrical conductivity and density of ——. G. Wolf. Z. physik. Chem., 1914, **87**, 575—588.

Palladium wire was used alternately as anode and cathode in dilute sulphuric acid for a short time, and then for a longer period as anode. After this treatment it absorbed hydrogen very readily. The conductivity fell progressively with the occlusion of hydrogen, reaching about half its original value at saturation. The curve connecting the conductivity with the hydrogen absorbed consisted of three parts. In the first the diminution was directly proportional to the hydrogen dissolved. In the second the conductivity diminished asymptotically, corresponding to the formation of PdH_2, while in the third, where hydrogen was dissolving in the PdH_2, the diminution again became linear. The density of the alloys diminished with increasing hydrogen content, the curve consisting of two parts. In the first part the gradient was steep and the form of the curve was hyperbolic. In the second the gradient was much smaller and the curve became a straight line.—W. H. P.

Dissociation pressures of some nitrides. Slade and Higson. *See* VII.

Patents.

Steel; Manufacture of ——. G. H. Benjamin, New York. U.S. Pat. 1,095,184, May 5, 1914.

Acid steel obtained by removing silicon and most of the carbon from iron in a converter is refined with a basic slag in a mixer and then treated at a high temperature in a furnace with metallic oxides in an atmosphere of carbon dioxide and nitrogen.—W. E. F. P.

Tool-steel; High-speed ——. R. Furness, Jenkintown, Pa. U.S. Pat. 1,095,842, May 5, 1914.

A steel containing V 1—2 (preferably 1·5), Co 3—7 (4), Cr 2·5—4 (3) and W 16·5—20 (17·5) %.—W. E. F. P.

Iron and steel; Process of treating ——. D. Lamon, Denver, Colo. U.S. Pat. 1,096,006, May 5, 1914.

A mixture of potassium cyanide 1, boric acid 1, and aluminium sulphate ½ part, is used for hardening and toughening iron and steel.—W. E. F. P.

Tin ores; Dressing of ——. W. M. Martin, Redruth. Eng. Pat. 19,514, Aug. 28, 1913.

Carbon dioxide is forced through tin-ore pulp, concentrate, etc., whereby any gelatinous silica present is removed as a lighter product than the gangue, and a better separation of the tin oxide is obtained. The separated gelatinous material is heated to render the silica insoluble, pulverised, and again treated on concentrating tables to recover any tin present. In many cases a better extraction is effected by adding alkali with or after the carbon dioxide.—T. St.

Aluminium alloy and method of producing the same. W. A. McAdams, Bay Shore, N.Y. U.S. Pat. 1,095,653, May 5, 1914.

An alloy of Al 70, Zn 22, Cu 3 and Sb 5, parts by weight. A portion of the aluminium is heated to a high temperature, the copper and then the remainder of the aluminium added, the temperature lowered, the zinc and antimony added, and the mixture agitated.—W. E. F. P.

Filtration of flue dust, fume, and like fine solid impurities from furnace gases. G. Rigg, Palmerton, Pa., Assignor to New Jersey Zinc Co., New York. U.S. Pat. 1,095,676, May 5, 1914.

The gases are passed upwards through a layer of coarse material until an efficient filter is formed by accretion of the solid impurities, after which the conditions are maintained constant by the periodic removal from below of the layers of coarse material which tend to become clogged and by the addition of fresh coarse material at the upper side of the filter.—H. H.

Copper alloys containing a small amount of tin; Process of hardening ——. H. Bryda, Blackstone, Mass. U.S. Pat. 1,095,804, May 5, 1914.

The alloy is filed on the surface while hot, then placed upon a layer of loam "which has not been allowed to come into contact with water or sunshine," allowed to remain until the filed surface becomes bluish, and cooled in a dry place.—W. E. F. P.

Platinum [-tungsten] alloy. E. Weintraub, Lynn, Mass., Assignor to General Electric Co. U.S. Pat. 1,096,655, May 12, 1914.

The malleable alloy, permanent in air and more refractory and harder than platinum, contains Pt 20 to 60 and W 40 to 80%.—B. N.

Furnace; Electric —— with an electric arc or arcs for melting and extraction of metal from ore. P. Krefting, Christiania, Norway. U.S. Pat. 1,097,336, May 19, 1914.

The furnace has a closed melting chamber into which several electrodes project, and a vertical charging shaft above. A flue leads from the melting chamber through the descending charge in the shaft. Several extensions from the shaft communicate with charging apertures, normally closed by the charging material, and conveyers located in the extensions charge the material from the shaft into the melting chamber.—B. N.

Iron; Manufacture of electrolytic ——. Soc. Anon. "Le Fer," Grenoble, France. Eng. Pat. 16,565, July 18, 1913. Under Int. Conv., Aug. 2, 1912.

See Fr. Pat. 458,294 of 1912; this J., 1913, 1115.—T. F. B.

Steel; Purifying ——. E. Humbert, Barleduc, France. Eng. Pat. 18,856, Aug. 19, 1913.

See U.S. Pat. 1,081,532 of 1913; this J., 1914, 86.—T. F. B.

Resistance materials: Production of electrical ——. Resisto-Electrical Manufacturing Co., Ltd., London, and C. Ruzicka, Gravesend, Kent. Eng. Pat. 11,975, May 22, 1913.

A carbide of a metal or metalloid, such as boron, having a comparatively high specific electrical resistance and a melting point above 1500° C., is mixed with a carbide of a metal, such as iron, having a relatively lower specific resistance and a melting point between 800° and 1500° C., and a permanent inert substance, such as felspar, which acts as a conductor of the second class, is relatively neutral to the other substances, and has a melting point below those of the carbides employed. The powdered mixture is fused in a furnace, whilst surrounded by a neutral or reducing gas, at a temperature sufficient to melt the carbide of the metal of lower melting point.—B. N.

Batteries and accumulators; [Packing material for] Electric ——. F. Sablon. Eng. Pat. 16,684, July 21, 1913.

A mixture of a double silicate of magnesium and calcium, such as asbestos, and a trisilicate of magnesium, such as steatite, is baked, and the ceramic mass crushed to fragments about 1 mm. in diameter, these being used for packing primary and secondary batteries to prevent movement of the electrolyte or the plates.—B. N.

Electrode for electric furnaces. A. T. Hinckley, Niagara Falls, N.Y., Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,097,227, May 19, 1914.

The electrode is composed of two parts, one of which has, in one end, a longitudinal hole provided with an annular enlarging groove, with two holes leading from it to the outer surface of the electrode. The second portion has an integral pin, smaller in diameter than the electrode, which fills the hole, and the pin is also provided with an annular groove. A cement ring of conducting material embraces the pin and fills up the grooves.—B. N.

Ozone; Apparatus for the production of ——. J. Steynis. Fr. Pat. 466,029, Dec. 10, 1913. Under Int. Conv., Oct. 27, 1913.

In the apparatus described in U.S. Pat. 1,066,674 of 1913 (this J., 1913, 796) the hollow, cylindrical electrodes and dielectric tubes are so arranged as to be easily removable, and are provided with means for centering and withdrawal in case of breakage. To that end, the top of the outer electrode is provided with a flange, which rests on the casing of the apparatus, and the bottom of the electrode carries a framework fitted with inclined arms, on which the dielectric tube rests and centres itself. A vertical branch extends upwards from the centre of the framework and terminates in an insulating cone, which penetrates and centres the internal electrode.—O. R.

Lead accumulator cells; Solution for use in ——. P. Rabbidge, Neutral Bay, New South Wales. Eng. Pat. 19,782, Sept. 1, 1913. Under Int. Conv, Sept 2, 1912.

See Fr. Pat. 462,663 of 1913; this J., 1914, 322.—T. F. B.

Secondary batteries; Negative electrode for alkaline ——. H. P. R. L. Pörscke and J. A. E. Achenbach, Hamburg. U.S. Pat. 1,096,751, May 12, 1914.

See Eng. Pat. 29,848 of 1912; this J., 1913, 664.—T. F. B.

Electrolytic process and apparatus [for treating alkali salts]. C. White, London. U.S. Pat. 1,096,085, May 12, 1914.

XII.—FATS; OILS; WAXES.

Mowrah fat; The unsaponifiable constituents of —— and the detection of mowrah fat in animal and vegetable fats. P. Berg and J. Angerhausen. Z. Unters. Nahr. Genussm., 1914, **27**, 723—731.

Mowrah fat yields about 2% of unsaponifiable matter having $[\alpha]_D = +27{\cdot}1°$. When the unsaponifiable matter obtained from 100 grms. of the fat is dissolved in 5 c.c. of ether and the solution poured into 100 c.c. of absolute alcohol about 0·3% (calculated on the fat) of a white, amorphous, optically inactive precipitate is obtained. The portion of the unsaponifiable matter soluble in alcohol has the rotatory power $[\alpha]_D = +34°$. The rotations are best observed in chloroform solution. The optical properties of the unsaponifiable matter of mowrah fat may be used for its detection in other fats and oils. The rotatory power of the unsaponifiable matter of lard, for instance, is $[\alpha]_D = -19{\cdot}6°$, whilst that of lard containing 10% of mowrah fat is $[\alpha]_D = +11{\cdot}5°$. The unsaponifiable matter of mowrah fat contains only a very small quantity of phytosterol (recognised by precipitation with digitonin), and Bömer's phytosteryl acetate test yields a negative result. In the case of other fats yielding optically active unsaponifiable constituents, these may be removed by precipitation with digitonin (this J., 1913, 1118) previous to the separation and determination of the optical properties of the remaining substances. A preliminary test for the detection of mowrah fat in lard depends on the partial insolubility of the unsaponifiable matter of the former in alcohol. The unsaponifiable matter is dissolved in a small quantity of ether and the solution is diluted with alcohol; in the case of lard, the mixture remains clear, whilst with lard containing more than 10% of mowrah fat a turbid solution is obtained.—W. P. S.

Jatropha curcas [purging nut] seeds; Toxicity of ——. J. Felke. Landw. Vers.-Stat., 1913, **82**, 427—463. Chem. Zentr., 1914, **1**, 1958—1959.

Curcas (purging nut) oil was separated by treatment with alcohol into a non-poisonous insoluble and a poisonous soluble part. The toxic constituent, *curanolic acid*, was isolated from the soluble portion by stirring with a hot saturated solution of baryta, washing the resulting paste with cold water, drying, extracting with ether, evaporating the ether solution, extracting the residue with absolute alcohol, and treating the alcoholic solution with sulphuric acid. It set to a jelly at about 10° C.

Curcin, the toxic principle isolated from fat-free curcas seeds by extraction with physiological sodium chloride solution, was very sensitive to acid, and had a retarding influence on the coagulation of blood.—A. S.

Cholesterol in fats; Determination of ——. M. Klostermann and H. Opitz. Z. Unters. Nahr. Genussm., 1914, **27**, 713—723.

Whilst about one-half of the cholesterol occurring in blubber oils is present in the form of esters, practically all animal fats are free from cholesteryl esters, the cholesterol being present in the free state, and there is, consequently, no necessity to saponify the fat before the cholesterol is precipitated by means of digitonin (this J., 1913, 1118). In vegetable oils, the greater part of the phytosterol is present in the form of esters and saponification is essential before the whole of the phytosterol can be precipitated by digitonin. Previous saponification is, therefore, also necessary when it is desired to detect vegetable oils in animal fats by means of the phytosteryl acetate test.—W. P. S.

Rice oil and rice fat. J. Davidsohn. Seifenfabrikant, 1914, **34**, 178—179. Chem. Zentr., 1914, **1**, 1788.

On keeping, a solid fat, m.pt. 46° C., separated from rice oil. The characters of the residual liquid oil (water 0·32%) andof the solid fat (water 0·43%) were as follows:—

	Sp. gr. at 15° C.	Butyro-refractometer reading.	Acid value.	Saponif. value.	Iodine value.	Saponifiable matter.
						%
Oil	0·918	67·8 (25° C.)	98·56	198·44	108·5	99·47
Fat	0·924	44·7 (50° C.)	124·30	197·21	74·11	99·43

The oil is suitable for the manufacture of soft, and the fat (the mixed acids from which melt at 39·6° C.) for the manufacture of hard soaps.—A. S.

Beeswax; Use of ozonised air to whiten ——. Times, June 5, 1914. [T.R.]

A plant has been built for the Eparchical Candle Works at St. Petersburg for bleaching beeswax by ozonised air, for use in making church candles. The air is cooled to about 0° C. and passed through a bank of nine ozonisers, each having an electrode area of 40 sq. ft., and supplied with high-tension current at 7000 to 9000 volts by means of three transformers. Each ozonizer takes from 300 to

600 watts, according to the voltage of the secondar current, and the whole plant, which is able to treat one ton of beeswax in a day of 10 hours, requires 10 kw., including the power for the blower and refrigerator.

With energy at 0·6d. per unit the working costs for treating a ton of beeswax are about 5s., exclusive of interest on capital and costs of maintenance, whereas it is stated that with the bichromate method commonly employed for bleaching wax the cost per ton is about £3 15s. The loss of material is said to be practically negligible, and the wax is harder than that bleached by other methods.

Patents.

Oil from seeds and the like ; Apparatus for the extraction of —— by means of a solvent. J. E. McCoid, Kingston-upon-Hull. Eng. Pat. 11,059, May 10, 1913.

Means are provided for tilting the extraction vessels or pots so as to discharge the spent grains, etc. on to a platform. Any material requiring further extraction is then returned to the pots, whilst the remainder is made to fall through a trap-door on to an endless belt or screw conveyor. —C. A. M.

Fats and oils ; Process for improving the odour and taste of vegetable and animal ——. F. Gössel. Ger. Pat. 273,069, May 12, 1912.

Milk, *e.g.*, skim milk, buttermilk, or the like, which has been soured by the bacteriological method, is mixed with the fat or oil and the mixture heated until the water is evaporated and the acid constituents of the milk acquire a brown colour. A portion of the water may be evaporated from the milk, before or after souring, before mixing with the oil or fat. Cocoanut oil treated in this way acquires the odour and taste of freshly rendered lard.—A. S.

Fats and oils ; Process of treating —— in the manufacture of fatty acids and glycerine. E. Twitchell, Wyoming, U.S.A. Eng. Pat. 9160, April 18, 1913.

See Fr. Pat. 456,956 of 1913 ; this J., 1913, 1119.—T. F. B.

Fatty acids and their glycerides ; Process for the reduction of unsaturated ——. W. Fuchs, Vienna. Eng. Pat. 11,543, May 17, 1913. Under Int. Conv., May 18, 1912.

See Fr. Pat. 458,445 of 1913 ; this J., 1913, 1119.—T. F. B.

Oil and like extractors. O. Wilhelm, Stralsund, Germany. Eng. Pat. 25,026, Nov. 3, 1913. Under Int. Conv., Dec. 31, 1912.

Oils ; Process of introducing water-insoluble —— into emulsions or water-soluble bodies. J. H. Smith, La Garenne-Colombes, France. U.S. Pat. 1,096,465, May 12, 1914.

See Fr. Pat. 446,570 of 1911 ; this J., 1913, 150.—T. F. B.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Red lead ; Analysis and composition of ——. A. P. West. Philippine J. Sci., 1913, 8A, 429—437.

An analysis of commercial red lead which is generally regarded as a mixture of Pb_3O_4 and PbO showed a discrepancy of 3·69% Pb between the total Pb found by direct estimation and the Pb calculated from the amounts of free PbO found by leaching out with lead acetate solution, and of Pb_3O_4 obtained by decomposing with nitric acid and weighing the resulting PbO_2. The author considers that red lead consists of PbO in admixture with Pb_3O_4 and Pb_4O_5 and recommends the following methods of analysis. (A) *Insoluble matter* (Baucher's method. Petit, Monit. Pharm., **47**, 2651). 2 grms. are boiled with 100 c.c. of 10% nitric acid for a few minutes, the insoluble PbO_2 formed is reduced with sucrose solution and dissolved in nitric acid, and the insoluble matter is weighed in a Gooch crucible. (B) *Free PbO.* This is best estimated by Lowe's method (Lowe, Dingl. poly. J., 1889, **271**, 472). 0·5 grm. is digested on water-bath for about one hour with 10% lead nitrate solution, boiled for 10 mins., diluted with 2 vols. of hot water, the residue collected and weighed in a Gooch crucible. (C) *(PbO_2+insoluble matter) and (free PbO+combined PbO).* 0·5 grm. of sample is heated with 100 c.c. of 10% nitric acid, the PbO_2 formed+insoluble matter is collected in a Gooch crucible and weighed. The lead in the filtrate is estimated as sulphate in the usual manner and indicates the combined and free PbO in the sample, as Pb_3O_4 and Pb_4O_5 are decomposed by nitric acid in a similar way :—

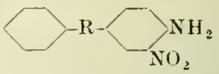
$$Pb_3O_4+4HNO_3 \rightarrow PbO_2+2Pb(NO_3)_2+2H_2O.$$

The amount of free PbO being already known the combined PbO can be calculated. The percentage of PbO_2+combined PbO indicates the percentage of red lead present in the sample. A table is given showing the amount of combined PbO in mixtures of Po_3O_4 and Pb_4O_5 from which the relative percentages of these oxides can be readily found. The total lead in the sample may be determined as sulphate and corresponds very closely with the total lead calculated from the PbO, Pb_3O_4 and Pb_4O_5 as determined by the methods described. For rapid approximate work, it is sufficient to estimate insoluble matter and free PbO ; % red lead=100—(free PbO+insoluble matter). —R. G. P.

Patents.

Pigments ; Manufacture of ——. J. Y. Johnson, London From Badische Anilin und Soda Fabrik, Ludwigshafer on Rhine, Germany. Eng. Pat. 20,106, Sept. 5, 1913.

Compounds of the general formula,



where R represents CO or SO_2, or derivatives of thes compounds substituted in either or both of the benzen nuclei, are mixed with a substratum such as alumina barium sulphate, or china clay to form pigments of clea yellow shades of good colouring power and fast to ligh water, lime, and alcohol. They do not sublime, and, wit few exceptions, are insoluble in oil. They may be used fo colouring paper, or as oil paints, or for lithographic other printing. The preparation of pigments for vario purposes from different sulphobenzide and benzophenoı derivatives is described in detail.—T. F. B.

Paints [for the inside of boiler tubes]. W. Chadd, Wilke Barre, Pa., U.S.A. Eng. Pat. 25,185, Nov. 4, 1913.

Litharge and plaster of Paris (say, equal parts) are inco porated with, say, one-third of their quantity, of rosi and with the desired amounts of boiled linseed oil, drie and pigment, to obtain a paint which is not affected "sulphur water" or strong brine.—C. A. M.

Iron ; Composition for application to —— for the purp of acting as a preservative. A. C. Aglioubz and G. Howkins, Manchester. Eng. Pat. 27,698, Dec. 1913.

A mixture of tar containing creosote oil 40, benzine terebene 1½, turpentine 2, pints, black-lead 2 oz., and desired, "patent driers" ½ lb.—T. St.

Paint ; Method of producing a weatherproof and r preventing ——. M. Brenneisen, Bern, Switzerla Eng. Pat. 4113, Feb. 17, 1914. Under Int. Co Feb. 19, 1913.

Linseed oil varnish (140 grms.) is made into a paste w zinc powder (1 kilo.), and the mass stirred with conc trated hydrochloric acid (180 grms.) and subseque diluted with linseed oil varnish (320 grms.) and turpentine (100 grms.), or the like.—C. A. M.

Resinous products; Manufacture of ——. J. P. A. McCoy, Wilkinsburg, Pa., U.S.A. Eng. Pat. 13,657, June 12, 1913.

See Fr. Pat. 458,904 of 1913; this J., 1913, 1163.—T. F. B.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Insoluble constituent of raw ——, *its isolation and characterisation.* D. Spence and G. D. Kratz. Kolloid-Zeits., 1914, 14, 262—277.

If a small quantity of acid be added to a rubber solution, the viscosity is lowered almost to that of the pure solvent, and from the resulting solution the insoluble nitrogenous constituent of the rubber can be easily separated. The reduction of viscosity is accelerated by sunlight and by heat. The insoluble constituent was separated from a number of different kinds of rubber by a method based on this fact. 100 grms. of washed and dried rubber were treated with 1 litre of benzene containing 0·3—0·5% of trichloroacetic acid and the mixture exposed to sunlight or warmed gently on the water-bath. After about 48 hours, with occasional vigorous agitation, the mixture was allowed to settle, the clear liquid poured off, the insoluble matter extracted twice for several hours with 500 c.c. of benzene containing trichloroacetic acid, then washed with pure benzene, dried, powdered, extracted with benzene to remove the last traces of rubber, washed with alcohol and dried. The insoluble constituent separated in this way from four samples of plantation Para rubber contained: N 9·83, 10·90, 11·58 and 12·08% respectively. It was soluble in a 1% solution of sodium hydroxide, and reprecipitated by dilute acetic or hydrochloric acid. It agreed in nitrogen content and reactions with the glucoproteins. The insoluble constituent from three samples of "hard cure" Para rubber contained: N 7·75, 9·6 and 10·3% respectively. It resembled generally that from plantation Para rubber, but gave reactions for proteins and carbohydrates only after being dissolved in dilute alkali. The insoluble constituent (N about 5%) of balata and specimens of protein (N 9·5 and 11·5%) isolated from *Funtumia elastica* latex also possessed the characters of a complex of protein and carbohydrate. The authors' results, which differ essentially from those of Schmitz (this J., 1913, 499), establish the fact that the nitrogenous constituent of rubber is not a simple protein but a complex of protein and carbohydrate, probably a glucoprotein. The factor 6·25 usually employed for calculating the percentage of insoluble nitrogenous constituent in rubber from its nitrogen-content, gives incorrect results. For Para and plantation Para rubbers a factor of about 10 should be used.—A. S.

Rubber; Vulcanisation of solutions of —— *by means of ultra-violet rays.* A. Helbronner and G. Bernstein. Comptes rend., 1914, 158, 1343—1345.

When a solution of rubber containing sulphur is exposed to the action of ultra-violet light vulcanisation takes place, and a gel is formed the stability of which is so great that not a trace of precipitation occurs on standing for several months, nor on heating for 18 hours at 80° C. On evaporation, however, an insoluble pellicle of vulcanised rubber is left behind. Examination by means of the ultramicroscope shows that there is very little difference in size between the particles present in the vulcanised solution and those in the unvulcanised solution; if anything the latter are slightly smaller and more numerous than the former. Smits and Wiegand have observed that ultraviolet light converts soluble sulphur into the colloidal form which is then precipitated from solution. Since no precipitate or even cloudiness is produced in the presence of rubber, it would appear that it is the insoluble variety of sulphur which in a nascent condition combines with or is adsorbed by the rubber. No vulcanisation takes place unless the sulphur is in solution. The vulcanised material is characterised by the low percentage of combined sulphur (0·6%) necessary for a good product, a fact which recalls the polymerising action of 0·2% of sulphur in the preparation of synthetic caoutchouc from isoprene.—E. W. L.

Rubber; Action of copper and other metals on ——. *I. Cable insulation.* F. Frank and E. Marckwald. Gummi-Zeit., 1914, **28**, 1280—1282.

The destructive action of copper is largely attributed to the wandering of colloidal copper sulphide (cf. Lewis and Waumsley, this J., 1912, 518) due to insufficient vulcanisation, as shown by analyses of cables which had and had not perished: in the former case a very high acetone extract was found. To avoid this effect cable wires should be provided with a good and homogeneous tin coating and the rubber insulating composition should be vulcanised at a high temperature, preferably using basic accelerators, so that the wire inside will not be overheated during the short period required for complete vulcanisation. Under-vulcanisation followed by after-vulcanisation is inadvisable.—H. E. P.

Patents.

Rubber latex; Apparatus for smoking ——. J. S. Cardwell-Quinn, Bello-Horizonte, Brazil. Eng. Pat. 11,424, May 16, 1913.

Latex is supplied to an endless travelling band, on which it is spread uniformly in a thin layer by means of a spreading knife or "doctor" provided with side guides. The endless band passes into the horizontal exit flue of a smoke-generating apparatus where the thin layer of latex is smoked and coagulated, and is afterwards subjected to the pressure of a roller in order to remove excessive moisture. The endless band is supported, where engaged by the spreading knife, between two rollers, by means of an endless rubber apron mounted on these two rollers.
—E. W. L.

Caoutchouc; Process for producing products similar to vulcanised ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 11,209, May 13, 1913.

See Ger. Pats. 266,619, 267,945, 268,387, 268,947, and 269,512; this J., 1914, 93, 94, 269, 365.—T. F. B.

Elastic and plastic substance; Production of an —— J. Stockhausen, Crefeld, Germany. Eng. Pat. 27,663, Dec. 1, 1913. Addition to Eng. Pat. 9264 of 1911, dated April 16, 1910.

See Fr. Pat. 465,306 of 1913; this J., 1914, 558.—T. F. B.

XV.—LEATHER; BONE; HORN; GLUE.

Hides and skins; Second report of the International Commission for the preservation, cure and disinfection of ——. A. Seymour-Jones. Collegium, 1914, 267—277.

Preservation.—The "*Association française pour la destruction du Varron*" have found that one drop of iodine, injected into the tumour caused by the larva of the warble fly, killed the larva, acted as an aseptic and was a more effective method than the old method of squeezing out the larva with the fingers. A more simple method is to pierce the larva with a heated lancet or knitting needle. Birch oil, applied to the sides of the cattle before leaving the sheds for the pastures was effective in preventing the attacks of the warble fly. The removal of larvæ from warbled cattle was always followed by a considerable increase of weight. Fellmongers gathering limes are a great source of trouble to tanners and could advantageously be replaced by clean water to which "Beta-lysol" or "Arasol" had been added. Such materials form no chemical compound with the pelt, arrest all decay and can be completely washed out of the pelt before putting into work. It is suggested that butchers should spray all hides and skins with such a solution after flaying and before salting.

Cure—The successful results obtained by Becker in the laboratory in curing hides with a mixture of salt and soda have been confirmed on the large scale. Many stains are described as salt stains which are of quite a different origin. It is probable that the decomposition products of the albumin form new compounds with the impurities in the salt. Abt has isolated a bacterium which produces a brown colour in the medium on which it is grown and the colour becomes darker as the medium becomes more alkaline by the production of ammonia. The colouring matter is precipitated by iron salts, redissolved by ammonia and contains less nitrogen than peptone. The colouring matter is carried down by gelatinous precipitated phosphate of calcium and if the bacterium is sown on a Petri dish and in other parts a precipitate of calcium phosphate is produced the greater part of the colouring matter is attracted to the precipitate. In the formation of a salt stain the brown colouring matter produced by the bacteria would be fixed by the calcium phosphate produced from calcium sulphate in the salt; in other cases it would be precipitated by the iron salts derived from the hæmoglobin, etc. Abt has also isolated a streptothrix, a variety of *Actinomyces chromogenes* Gasperini, which produces a colouring matter of similar nature. All bacteria which colour culture media without being coloured themselves, are capable of producing salt stains. "Pir-holes" are of quite a different origin from salt stains and are produced by the crystallisation of salt in the grain thereby breaking it. Salt stains are less common when sea salt is used than when rock salt is used; the latter contains calcium sulphate. A process in which the grains of calcium sulphate were allowed to settle to the bottom of the brine gave the fewest stains. No better results were obtained by adding 4% of sodium carbonate to the salt. The use of salt of 99·9% purity, which has lately come into commerce, is recommended.

Disinfection.—Abt found that chlorine was not a satisfactory disinfectant and sterilisation was never obtained with mustard oil. Seymour Jones' formic mercury process gave good results and the Schattenfroh-Kohnstein method was efficient, but was harmful to the skin. As a preventative treatment to be applied to all dried skins the Seymour-Jones' method is recommended provided that depilation is carried out with pure lime, with lime and arsenic sulphide or with concentrated sodium sulphide solution. Yocum condemns the official methods of the U.S. Government on account of inefficiency or destruction of hide substance. Disinfection with carbolic acid, sulphur dioxide and mercuric chloride are condemned for the same reasons. Röhm has patented the use of solutions of copper salts, containing the metal in the form of complex ions, as a method of disinfection.—D. J. L.

Tannins; Pseudo —— in sulphite cellulose extracts. W. Moeller. Collegium, 1914, **5**, 319—324.

Wood pulp liquor produced as a by product in the manufacture of cellulose by the soda process has quite different properties from that from the sulphite process. The liquor from the latter process contains much lime and sulphurous acid, which must be removed before it can be used as a tanning material; all wood pulp extracts produced in Germany are of this variety. Liquors from the soda process only require to be neutralised with a weak acid before use. All cellulose extracts have about 15% of ash and this is included in the total soluble matter. They also contain quantities of non-tannins such as resin, sugar, etc., which must also be reckoned as useless when the cost price is calculated. All these non-tannins remain in the liquors when cellulose extract is used mixed with other materials and accumulate in the suspender liquors to such an extent that they can only be run away. Molasses, cane sugar and glucose are much cheaper to use for weighting leather than cellulose extract. Even when used as a weighting material only, scarcely 50% of the total soluble matter of cellulose extract is utilised.—D. J. L.

Sulphite cellulose extract; Detection of ——. A. Gansser. Collegium, 1914, **5**, 324—325.

Moeller (this J., 1914, 365) and Loveland (this J., 1913, 373) have been unable to confirm the author's results in the detection of cellulose extract in the extract from leathers on which it has been used (Collegium, 1912, 482). It must be assumed that there are some cellulose extracts which do not give the Procter-Hirst reaction (this J., 1909, 293) and Becker has shown that such extracts may be produced. Quebracho wood which is kept away from light and air and under the action of mould growths will give the Procter-Hirst reaction.—D. J. L.

Leather liming control; Light ——. J. T. Wood. Collegium, 1914, 305—311.

A report of further work done on the subject since the last report presented at the London Conference of the I.A.L.T.C. in 1912 (this J., 1912, 446). Giusiana (this J., 1912, 1192) states that the addition of magnesium and ammonium salts to the lime liquor results in a fine grain and suggests the following composition of a lime liquor where it is not desirable to swell the skin: Na_2S, 5; $CaCl_2$ (cryst.) 8·7; $MgCl_2$ 8·05, NH_4Cl 2·1 and $BaCl_2$ 9·65 kilos. per 100 litres. From the preliminary report by the author and D. J. Law (*loc. cit.*) it was found that the greatest amount of nitrogen is dissolved out of the goods in the first draw and that there is a definite amount of nitrogenous substance which the limes are capable of extracting from the skin. Nitrogen in a lime liquor up to 0·2 grm. per litre is not detrimental but it depends upon other factors such as temperature, degree of breaking down of the proteins and number of proteolytic bacteria present, so each case must be judged on its merits. R. F. Innes has found as much as 14% CaO in a fully limed goat skin but no regular curves of absorption of lime could be obtained; the ash usually contained 65—75% CaO. The author has found, in the case of sheep skins that have been over-limed, that in the early stages of liming the hyaline layer is not attacked by tryptic enzymes even by long exposure to their action but, after a certain time in lime, these enzymes are capable of attacking this layer. Stiasny made experiments with the stalagmometer on old lime liquors, the number of drops falling showing the surface tension (σ) and the time required for emptying the tube showing the viscosity (η). Peptones and glycocoll (as representative of amino acids) diminished the surface tension but did not increase the viscosity. Inorganic substances (lime, sulphide, etc.) had no influence on either the surface tension or the viscosity. Gelatin slightly increased the surface tension, very dilute solutions being relatively more effective than strong ones, and considerably increased the viscosity. Mixtures of Witte peptone and gelatin showed also the great influence of peptones on the surface tension and their small influence on the viscosity, and the small influence of gelatin on the surface tension and its great influence on the viscosity. Measurements of σ and η for old and medium limes are given.—D. J. L.
